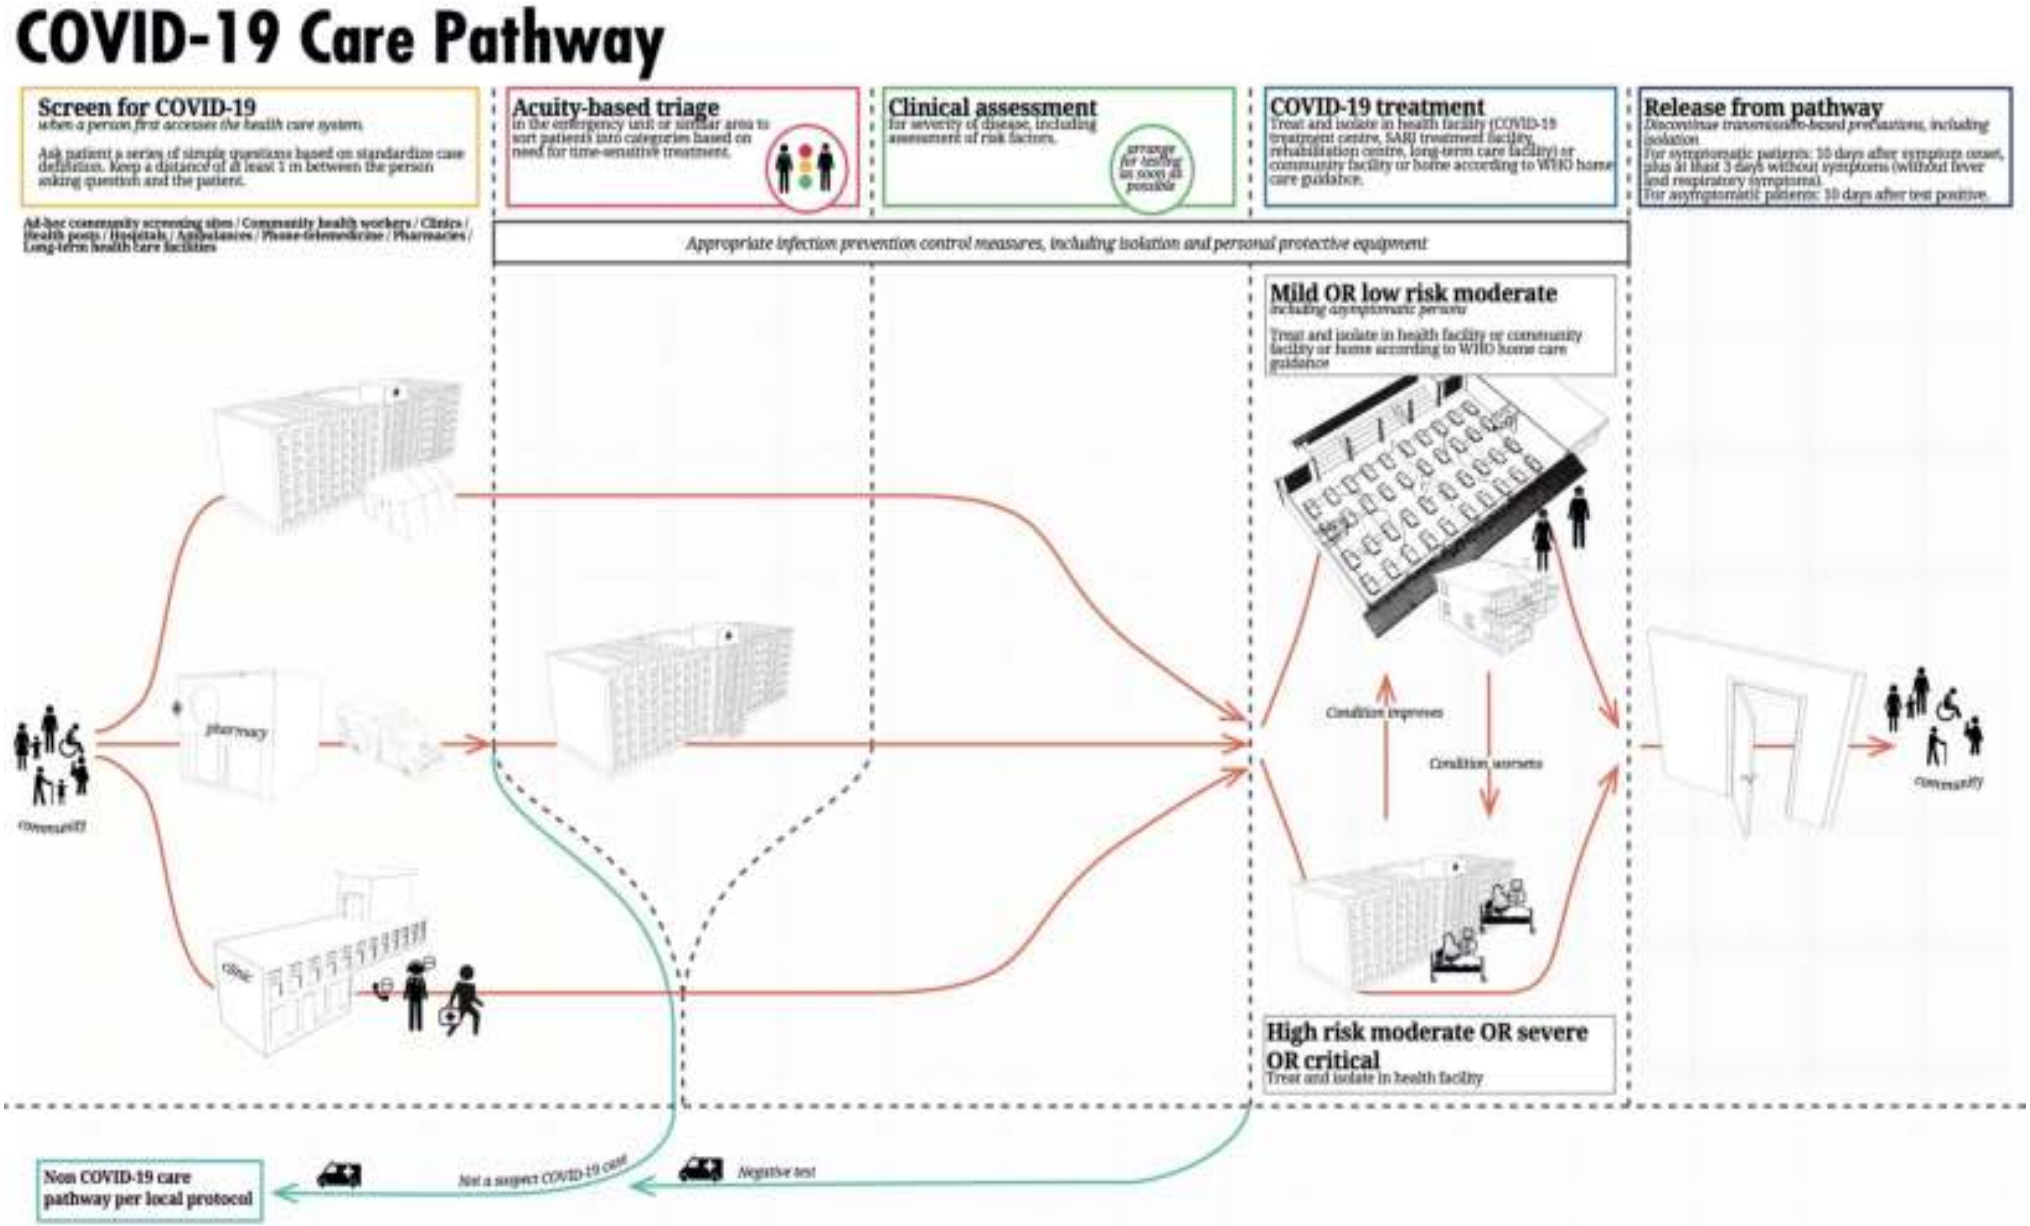
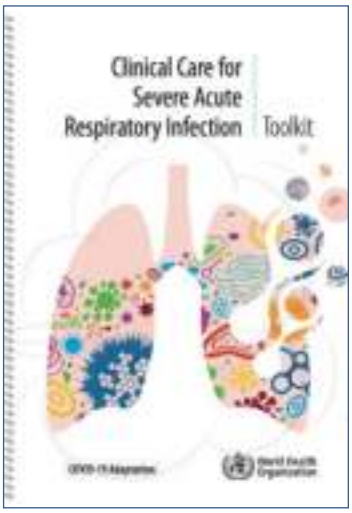
Annex 1: COVID-19 care pathway



Annex 2: Resources for supporting clinical management of COVID-19



Clinical care for severe acute respiratory infection toolkit: COVID-19 adaptation (2020)
This toolkit is intended for clinicians working in acute care hospitals in low- and middle-income countries, managing adult and paediatric patients with acute respiratory infection, including severe pneumonia, acute respiratory distress syndrome, sepsis and septic shock. The main objective is to provide some of the necessary tools that can be used to care for the critically ill patient from hospital entry to hospital discharge.

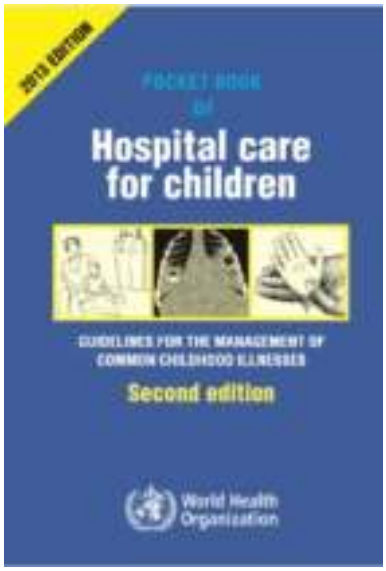
IMAI District clinician manual: hospital care for adolescents and adults. Guidelines for the management of common illnesses with limited resources (2011)
The manual is written for clinicians working at the district hospital (first-level referral care) who diagnose and manage sick adolescents and adults in resource-constrained settings. It aims to support clinical reasoning, and to provide an effective clinical approach and protocols for the management of common and serious or potentially life-threatening conditions at district hospitals. The target audience includes doctors, clinical officers, health officers and senior nurse practitioners. It has been designed to be applicable in both high and low HIV prevalence settings.
https://www.who.int/hiv/pub/imai/imai2011/en/

WHO-ICRC Basic emergency care: approach to the acutely ill and injured (2018)
Developed by WHO and ICRC, in collaboration with the International Federation for Emergency Medicine, *Basic emergency care (BEC): approach to the acutely ill and injured* is an open-access training course for frontline health care providers who manage acute illness and injury with limited resources. The BEC package includes a Participant Workbook and electronic slide decks for each module. Integrating the guidance from WHO Emergency Triage, Assessment and Treatment (ETAT) for children and the Integrated Management of Adult/Adolescent Illness (IMAI), BEC teaches a systematic approach to the initial assessment and management of time-sensitive conditions where early intervention saves lives.
https://www.who.int/publications/i/item/basic-emergency-care-approach-to-the-acutely-ill-and-injured



Pocket book of hospital care for children: guidelines for the management of common childhood illnesses (second edition) (2013)
For use by doctors, nurses, and other health workers caring for children at first-level referral hospitals with basic laboratory facilities and essential medicines. These guidelines focus on the management of the major causes of childhood mortality in most developing countries, including pneumonia, and also cover common procedures, patient monitoring, and supportive care on the wards.
https://www.who.int/maternal_child_adolescent/documents/child_hospital_care/en/

Oxygen therapy for children (2016)
A bedside manual for health workers to guide the provision of oxygen therapy for children. The manual focuses on the availability and clinical use of oxygen therapy in children in health facilities to guide health workers, biomedical engineers and administrators. It addresses detection of hypoxaemia, use of pulse oximetry, clinical use of oxygen, delivery systems, and monitoring of patients on oxygen therapy. The manual also addresses the practical use of pulse oximetry, and oxygen concentrators and cylinders.
http://www.who.int/maternal_child_adolescent/documents/child-oxygen-therapy/en/

Technical specifications for oxygen concentrators (2015) Provides an overview of oxygen concentrators and technical specifications to aid in selection, procurement, and quality assurance. It highlights the minimum performance requirements and technical characteristics for oxygen concentrators and related equipment that are suitable for the use in health facilities.
https://www.who.int/medical_devices/publications/tech_specs_oxygen-concentrators/en/

WHO-UNICEF technical specifications and guidance for oxygen therapy devices (2019)
The purpose of this document is to increase access to quality products to ensure the supply of oxygen, especially in low- and middle-income countries and low-resource settings within countries from all income groups. It aims to support ministries of health to ensure that oxygen supply is available, as well as to raise awareness of the importance of appropriate selection, procurement, maintenance, and use of medical devices, both capital equipment and single-use devices.

Interim Guidance on Duration of Isolation and Precautions for Adults with COVID-19

Last Updated July 22, 2021

Summary of Recent Changes

Updates as of February 13, 2021

As of February 13, 2021

- Added recommendations for duration of isolation and precautions for severely immunocompromised adults.
- Added information on recent reports of variants of concern in the United States.

Assuming evidence supports ending isolation and precautions for adults with any disease severity 10 days after symptom onset, CDC is considering updating its recommendations to state that fever should resolve and symptoms recommended to present transitional or mild (i.e. not severe, like shortness of breath, prolonged isolation and unnecessary use of laboratory testing. Recommendations for ending isolation and precautions should be date and not a calendar date, to avoid confusion.

CDC recommends that all people, regardless of symptoms and regardless of whether or not they have been tested for recent COVID-19 in the past, continue to use all recommended prevention strategies (i.e., wear masks, stay at least 6 feet away from others, avoid crowds, and wash hands frequently).

Ministry of Health

COVID-19 Quick Reference Public Health Guidance on Testing and Clearance

This information can be used to help guide decision making on testing and clearance of contacts of cases or individuals suspected or confirmed to have COVID-19. This information is current as of March 5, 2021 and may be updated as the situation on COVID-19 continues to evolve. At this time, there are no changes to the routine management of COVID-19 cases or contacts based on their vaccination history. This will be re-evaluated and updated as further information is available.

Who should be tested for COVID-19?

Please refer to the COVID-19 Provincial Testing Guidance Update.

Diagnosing COVID-19

Please refer to the current Ontario Case Definition for information on confirmed, probable and reinfection cases.

Please refer to Public Health Ontario Test Information Sheets on:

- COVID-19 – PCR
- COVID-19 – Serology
- COVID-19 – Variant of Concern (VoC) Surveillance

For details on the assessment of laboratory results in the context of the clinical and epidemiological context of an individual, please refer to the Management of Cases and Contacts of COVID-19 in Ontario.

Point-of-care (POC) testing refers to testing that employs a COVID-19 medical device authorized by the Minister of Health (Canada) for point-of-care use and is also often referred to as 'rapid testing'. Some point-of-care testing (POCT) assays, both molecular and antigen tests, are now approved by Health Canada. All antigen POCT results that are preliminary positives require parallel or confirmatory testing at a licensed laboratory. All POCT preliminary positives and final positives from antigen and molecular tests must be reported to the local public health unit according to the *Health Protection and Promotion Act* (HPPA) and are actionable for initiating clinical and public health management (see Appendix 9: Management of Individuals with Point of Care Results). However, the confirmatory laboratory test result should be used to direct final clinical and public health management. False negatives may be more likely with POCT assays than laboratory-based assays. Depending on the clinical context of testing, final positive and negative POCT results may still require parallel/repeat testing using a laboratory-based NAAT to guide case and public health management (see Appendix 9: Management of Individuals with Point of Care Results for more details).

Asymptomatic testing for COVID-19

- An asymptomatic individual who has been advised by local public health to get tested due to exposure to a case or as part of an outbreak investigation should be tested within 14 days from their last exposure.
    - If the contact has their negative specimen collected on day 0 to day 6 of their quarantine period, they should repeat specimen collection on or after day 10 of their 14 day quarantine period. If the contact has their negative specimen collected on day 7 to day 14, then repeat testing is not recommended.
    - Contacts must remain in quarantine for the full 14 days from last exposure, regardless of negative test results.
    - Re-testing should be conducted if the asymptomatic individual who initially tested negative develops symptoms consistent with COVID-19.

Reinfection

- Re-testing after clearance should be based on clinical indications for testing (e.g., in the context of new symptoms compatible with COVID-19), or as directed in the context of new high-risk exposures or outbreak investigations.
- An asymptomatic individual that **previously had laboratory-confirmed COVID-19 AND was cleared**, should generally **not be re-tested** for asymptomatic surveillance purposes due to persistent shedding.
- Previously cleared individuals should continue to follow public health guidance for COVID-19 prevention, including self-isolating after new high risk exposures to unrelated cases.

- If there is uncertainty as to whether a new positive after clearance represents a potential new infection or persistent shedding, repeat testing as soon as possible.
- For confirmation of reinfection, please follow the **Ontario Case Definition**.

Criteria for when to discharge someone with probable or confirmed COVID-19 from isolation

- For each scenario, isolation after symptom onset should be for the duration specified **provided that the individual is afebrile (without the use of fever-reducing medications), and symptoms are improving for at least 24 hours**. Absence of cough is not required for those known to have chronic cough or who are experiencing reactive airways post-infection.
- If an individual has tested positive but has never had symptoms, isolation recommendations should be **based on date of specimen collection**.
- If an asymptomatic individual has tested positive AND has a prior history of symptoms compatible with COVID-19, clearance should still be based on specimen collection date. At the discretion of the local public health unit, the period of communicability and clearance may be based on symptom onset date depending on timing of symptoms (e.g., recent symptoms) and likelihood that symptoms were due to COVID-19 (e.g., known exposure to a confirmed COVID-19 case prior to symptom onset).
- After an individual completes their isolation period, they should continue to practice physical distancing measures and use of masking for source control as recommended for everyone at this time.

Approaches to Clearing Cases (including cases with variants of concern)

Approach	When to Use	Instructions
Non-Test Based Waiting **10 days** from symptom onset (or 10 days from specimen collection date if persistently asymptomatic)	Mild to moderate illness AND no severe immune compromise	Can discontinue isolation after **10 days from symptom onset** (or 10 days from positive test collection date if never had symptoms), provided that the individual is afebrile (without the use of fever-reducing medications) and symptoms are improving for at least 24 hours. Absence of cough is not required for those known to have chronic cough or who are experiencing reactive airways post-infection. Mild to moderate illness includes the majority of cases of COVID-19, and includes all those who do not meet the definition of severe illness or severe immune compromise (below).
Non-Test Based Waiting **20 days** from symptom onset (or 20 days from specimen collection date if asymptomatic and severe immune compromise)	Severe illness (requiring ICU level of care) **OR** severe immune compromise	Can discontinue isolation **20 days from symptom onset** (or 20 days from positive test collection date if asymptomatic and severe immune compromise), provided that the individual is afebrile (without the use of fever-reducing medications) and symptoms are improving for at least 24 hours. Absence of cough is not required for those known to have chronic cough or who are experiencing reactive airways post-infection. Studies informing this approach did not have a consistent definition of severe illness or severe immune compromise. For the purposes of a clearance assessment: • **Severe illness** is defined as requiring ICU level of care for COVID-19 illness (e.g., respiratory dysfunction, hypoxia, shock and/or multi-system organ dysfunction). • Examples of **severe immune compromise** include cancer chemotherapy, untreated HIV infection with CD4 T lymphocyte count <200, combined primary immunodeficiency disorder, taking prednisone >20 mg/day (or equivalent) for more than 14 days and taking other immune suppressive medications. • Factors such as advanced age, diabetes, and end-stage renal disease are generally not considered severe immune compromise impacting non-test based clearance.

Approach	When to Use	Instructions
Test Based Two consecutive negative specimens tested by a NAAT, collected at least 24 hours apart	Not routinely recommended, but may be used at the discretion of a hospital to discontinue precautions for admitted patients	Continue isolation until **2 consecutive negative specimens tested by a NAAT and collected at least 24 hours apart**. • Testing for clearance may begin after the individual has become afebrile and symptoms are improving for at least 24 hours. Absence of cough is not required for those known to have chronic cough or who are experiencing reactive airways post-infection. • If swab remains positive, test again in approximately 3-4 days. If swab is negative, re-test in 1-2 days (and at least 24 hours apart). • Tick the box labelled 'Other' and clearly write 'For clearance of disease' on the PHO Laboratory COVID-19 Test Requisition, or clearly write this on the requisition if submitting to another laboratory. • Serological testing cannot be used for test based clearance. • Test based clearance should not be used in an attempt to reduce the length of isolation.

Recommendations for Health Care Workers Return to Work

- Health care workers (HCWs) should follow **isolation and clearance with a non-test based approach;** if they have required hospitalization during the course of their illness, a test based approach may be used at the discretion of the hospital while they are admitted (see above). Some HCWs may be directed to have test based clearance by their employer/Occupational Health and Safety.
- Symptomatic HCWs awaiting testing results must be off work
- Asymptomatic HCWs awaiting testing results may continue to work using the appropriate precautions recommended by the facility, which will depend on the reason for testing (i.e., asymptomatic HCW is not on self-isolation following a high-risk exposure)
- Asymptomatic HCWs exposed to a symptomatic household member should isolate until the symptomatic individual has received a negative COVID-19 test result or an alternative diagnosis from their healthcare provider. If testing is not conducted then the HCW should self-isolate for 14 days from last exposure.

In **exceptional circumstances** where clinical care would be severely compromised without additional staffing, an earlier return to work under work self-isolation may be considered for an asymptomatic HCW who is self-isolating due to a high-risk exposure.

In **exceptionally rare circumstances** where clinical care would be severely compromised without additional staffing, an earlier return to work of an asymptomatic COVID-19 positive HCW that has not been cleared may be considered under work self-isolation recognizing the HCW may still be infectious (see table below). Any COVID-19 positive worker who is, in an exceptionally rare circumstance, being allowed to return to work earlier than would otherwise be the case must not pose a risk to other workers or patients.

Work self-isolation means maintaining self-isolation measures outside of work for 14 days from their last exposure (for contacts with high-risk exposures); or 10 days from symptom onset (or 10 days from positive specimen collection date if consistently asymptomatic) for cases. While at work, the HCW must adhere to universal masking recommendations, maintain physical distancing (remaining greater than 2m/6 ft from others) except when providing direct care, and perform meticulous hand hygiene. These measures at work are required to continue until non-test based clearance (or test based clearance if required by employer/Occupational Health and Safety). The COVID-19 positive HCW should ideally be cohorted to provide care for COVID-19 positive patients/residents if possible. The HCW on work self-isolation should not work in multiple locations.

Work Self-Isolation Guidelines

Symptoms at/around time of testing	Test Result	Instructions
Yes	Positive	• Work self-isolation could start after a minimum of 72 hours after illness resolving, defined as resolution of fever (without the use of fever-reducing medications) and improvement in respiratory and other symptoms
Yes	Negative	• May return to work 24 hours after symptom resolution • If the HCW was self-isolating due to an exposure at the time of testing, return to work should be under work self-isolation until 14 days from last exposure
Never symptomatic at time of test	Positive	• If there has been a recent potential exposure (e.g., tested as part of an outbreak investigation or other close contact to a case), work self-isolation (i.e., return to work) could start after a minimum of 72 hours from the positive specimen collection date to ensure symptoms have not developed in that time, as the positive result may represent early identification of virus in the pre-symptomatic period • If there is a low pre-test probability (e.g., there has been no known recent potential exposures such as tested as part of surveillance and no other cases detected in the facility or on the unit/floor, depending on the facility size), see Public Health Management of Cases and Contacts of COVID-19 in Ontario for repeat testing guidance. If follow-up testing is negative, the HCW is cleared and can return to work as per usual.

Recommendations for Return to Work in Non-Health Care Settings

- Return to work for workers who are confirmed or probable cases and work in non-health care settings requires clearance as outlined earlier in this document and in the Public Health Management of Cases and Contacts of COVID-19 in Ontario guidance.
- Workers are not required to provide proof of a negative test result (by NAAT) or a positive serological test result to their employers in order to return to work. It is expected that workers who have tested positive abide by public health direction and advice on when they would be considered clear to return to work.
- Return to work for workers who are self-isolating due to a high-risk exposure can occur after the end of their self-isolation period.
- Asymptomatic workers exposed to a symptomatic household member should isolate until the symptomatic individual has received a negative COVID-19 test result or an alternative diagnosis from their healthcare provider. If testing is not conducted then the worker should self-isolate for 14 days from last exposure.

Work Self-Isolation in Non-Health Care Settings

- Work self-isolation should NOT be considered for confirmed or probable COVID-19 cases in non-healthcare settings (including asymptomatic positive workers within their isolation period), for large workplace outbreaks, for large numbers of exposed workers in a given workplace, or for any worker linked to an outbreak where workers also live in a congregate living setting.
- There may be **exceptional circumstances** where the Public Health Unit may consider work self-isolation for workers who are in self-isolation from a high-risk exposure, excluding the scenarios outlined above. This should be done in consultation with the Ministry Emergency Operations Centre and Public Health Ontario.
- Work self-isolation is generally **not** recommended for any workers in non-healthcare settings due to the potential for contacts with high risk exposures to be infectious, and barriers to ensuring appropriate and consistent infection prevention and control measures to prevent transmission.
    - Considerations for exceptional circumstances could include:
        - health and safety, and ethics and equity, including whether the worker(s) serve a “critical” function, and promoting the well-being of and minimizing harm to the self-isolating worker, other workers and the community
        - minimizing risk related to transportation to and from work (e.g., no carpooling / ride-sharing or public transit use); the availability of alternatives to work-self isolation (e.g., work from home, alternate staff)
        - availability of in-house supports for training and monitoring of correct PPE use at the workplace

        - whether required IPAC measures can be implemented including whether there are barriers to measures such as: symptom screening, physical distancing, appropriate PPE use and masking for source control
    - To be in compliance with the Occupational Health and Safety Act, the employer must take into consideration the safety of all workers and take all steps reasonable in the circumstances to protect their workers.

Appendix 9: Management of Individuals with Point-of-Care Testing Results

Version 3.0 March 5, 2021

Key Updates

- Updated Table 1 & 2 (page 4-6)
- Updates to reflect changes to LSCCLA and HPPA for point-of-care testing (throughout)
- Minor updates to Public Health Management section (page 7-8)

Point-of-care testing (POCT) refers to testing that employs a COVID-19 medical device authorized by the Minister of Health (Canada) for point-of-care use and is also referred to as 'rapid testing'. Some POCT assays, both molecular and antigen tests, are now approved for use by Health Canada and available in Ontario. This Appendix to the Management of Cases and Contacts of COVID-19 in Ontario provides information on the public health management of SARS-CoV-2 results from POCT assays.

Notification to the Public Health Unit

- A positive result issued from an **antigen** POCT assay is considered a **preliminary positive result** and must be reported to the local public health unit (PHU), in accordance with the *Health Protection and Promotion Act*.
- Where a Health Canada approved **molecular POCT** assay has been reviewed and approved for final reporting by the Ministry of Health, results can be issued and reported to the local public health unit as **final.**
    - See Table 1 below for the specific clinical scenarios where a POCT final report can be issued. Molecular POCT assays currently being deployed by the Ministry of Health include: GeneXpert® Xpress SARS-CoV-2 and ID NOW™ COVID-19.
    - All positive molecular COVID-19 POCT results must be reported to the local PHU in which the person from whom the specimen was taken resides, in accordance with the *Health Protection and Promotion Act*.

    - Physicians and practitioners performing antigen or molecular COVID-19 POCT are required under section 25 of the *Health Protection and Promotion Act* to report positive COVID-19 test results, including a preliminary positive result from antigen POCT, as soon as possible after the positive test result is obtained.
    - Laboratory operators are required under section 29 of the *Health Protection and Promotion Act* to report positive COVID-19 test results as soon as possible after the positive test result is determined.
- Where possible, results from molecular COVID-19 POCT should be entered into the Ontario Laboratories Information System (OLIS) for reporting to the PHU through Case and Contact Management. If OLIS entry is not possible, individuals performing COVID-19 molecular POCT must report all positive results directly to the local PHU through an alternate secure manner (e.g., electronic fax).

Confirmatory Testing for POCT Assays

- Any positive **antigen** COVID-19 POCT result is considered preliminary, regardless of the setting it is obtained in, and requires additional testing such as parallel (i.e. dual swab collection at the same time as POC specimen collection) or repeat (i.e. subsequent swab collection following POC testing) testing using a laboratory-based nucleic acid amplification test (NAAT).
- Health Canada-approved molecular COVID-19 POCT for which positive results have been approved as final by the Ministry of Health do not necessarily require confirmatory testing, and are sufficient for classifying the case as 'confirmed'. However, additional testing may be recommended for further clinical/public health management of the case (see Table 1 below).
- **Additional testing using a laboratory-based NAAT is recommended in the following scenarios**:
    - **Negative** molecular POCT result in **high** pre-test probability settings. These include :
        - persons (symptomatic or asymptomatic) who are contacts of confirmed cases;
        - symptomatic persons tested when community prevalence is high (e.g. >10% of NAAT tests are SARS-CoV-2 positive);

        - symptomatic persons beyond the early phase of illness (e.g., beyond 7 days of symptom onset).
    - **Positive** molecular COVID-19 POCT result in symptomatic or asymptomatic persons in an **isolated or remote** community for which the positive molecular COVID-19 POCT result is the first recent positive case identified in the community.
    - All POCT done in the setting of an **outbreak**, including symptomatic or asymptomatic patients. Parallel collection should be performed in this scenario.
- For more guidance on interpretation of POCT results and when parallel or subsequent repeat testing is recommended, see the MOH's COVID-19 Quick Reference Public Health Guidance on Testing and Clearance and the COVID-19 Provincial Testing Guidance Update.

Case Classification

- Additional testing for confirmation through standard laboratory-based NAAT testing should be obtained for preliminary positive results from antigen COVID-19 POCT assays until further evaluation of their test performance.
- Final case status (Probable, Confirmed or Does Not Meet Case Definition) should be based on the confirmatory laboratory-based NAAT result, and the timing of that specimen relative to the initial specimen collection (see Table 1 below).

Table 1: Interpretation and Classification of Results from Molecular Point-of-Care Testing (POCT) Assays Approved for Final Reporting

Clinical/Exposure History	Final Molecular POCT Result*	Initial Case Classification	Confirmatory laboratory NAAT result	Final Case Classification
Symptomatic individual without known contact with a positive case (includes school-aged children with 1 or more symptoms)	Positive	Confirmed	Not required, but if collected and indeterminate	Confirmed case
			Not required, but if collected within 24 hours of POC test and is negative***	Does not meet case definition
	Negative	Does not meet case definition**	Not required, but if collected and is positive	Confirmed case
			Not required, but if collected and indeterminate	Probable case
			Not required, but if negative or invalid	Does not meet case definition
Any individual (symptomatic or asymptomatic) with known contact with a positive case	Positive	Confimed	Not required, but if collected and is positive, indeterminate, or invalid	Confirmed case
			Not required, but if collected within 24 hours of POC test and is negative***	Does not meet case definition
	Negative	N/A	Confirmatory testing is required, and if positive	Confirmed case
			Confirmatory testing is required, and if negative	N/A- Individual remains as a contact
			Confirmatory testing is required. If not performed or indeterminate, repeat confirmatory testing	N/A - Individual would remain as a contact until repeat test result is available

Clinical/Exposure History	Final Molecular POCT Result*	Initial Case Classification	Confirmatory laboratory NAAT result	Final Case Classification
Asymptomatic individual without known contact with a positive case	Positive	Probable	Confirmatory testing is required, and if positive	Confirmed case
			Confirmatory testing is required, if collected within 24 hours of POC test and is negative***	Does not meet case definition
			Confirmatory testing is required and is indeterminate or invalid	Probable case
	Negative	N/A	N/A	Does not meet case definition

* If POCT result is 'invalid', repeat testing as per manufacturer's direction

**Consideration should be given to clinical and/or exposure history, disease prevalence in the community, and the risk/vulnerability of the population to determine if confirmatory testing is warranted in these scenarios.

*** Confirmatory testing that is negative, and obtained >24 hours after a positive POCT specimen, may represent a true change in case status (positive to negative), or that the POCT positive result was a false positive. Interpretation and subsequent case management should be based on the context of the case, and their clinical and epidemiological situation.

Table 2: Interpretation and Classification of Results from Antigen Point-of-Care Testing (POCT)

Description	Antigen POCT Result*	Initial Case Classification	Confirmatory Laboratory NAAT Result**	Confirmatory specimen obtained ≤24 hours after specimen for preliminary result	Final Case Classification
Asymptomatic individual without known contact with a positive case (screening test)	Positive	Probable	Positive	Yes or No	Confirmed case
			Negative	Yes	Does not meet case definition
			Negative	No	Probable***
			Not performed or invalid	N/A	Probable
	Negative	Does not meet case definition	Not required or recommended, but if collected and test is negative	Yes or No	Does not meet case definition
			Not required or recommended, but if collected and test is positive	Yes or No	Confirmed case

* If POCT result is 'invalid', repeat testing as per manufacturer's direction

** If confirmatory test is 'indeterminate', follow public health case and contact management guidance on the management of indeterminate results.

*** Negative confirmatory laboratory-based specimens collected >24 hours after preliminary positive specimen should be interpreted in the context of the time between the initial preliminary positive and confirmatory specimen, and the pre-test probability of the individual based on their clinical and epidemiological context.

Public Health Management

- A **final positive** result from a Health Canada approved molecular COVID-19 POCT assay should be classified as a **confirmed case** of COVID-19 and PHUs should conduct case and contact management.
- A **positive result** on a serology POCT does not need to be reported to or actioned by the PHU.
- A **preliminary positive** result from a Health Canada approved antigen COVID-19 POCT assay should be considered a **probable case** of COVID-19 and PHUs should initiate case and contact management while awaiting confirmatory test results.
    - Probable cases should be advised that confirmatory testing is pending, and if confirmatory testing is negative, they may discontinue self-isolation as per the Quick Reference Guidance on Testing and Clearance.
    - Contacts of these probable cases should be advised that confirmatory testing is pending, and if confirmatory testing is negative, they may no longer be considered a contact and can discontinue self-isolation.
    - Preliminary positives should initiate outbreak assessment/management actions as appropriate to the case and context, and in a manner that they may be quickly discontinued if confirmatory testing is negative.
- If confirmatory testing is negative, from a specimen obtained ≤24 hours after the specimen was obtained for the preliminary positive result, PHUs should update the case classification from probable to '**Does not meet'** case definition and case and contact management can be discontinued.
- Confirmatory testing that is negative, and **obtained >24 hours** after a preliminary positive specimen, may represent a true change in case status (positive to negative), or that the preliminary positive was a false positive. Interpretation and subsequent case management should be based on the context of the case, and their clinical and epidemiological situation.
    - Individuals who were **symptomatic at/around the time of initial testing**
        - In general, continue management as a probable case as a change in case status (positive to negative) cannot be excluded,

including continuation of case isolation and contact self-isolation.

- Individuals who were tested as an **asymptomatic contact with high risk exposure** to a case AND remain asymptomatic:
    - If specimen collection was ≤24 hours of the initial preliminary positive, can discontinue public health management as a probable case, including contact self-isolation. However, the individual should continue to self-isolate based on their exposure to a case. Case classification should be updated to 'does not meet' case definition.
    - If specimen collection was >24 hours after initial preliminary positive, in general, case and contact management as a probable case should be continued as a change in case status cannot be ruled out. However, based on the clinical and epidemiological context of the case and their overall pre-test probability, case status could be updated to 'does not meet' case definition based on a negative confirmatory specimen collected >24 hours after the initial preliminary positive specimen.

Interim guidance on the use of the Abbott ID NOW™ instrument and COVID-19 assay

Introduction

This document, prepared October 26, 2020, provides interim guidance on the use of the Abbott ID NOW™ instrument and coronavirus disease 2019 (COVID-19) assay in the context of the Canadian public health system.

The Abbott ID NOW COVID-19 assay is an isothermal nucleic acid amplification technology intended for the qualitative detection of nucleic acid from severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) viral ribonucleic acid (RNA) in direct nasal, nasopharyngeal or throat swabs from individuals who are suspected of COVID-19 by their healthcare provider. While already in widespread use globally, there are several reports of a reduced sensitivity associated with the test when compared with other laboratory-developed tests (LDTs) or commercially available nucleic acid amplification tests (NAAT) such as the Cepheid GeneXpert™ based assay (1). The use of a lower sensitivity test, even a real-time transcription polymerase chain reaction (RT-PCR) method, carries risks to decision-making that can only be offset by the magnitude of possible benefits. It must be understood that a significantly greater degree of diagnostic uncertainty will be introduced/remain with use of the Abbott ID NOW assay, relative to the conventional RT-PCR methods commonly used in Canada at the time of writing. These guidelines will be updated periodically as more information is available regarding test sensitivity in different settings (surveillance, screening, diagnosis) and in the overall context of infection with SARS-CoV-2.

Many of these guidelines may also be applied to other less sensitive molecular and rapid antigen-based tests that may be approved for use in the future.

Key messages

- Health Canada provided approval for use of the Abbott ID NOW COVID-19 assay (October 2020).
- The intended use for this assay as outlined by Health Canada is as follows:
  - The Abbott ID NOW COVID-19 assay performed on the Abbott ID NOW instrument is a rapid molecular *in vitro* diagnostic test utilizing an isothermal nucleic acid amplification technology intended for the qualitative detection of nucleic acid from the SARS-CoV-2 viral RNA in direct nasal, nasopharyngeal or throat swabs from individuals who are suspected of COVID-19 by their healthcare provider within **the first seven days** of the onset of symptoms.
  - Results are for the identification of SARS-CoV-2 RNA. The SARS-CoV-2 RNA is generally detectable in respiratory samples during the acute phase of infection. Positive results are indicative of the presence of SARS-CoV-2 RNA; clinical correlation with patient history and other diagnostic information is necessary to determine patient infection status. Positive results do not rule out bacterial infection or co-infection with other viruses.
  - Negative results should be treated as preliminary and, if inconsistent with clinical signs and symptoms or necessary for patient management, should be tested with different authorized or cleared molecular tests. Negative results do not preclude SARS-CoV-2 infection and should not be used as the sole basis for patient management decisions. Negative results should be considered in the context of a patient's recent exposures, history and the presence of clinical signs and

symptoms consistent with COVID-19.
    - The Abbott ID NOW COVID-19 test is intended for use by medical professionals or trained operators who are proficient in performing tests using the Abbott ID NOW instrument in laboratory and point-of-care (POC) settings.
- The performance of the assay should be verified in the field before recommending its use. This is critical since data obtained from pre-market evaluations cannot account for the variability in training and quality of sample collection that follows use in a broader population. Therefore, clinical performance must continue to be monitored.
- The "in-field" performance characteristics of the Abbott ID NOW is still under evaluation in Canada; however, data about the nature of the technology from other jurisdictions suggest that the tests have lower sensitivity but comparable specificity to other LDTs and commercial NAAT assays. Although, the rapid nature of the assays makes it suitable for POC applications, these performance characteristics, combined with the incidence of infection within the population being tested, must be considered when interpreting the results.
- In discussion with provincial and territorial laboratory directors, the use of this test must be carefully considered.
    - At this time, until further data is collected, because of the decreased sensitivity, all negatives should be considered preliminary negatives.
    - Owing to an expected higher rate of false negatives, it is recognized that reflexive laboratory-based testing of preliminary negatives from the Abbott ID NOW COVID-19 testing depending on its proposed use) will likely introduce an additional burden to reference laboratories already facing enormous testing volumes.
- This document outlines scenarios where the Abbott ID NOW COVID-19 testing may prove useful, should the expected performance characteristics be confirmed.

Current approach to severe acute respiratory syndrome coronavirus 2 testing in Canada

Since the emergence of SARS-CoV-2, testing has been a key pillar of Canada's response to the pandemic. The broad use of testing, as part of an array of public health measures, led to a flattening of the epidemic curve in the spring of 2020, demonstrating the value of testing as a part of the COVID-19 response. To date, testing has relied on molecular (i.e. RT-PCR) testing performed on a nasopharyngeal sample (NP) or alternate respiratory sample collected by a healthcare professional. **This testing method currently remains the gold standard for diagnosing SARS-CoV-2 infection in Canada.**

Considerations for the use of the Abbott ID NOW COVID-19 assay

It is critically important to understand the timing of specimen collection in relation to symptom onset since the sensitivity of the test is not expected to be uniform over the course of infection. Data suggest that viral shedding may begin 2–3 days before the symptoms peak—around the time of symptom onset—and then gradually declines over time thereafter (2,3).

During the first seven days of infection, viral loads are likely to be above the limit of detection for the Abbott ID NOW assay. Although the time of post-symptom onset still needs to be carefully considered. It is also important to understand test performance in relation to the time since a potential exposure when the test is being used for rapid contact tracing (e.g. how many days after exposure might one expect to have viral loads that can be optimally detected using the Abbott ID NOW?).

Notwithstanding the difference in the performance profile, other features of the Abbott ID NOW (including but not limited to; faster turnaround time, lower per-test cost, ability to do the test in a setting by non-professionals on a more frequent basis) suggest that it could have an important role to play in the next phase of the pandemic response.

It is important for public health, microbiology and infectious diseases experts to identify the scenarios where the use of the Abbott ID NOW may further strengthen the public health response by expanding access to testing beyond existing indications and increasing capacity for molecular detection of SARS-CoV-2. Furthermore, establishing mechanisms to allow a new POC test to report into the public health system efficiently is critical (see "Reporting of results and Quality Control" section below).

Balancing test sensitivity against other considerations

The intrinsic performance characteristics of the Abbott ID NOW are not the only factors determining its utility. **The final interpretation of a test must take into account the performance parameters, the prevalence of infection, predictive values and the intended use of the test result.** Therefore, the tolerance for sensitivity and specificity thresholds will vary based on the reason for testing and the expected action that would follow either a positive or a negative result.

In scenarios where critical decisions and actions rely on a test result (e.g. a symptomatic resident in a long-term care home, a patient in an intensive care unit [ICU] who requires immediate treatment), the recommended test would be the most accurate test. At the time of writing, the indicated (best) test would be RT-PCR performed on a NP sample or on a lower respiratory tract sample in patients with evidence of pneumonia. However, there may be circumstances where a rapid POC test can be permissible and enhance testing capacity to support the public health response, particularly when the demand for RT-PCR testing exceeds laboratory capacity or is otherwise unavailable or in situations where a symptomatic individual may otherwise be lost to follow-up.

Clinical situations where infection is prevalent in the community: When the prevalence of infection is high, and the access to RT-PCR testing is unavailable (i.e. northern, remote and isolated [NRI] communities) or when the results are delayed beyond 48 hours because testing demand is exceeding laboratory capacity issues, a POC test may provide an option that will positively impact public health or clinical management. Here the intended use is for early diagnosis of infection. In this situation, a positive result will allow for early implementation of public health measures and contact tracing or clinical management decision-making. Although there will be a need to further evaluate, preliminary data suggests that performance of the Abbott ID NOW in early infection (1–5 days post-symptom onset) may be similar to RT-PCR in terms of sensitivity and performance. However, negative results should be confirmed using conventional NAAT as soon as possible as clinical decisions cannot be made based solely on the Abbott ID NOW test because of the lowered negative predictive value associate with reduced test sensitivity.

Clinical situations where infection is not prevalent in the community and high sensitivity is not the main consideration: There may be alternative settings where a less sensitive test may be acceptable. Although the Abbott ID NOW is currently approved for testing symptomatic individuals within the first seven days of symptom onset, monitoring of asymptomatic individuals who are at risk of introducing infection into high risk settings (e.g. long-term care, correctional facilities) could be considered. Modelling data suggest that testing protocols that incorporate repeated and frequent re-testing of individuals could be effective (4). Here the intended use of a POC test is for monitoring infection in individuals that may not otherwise be able to be tested with the same frequency due to challenges with testing capacity. Due to the potential reduction in pre-test probability of a positive result, the test would need to be confirmed using a laboratory-based NAAT. The purpose of this requirement for confirmation is to reduce the potential for negative factors associated with a false positive test (unnecessary removal from work, stigma that may be associated with infection, etc.).

Proposed use scenarios

At this time, it is not possible to provide an exhaustive list of all cases where the Abbott ID NOW assay might be of benefit. Several scenarios are given as examples below, but are not meant to be proscriptive.

Scenario 1: Northern, remote and isolated settings

The NRI communities face additional barriers to timely test results due to transportation time required to deliver a specimen to a testing laboratory. Given the importance of accurately identifying new cases in NRI communities to prevent spread of SARS-CoV-2 in the face of limited healthcare resources, RT-PCR testing is the recommended test for these settings. While there have been extraordinary efforts to date to bring high quality POC PCR testing to NRI communities (e.g. Cepheid GeneXpert test), significant challenges remain. First and foremost is the ongoing short supply of the GeneXpert COVID-19 test cartridges. The availability of a relatively low complexity POC solution with an anticipated higher test allocation may be an attractive option as a screen-in test to conserve GeneXpert test cartridges for the testing of symptomatic individuals. In this two-test algorithm, if a sample is shown to be positive using the Abbott ID NOW assay, then appropriate actions can quickly be put in place, while negative results can be confirmed on the highly sensitive Cepheid GeneXpert or in a reference laboratory. This may also be useful in other settings where rapid, accurate results are required (e.g. staging for medical procedures in hospitals involving symptomatic patients). This may have additional benefit in allowing the prioritization of GeneXpert test cartridges for NRI communities.

Scenario 2: Early outbreak identification and investigation

While the use of a less sensitive test would not be recommended for the exclusive management of an outbreak, testing of symptomatic individuals and their direct contacts with the Abbott ID NOW assay can be useful for the early identification of possible outbreaks.

- Testing can be done as part of suspected outbreak identification and investigation where patients can be tested rapidly on site if faster preliminary results will help inform and expedite public health action (triage of patients and contact tracing). This may be particularly relevant in situations where a symptomatic individual may otherwise be lost to follow-up.
    - This would always be followed by confirmatory PCR testing, although this requirement could be revisited to determine if ongoing testing is needed.

Scenario 3: Asymptomatic testing in high risk settings

An additional broad category for use of the Abbott ID NOW includes situations that involve the prospective monitoring of asymptomatic individuals for introduction of SARS-CoV-2 into high risk settings. Note that such a proposed monitoring role for non-PCR testing technologies is referred to as "screening" in some other documents on COVID-19 testing strategies. At this time, the market authorization for the Abbott ID NOW from Health Canada—Medical Devices Bureau is focused on symptomatic testing in the early phase of disease, so the use of this test in a monitoring context will require clinical validation. The frequency of repeat testing is not yet defined (see below).

- Repeated testing of workers in congregated settings to prevent introduction or to minimize the chance of spread within a site, including:
  - Large processing plants
  - Long-term care facilities
  - Homeless shelters
  - Farm/migrant workers
  - Inmates in correctional facilities
- The Abbott ID NOW could be used for prospective testing of low-risk, asymptomatic visitors and staff entering congregated settings.
- Important additional considerations for the use of Abbott ID NOW include the following:
  - Testing would always need to be done in the context of PCR confirmatory testing of all positive cases
  - Reflexive PCR testing of preliminary negative cases needs to be carefully considered and is not being recommended at this time due to the significant impact it would have on current testing capacity in laboratories already facing enormous testing volumes
  - The frequency of repeat testing will need to be carefully examined to ensure the testing strategy can correctly identify individuals during a high viral period early in infection
  - The use of alternative specimen collection (rather than with oral or nasal swabs included with the Abbott ID NOW) may be more acceptable for collecting samples from asymptomatic individuals than NPs

These situations represent scenarios where frequent entries and exits multiply the potential introduction of the virus into high risk settings known to facilitate the rapid spread of infection. It is not yet possible to articulate the implementation approach that best supports the public health goals of testing (case identification, isolation contact tracing, etc.). It is clear that a false negative test can occur early in infection even with the most sensitive RT-PCR methods. As such, repeat testing may be necessary to detect infection in cases with high clinical suspicion of disease. The Abbott ID NOW assay may offer ease of use, the ability to conduct testing outside traditional laboratory settings and rapid time to results to enable frequent testing and offset the reduced sensitivity.

Approach to the potential use of the Abbott ID NOW assay

How the results from the Abbott ID NOW assay are interpreted and how it impacts public health and clinical management of patients need to be considered. To do this, it is critical that end users understand the prevalence of infection in the population they are testing. This necessitates a robust surveillance system that communicates regularly with the end users.

Positive result

Positive results should be considered "preliminary positive" until confirmed using a reference RT-PCR method. While the Abbott ID NOW assay is expected to have high specificity, false positives can be expected, particularly if the prevalence of infection in the population tested is low, thus decreasing the pre-test probability of the assay. All patients with a positive result will require isolation. If the confirmatory RT-PCR is negative, discontinuation of isolation can be considered depending on the clinical context that generated the initial test.

Negative result

In interpretation of a negative Abbott ID NOW result, the clinical context of the test (asymptomatic versus symptomatic) and the pre-test probability of infection must be considered. In patients where the pre-test probability of COVID-19 remains high (e.g. known contact, high community transmission), then the individual should undergo confirmatory testing using RT-PCR to direct further management. If the pre-test probability is low, then the individual can be monitored in the absence of isolation and reference testing.

Frequency of testing

As highlighted above, the Abbott ID NOW assay is ideally used in surveillance/screening programs where individuals get repeat tests to account for a lack in sensitivity. If the Abbott ID NOW is used in a monitoring approach, the ideal frequency of testing remains to be defined. The effectiveness of this strategy is dependent upon several associated factors, including the proportion of asymptomatic infections, the sensitivity of the assay and the time to results (assuming that self-isolation would occur once a positive test is identified).

Reporting of results and quality assurance

The use of the Abbott ID NOW will most likely occur outside of a laboratory environment. The current anticipated market authorizations are expected to require oversight of the testing

procedure by a trained healthcare professional, at least in the short term. It will be essential that a mechanism for reporting of results into the public health system and/or laboratory system be developed to ensure appropriate data capture and quality control, and to support public health action.

It is critical that quality assurance practices be considered when implementing POC testing, regardless of the perceived simplicity of the test. Where POC testing is implemented outside a hospital environment, sites are recommended to partner with local accredited laboratories for ongoing guidance and oversight. The laboratory director and partnering laboratories will guide sites to ensure important quality assurance practices are in-place.

Examples of quality assurance practices that must be considered:

- Training and ongoing authorization of staff who will perform POC testing
- Initial and ongoing reagent validation prior to clinical use
- Quality control practices for regular monitoring of test performance
- Proficiency testing to monitor overall testing practices at a site
- Troubleshooting issues with tests and/or devices
- Reporting of results

Critical scientific questions

The science continues to evolve daily as unprecedented global investment in research and development continues. Despite this, several critical questions remain to inform the use of new tests such as the Abbott ID NOW and sample types.

- How do these tests perform in "real life"?
  - Most submissions for approval have used simulated samples to evaluate the tests. This creates uncertainty about the true performance when applied to patients. There must be a verification of performance by comparing the real-life performance of intended use in the field compared with the traditional nucleic acid amplification methodology.
- How frequently is testing required to close the sensitivity gap?
  - This requires understanding of the dynamics of the test over time. It will be important to determine the frequency of testing to best mitigate the risk of cases being missed due to the lower sensitivity of the Abbott ID NOW.
  - At what threshold of community transmission is repeat testing in specific environments beneficial?
- How do lower sensitivity tests and lower sensitivity sample types interact?
  - If the NP swab is considered the gold standard, then what is the impact on sensitivity of using a less sensitive specimen for testing? How do the assays compare when an oral or nasal swab or alternative sample type such as a saline gargle is used?
  - If oral and/or nasal swabs are used as an alternative to the NP swab, the impact must be evaluated to inform potential for use.

How long are people with COVID-19 infectious?

Source: Emerging Sciences Group of the Public Health Agency of Canada. Emerging Evidence on COVID-19: Rapid Review of Infectious Period. September update. Full report available from: phac.emergingsciencesecretariat-secretariatdessciencesemergentes.aspc@canada.ca

Background: COVID-19 cases need to be isolated long enough to prevent further transmission but no longer than needed. Determining the infectious period of COVID-19 is complicated by four factors: 1) people can be diagnosed when they are symptomatic, pre-symptomatic or asymptomatic, 2) the common diagnostic test, RT-PCR, is accurate for diagnosis as it is able to detect viral genetic material, but it cannot document when someone is no longer infectious because it cannot distinguish whether viral particles are still infectious or not, 3) cell culture is the best way to confirm whether infectious virus is present, but it takes time and requires specialized laboratory facilities, and 4) although transmission is primarily respiratory, virus has been found in feces and eye secretions.

Methods: Twenty databases and key websites were searched for relevant reviews, peer-reviewed publications and preprints up to August 31, 2020. Keywords included: "Shedding", "Viral dynamics", "Viral clearance", "Viable", "Culture", "Infectivity", "SARS-CoV-2 detection", "Infectious Period", "Communicability period", "Recurrence", and "Re-positive". Data from studies were extracted into evidence tables on risk of infection, severity of disease and mortality and organized by asymptomatic, pre-symptomatic, symptomatic, recurrent or reinfection, as well as culture versus RT-PCR and sample source (e.g. respiratory, fecal, etc.).

Results: Over 1,000 citations were screened and relevant full texts were reviewed. There were some good quality prospective cohort studies, but the majority of publications were case reports and observational studies of contact tracing; many of these were preprints and are at high risk of bias. Due to their number and preliminary nature, not all case reports were summarized.

Symptomatic infectious period, N=107 studies

CULTURE (that measures viable virus): N=18 studies and two systematic reviews:

- Respiratory
  - Mild illness: Cultures from respiratory samples—taken from the time of self-reported symptom onset—have documented viral shedding for 8–10 days with a peak in viral load ranging from just before to during the first week after onset of illness.
  - Severe illness: Culture from respiratory samples have documented cases of prolonged viable viral shedding (18–32 days). These cases are typically individuals who are either immunocompromised or have multiple chronic underlying health conditions. These studies usually include single cases or small sample sizes and many are still in preprints.
  - Feces: SARS-CoV-2 has been cultured from the fecal/rectal samples of confirmed cases, however the length of viable virus shedding and whether it is a potential transmission route remains unclear.

RT-PCR (that measures viral RNA): N=88 studies and six systematic reviews:

- Nasopharyngeal swabs: Most studies show RT-PCR tests become negative within 14–20 days of self-reported symptom onset.
  - Prolonged viral RNA shedding (up to 83 days) have been reported. Multiple studies have found this is positively associated with severity of COVID-19 and older age. Once these cases have clinically recovered, cultures have not detected viable virus and there has been no evidence of transmission.
- Stool samples: Stool samples can remain positive a few days to four weeks longer than respiratory samples.
- Eye swabs: SARS-CoV-2 RNA has been identified in the eye up to 22 days post onset of self-reported symptoms.

Pre-symptomatic infectious period, N=25 studies

- CULTURE: Viable virus has been cultured from respiratory samples 1–6 days prior to symptom onset and from the rectum as early as three days before symptom onset.
- RT-PCR has detected COVID-19 virus RNA from respiratory samples 1–7 days (2.5 days on average) before symptom onset.

Asymptomatic infectious period, N=25 studies

- CULTURE and RT-PCR: Viable virus and viral RNA was highest during the first week of infection and declined in subsequent weeks. Based on the current evidence, the total infectious period of asymptomatic cases appears to be similar to, or shorter than, mildly symptomatic cases; viral loads have been similar.

Recurrent viral shedding in convalescent period, N=55 studies

- CULTURE and RT-PCR: Only one culture study found viable virus in a recurrent case. Multiple case reports and observational RT-PCR studies have detected recurrent viral RNA shedding in people who were asymptomatic in the convalescent period, typically within seven days of two consecutive negative RT-PCR results. Following recurrence, patients remained viral RNA positive for approximately 1–8 days, but no evidence of transmission was reported.

Reinfection, N=2 studies

- Two studies have been published with compelling evidence that reinfection can occur. In both cases genetic analysis confirmed the virus from the first and second infection were different. This appears to be rare.

Conclusion: Across studies, similar viral loads have been reported for asymptomatic, pre-symptomatic, and symptomatic cases. Mild cases are typically no longer infectious 10 days after diagnosis. More severe cases are generally infectious for at least 20 days; when these cases are no longer infectious can only be confirmed by viral culture.

Cell-based culture of SARS-CoV-2 informs infectivity and safe de-isolation assessments during COVID-19

ABSTRACT

Background

The detection of SARS-CoV-2 RNA by real-time polymerase chain reaction (PCR) in respiratory samples collected from persons recovered from COVID-19 does not necessarily indicate shedding of infective virions. By contrast, the isolation of SARS-CoV-2 using cell-based culture likely indicates infectivity, but there are limited data on the correlation between SARS-CoV-2 culture and PCR.

Methods

One hundred and ninety-five patients with varying severity of COVID-19 were tested (outpatients [n=178]), inpatients [n=12] and critically unwell patients admitted to the intensive care unit [ICU; n=5]). SARS-CoV-2 PCR positive samples were cultured in Vero C1008 cells and inspected daily for cytopathic effect (CPE). SARS-CoV-2-induced CPE was confirmed by PCR of culture supernatant. Where no CPE was observed, PCR was performed on day four to confirm absence of virus replication. Cycle threshold (Ct) of the day four PCR ($Ct_{culture}$) and the PCR of the original clinical sample (Ct_{sample}) were compared, and positive cultures were defined where Ct_{sample} - $Ct_{culture}$ was $\geq$3.

Findings

Of 234 samples collected, 228 (97%) were from the upper respiratory tract. SARS-CoV-2 was only successfully isolated from samples with Ct_{sample} $\leq$32, including in 28/181 (15%), 19/42 (45%) and 9/11 samples (82%) collected from outpatients, inpatients, and ICU patients, respectively. The mean duration from symptom onset to culture positivity was 4.5 days (range 0-18). SARS-CoV-2 was significantly more likely to be isolated from samples collected from inpatients (p<0·001) and ICU patients (p<0·0001) compared with outpatients respectively, and in samples with lower Ct_{sample}.

Conclusion

SARS-CoV-2 culture may be used as a surrogate marker for infectivity and inform de-isolation protocols.

Keywords: COVID-19; SARS-CoV-2; viral culture; infection control; de-isolation

Introduction

In late December 2019, a cluster of pneumonia cases of unknown etiology were reported in Hubei Province, China [1]. The causative agent, a novel betacoronavirus, now known as SARS-CoV-2, was isolated on January 7, 2020 [2] and the genetic sequence January 10, 2020 enabling the rapid development of diagnostic assays for COVID-19 (the disease caused by SARS-CoV-2) to be available within a month of the outbreak's notification to the World Health Organization (WHO) [3]. Effective control of SARS-CoV-2 transmission requires widespread testing, isolation, contact tracing of infected persons and other non-pharmaceutical interventions [4], particularly in the absence of effective SARS-CoV-2-specific antivirals and vaccines. Nucleic acid testing such as real-time reverse transcriptase polymerase chain reaction (PCR) is the predominant diagnostic method to confirm infection, however, the detection of SARS-CoV-2 RNA may not always indicate the presence or shedding of viable virus with replicative capacity and, by implication, transmissibility [5]. The diagnostic value of culture in the routine management of COVID-19 is limited by requirements of isolation to be performed under physical containment laboratory level 3 (PC3) biosafety conditions [6], technical expertise, turnaround times (TATs), and costs. However, the ability to culture SARS-CoV-2 has important roles in providing adequate positive control material for the development, validation, evaluation and quality assurance of SARS-CoV-2 diagnostic assays; supporting the development of vaccines and therapeutic agents, and enabling research into viral virulence and transmission.

Despite clinical recovery, there are a proportion of patients where SARS-CoV-2 RNA remains detectable for many days to weeks [5]. The relationship between persistent PCR positivity and virus viability is important in understanding the natural history and pathogenesis of SARS-CoV-2 infection, and whether truly persistent infection occurs. This has significant implications for the release of infected persons from quarantine, particularly for those who reside in high-risk settings such as aged care, mental health and correctional facilities, or work with at-risk population groups such as

healthcare workers (HCWs). Persistent SARS-CoV-2 RNA detection also has implications for patient isolation and bed management, the safe use of non-invasive ventilation and ongoing requirements for appropriate use of personal protective equipment for HCWs when caring for such patients.

We investigated the correlation between SARS-CoV-2 culture and PCR results from respiratory tract samples collected from persons with COVID-19 to guide the safe de-isolation of those with persistently positive PCRs.

Methods

SARS-CoV-2 PCR and cell culture results of respiratory tract samples received between March 1 and April 22, 2020 were analysed. Samples were inoculated into cell culture as part of (i) routine laboratory protocol at the start of the epidemic; (ii) if collected from patients admitted to the ICU and (iii) if requested by attending physicians (usually due to persistent PCR positivity in an individual awaiting release from quarantine) or public health physicians as part of outbreak investigations.

Sample types

Samples were collected from the upper respiratory tract (URT; nasopharyngeal swabs and combined nose and throat swabs) and lower respiratory tract (LRT; sputum, endotracheal aspirate, non-bronchoscopic bronchoalveolar lavage). URT swabs were received in 1-3 mL of viral or universal transport media (UTM), Amies transport media, or dry; stored at +4°C and tested within 12 hours of specimen receipt.

SARS-CoV-2 nucleic acid detection

RNA was extracted from 200µL of respiratory tract samples using the MagNA Pure 96 instrument's Viral NA Small Volume Kit (Roche Diagnostics GmbH, Mannheim, Germany) following the "Pathogen Universal Protocol" (elution volume, 100µL) according to the manufacturers' instructions. SARS-CoV-2 nucleic acid amplification and detection were performed using the LightCycler® 480 II System

Accepted Manuscript

(Roche Diagnostics, Rotkreuz, Switzerland). The primers and probes, mastermix composition and cycling conditions used are outlined in (Table 2, Supplementary). Each PCR assay included a negative (RNAse-free water), positive (10^{-3} dilution of a SARS-CoV-2-positive cell culture supernatant) and internal control (human beta-globin gene). Cycle threshold (Ct) of positive samples were recorded.

SARS-CoV-2 gene targets included E, RdRp, N, M, and ORF1ab for samples from ICU patients; and between one and four of E, RdRp, N and ORF1ab for all other samples. Global shortages of reagents and consumables influenced the targets tested. The total number of samples tested per target were: one (n=24), two (n=115), three (n=22), four (n=62) and five targets (n=11).

SARS-CoV-2 culture of respiratory tract samples

Samples with detectable SARS-CoV-2 RNA were inoculated into cell culture under PC3 conditions [4] on the same day or stored at +4°C for inoculation the following day. Vero C1008 (Vero 76, clone E6, Vero E6 [ECACC 85020206]) cells were seeded at 1-3 x 10^4 cells/cm^2 with Dulbecco's minimal essential medium (DMEM; LONZA, Alpharetta, GA, USA) supplemented with 9% foetal bovine serum (FBS; HyClone™, Cytiva, Sydney, Australia) in 25cm^2 cell culture flasks or Costar® 24-well clear TC-treated multiple well plates (Corning®, Corning, NY, USA). The medium was changed within 12 hours for DMEM containing 1% FBS with the addition of penicillin, streptomycin and amphotericin B deoxycholate to prevent microbial overgrowth and then inoculated with 500µL (cell culture flasks) or 200µL (24-well plates) of clinical sample. Plates were sealed with AeraSeal™ Film (Excel Scientific, Inc., Victorville, CA, USA) to minimize evaporation, spillage, and well-to-well cross-contamination. Inoculated cultures were incubated at 37^0C in 5% CO_2 for 5 days (day 0 to 4) and observed daily for CPE, 200µL of viral culture supernatant was collected on days 1, 2, 3 and 4 for the ICU cohort and on day 4 for all other samples.

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

Where CPE was observed (generally within 2-3 days post-inoculation), SARS-CoV-2 replication was confirmed by PCR. Terminal sampling and PCR testing of culture supernatant was performed on day 4 as CPE may not be observed despite active viral replication, as seen with SARS-CoV [7]. Day 4 was chosen for terminal sampling as this was the optimal time for reading the endpoint as determined by the 50% tissue culture infective dose ($TCID_{50}$) assay below. Additionally, with no medium change and using a concentration of amphotericin B (2.5µg/mL), cell monolayer breakdown was observed from day 5 onwards in some cultures.

SARS-CoV-2 nucleic acid detection in cell culture supernatant

SARS-CoV-2 RNA was extracted from 200µL of culture supernatant using the EZ1 Advanced XL platform and EZ1 Virus Mini Kit v2.0 (Qiagen, Valencia, CA, USA) according to the manufacturers' instructions. SARS-CoV-2 PCR was then performed as above.

Determination of $TCID_{50}$

A primary isolate, SARS-CoV-2/01/Human/NSW Australia|EPI_ISL_407893|2020-01-24 (GISAID), was titrated in serial one log dilutions (from 10^{-1} to 10^{-8}) to obtain a $TCID_{50}$ using 24-well culture plates of Vero C1008 cells. The plates were observed daily for CPE using an inverted optical microscope for five days, and wells were considered positive if any characteristic altered cell foci were seen (Figure 4, Supplementary). The end-point titres were calculated according to the Reed and Muench method [8] based on four replicates for titration, and the infectious virus titre of our SARS-CoV-2 stock was 1 x $10^{6.5}$ infectious particles per 200µL (Figure 1).

Determination of virus replication and Ct cut-off for virus viability in cell culture supernatant

To clarify the significance of the Ct of culture supernatant in the absence of CPE, a dilutional series of virus stock was run (as per $TCID_{50}$) and SARS-CoV-2 RNA detection by PCR targeting six genes (E, RdRp, M, N, ORF1ab and ORF1b) at each dilution was performed (Figure 1). This allowed the limit of detection (LoD) of viral culture $TCID_{50}$ to be compared to the LoD of the various PCR gene targets

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

and demonstrated that the highest Ct reflective of non-viable virus was 37·29 with the ORF1b gene target. Using the same targets, the dilution series indicated a change in 1 log dilution of virus concentration correlated with a change in Ct of approximately ±3. This was also confirmed when testing synthetic plasmids using real-time quantitative PCR assays demonstrated that a 1 log difference in viral load corresponded to a change in Ct of 3·44 ± 0.16. Furthermore, a Ct of 34 and 37 correlated with viral loads of approximately 100 copies/mL and 10 copies/mL, respectively, a difference of 1 log (data not shown).

Positive viral cultures were defined as (i) CPE visualized and SARS-CoV-2 RNA detected from culture supernatant, or (ii) no CPE visualized but a decrease between the Ct of the original sample (Ct_{sample}) and day 4's terminal culture supernatant ($Ct_{culture}$) of ≥3 (equivalent to a 1 log increase in virus quantity), i.e. Ct_{sample} - $Ct_{culture}$ ≥3 = culture positive. Conversely, negative viral cultures were defined as (i) CPE not visualised, and no SARS-CoV-2 RNA detected from the culture supernatant, or (ii) no CPE visualized in culture and Ct_{sample} - $Ct_{culture}$ <3. Where SARS-CoV-2 RNA was detected in terminal sampling, we surmise that Ct_{sample} - $Ct_{culture}$ <3 was due to residual inoculated clinical sample and not replicating virus. This is supported by the initial rise in $Ct_{culture}$ on day 1 compared to Ct_{sample} on day 0 (Figure 2). In addition, no viral replication was identified with blind passaging of the first 20 cultures without CPE and Ct_{sample} - $Ct_{culture}$ <3, indicating the absence of viable virus. By contrast, SARS-CoV-2 replication was demonstrated by CPE and detectable RNA in subsequent passaging of samples without initial CPE but where Ct_{sample} - $Ct_{culture}$ was ≥3.

Statistical analyses

Welch's t-test, two-tailed hypothesis with 95% confidence intervals (95% CI) was used to compare the mean Ct of URT and LRT samples (Figure 6, Supplementary) of culture positive (with or without CPE) and culture negative samples (Figure 5, Supplementary), and to determine the mean Ct of the N gene in each week of culture (Figure 3). Fisher's exact test was used to determine significance in

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

culture positivity rates between different cohorts with 95% CI, (Table 1) and the difference between the culture positive samples per week (Figure 3). Mann-Whitney U test, two-tailed hypothesis (95% CI) was used to compare the date of symptom onset in culture positive and negative patients (Figure 7, Supplementary) and to compare the median Ct of the N gene in each week (Figure 3). *p*-values <0·05 were considered statistically significant.

Results

Of 234 samples (228 [97%] from the URT) collected from 195 persons with COVID-19, 11 (5%), 42 (18%) and 181 (77%) were from 178 outpatients, 12 inpatients not requiring ICU and five ICU patients, respectively (Table 1). SARS-CoV-2 was isolated from 56 (24%) samples, with CPE observed and SARS-CoV-2 RNA detected in 46 (20%) samples. No CPE was observed in 10 (4%) samples but fulfilled the Ct_{sample} - $Ct_{culture}$ ≥3 criteria to define positivity. Whole genome sequencing failed to identify specific SARS-CoV-2 lineages A (A, A.1-A.5) or B (B, B.1-B.9 and B.11) where CPE was absent [9]; furthermore the samples were not collected from any epidemiologically linked clusters (data not shown). Mean Ct of the N gene were significantly lower in CPE positive cultures when compared to both CPE negative but PCR positive cultures (25·01 vs 27·75, *p* <0·001) and negative cultures (25·01 vs 36·87, *p* <0·001) (Figure 5, Supplementary).

The highest Ct for the N gene target in any clinical sample where SARS-COV-2 was successfully cultured was 32. Based on this result and the Ct cut-off value of 37 determined by PCR of $TCID_{50}$ dilutions, and incorporating a 1 log margin of error, we were confident that any clinical sample with a Ct of ≥37 was not indicative of viable virus (Figure 1). SARS-CoV-2 was significantly more likely to be isolated in inpatients compared to outpatients (45% vs 15%, *p*<0·001), and ICU compared with other inpatients (82% vs 45%, *p*=0·04) or outpatients (82% vs 15%, *p*<0·001) (Table 1). Serial sampling of ICU patients and testing multiple gene targets demonstrated the variability in Ct when SARS-CoV-2 RNA was detected, with the E gene generally giving the lowest Ct and N gene the

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

highest (Figure 2 and Figure 6, Supplementary) in this cohort. There was consistent correlation over time between targets and concordance with the selected definition for culture positivity (Figure 2).

Of note, SARS-CoV-2 was isolated 17 and 18 days post-symptom onset in a 36 year old female patient with hypothyroidism; no other samples were culture-positive beyond 10 days after symptom onset (Figure 3). The mean Ct across all cultures increased as time from symptom onset increased (Figure 3). Using the N gene as a representative target, cultures were significantly more likely to be positive from samples collected within the first week after symptom onset compared to the second week (80% vs 45%, p=0·002), and between the second and third week (45% vs 4%, p<0·001) (Figure 3).

Ct values of the most frequently used target (N gene) ranged from 17·56 to 40, mean=34·16, IQR (29·21 –39·37). Mean Ct of the N gene was significantly lower in LRT compared with URT samples (26·76 vs 34·41, p<0·001) (Figure 6, Supplementary). No significant difference was observed for the other targets, potentially due to a type II error.

In clinical samples where SARS-CoV-2 was isolated, the mean duration between symptom onset and sample collection was 4·5 days (median 3·5, range 0-18). By contrast, the mean duration between symptom onset and sample collection in culture negative samples was 20 days (median 18·4, range 3-29; p<0·001) (Figure 7, Supplementary).

Discussion

Detection of SARS-CoV-2 RNA by PCR has been the primary diagnostic method to confirm COVID-19. As an indicator of infectivity, the absence of detectable SARS-CoV-2 RNA in respiratory tract samples is utilized in many jurisdictions as a requirement for release of persons with COVID-19 from quarantine [10]. In Australia, infected persons from high-risk settings (including but not limited to HCWs) are required to have two consecutive negative SARS-CoV-2 tests at least 24 hours apart

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

before being allowed to return to such settings [11]. Whilst there are reports of persistent or prolonged PCR positive results in recovered persons [12,13], few have provided robust data to support that they are no longer infectious. Furthermore, there is substantial variability in the duration of PCR positivity (up to 28 days after symptom onset) [12], resulting in individuals (including HCWs) being isolated for prolonged periods given the potential risks of virus transmission. As the detection of SARS-CoV-2 RNA in respiratory samples does not necessarily indicate viable infectious virions, we examined the correlation between the Ct of PCR positive samples and viral culture, a surrogate marker for infectivity. The Australian National Guidelines for Public Health Units also recommends that viral culture results be considered when deciding on the release of persons from quarantine following COVID-19 [11].

We successfully isolated SARS-CoV-2 from upper and lower respiratory tract samples collected from persons with acute COVID-19 and correlated the yield of cell culture with PCR Ct values. Similar to other reports [14,15] we demonstrate that the threshold Ct where culture will be successful is <32 for the N gene target. However, this Ct is specific for our laboratory and we would recommend that diagnostic laboratories correlate their Ct values with culture results due to the variable analytical performance between different SARS-CoV-2 PCR assays [16,17].

The cell culture method described herein relies not only on detection of CPE but incorporates PCR testing into the workflow. We demonstrate that virus with replicative capacity can be isolated and detected despite the absence of CPE by correlating the Ct of cell culture supernatant with the Ct of the original clinical samples where SARS-CoV-2 was detected. This effect was not due to any SARS-CoV-2 genotypes, however further genetic analysis may be warranted. This provides a more objective and sensitive measure of virus isolation as the detection of CPE can be subtle or absent due to low levels of virus that result in a delayed rise in virus load beyond day four in the cell lines used. This may assist in improving workflows in laboratories processing large numbers of cell

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

cultures or those with reduced capacity to detect CPE. A Ct_{sample} cut-off >32 in our laboratory correlates with non-viable virus; and in the absence of CPE, a Ct_{sample} - $Ct_{culture}$ value <3 also indicates an absence of viral replication, suggesting these individuals could be safely released from isolation.

We have demonstrated that culture yield is improved when samples are collected as close to the date of symptom onset as possible, and that virus isolation is more likely in patients with more severe illness requiring admission to hospital or the ICU compared to outpatients. A previous study determined that virus may be isolated up to six days prior to symptom onset [18], however our study did not include such a cohort. Given the TATs , culture results of samples collected from persons during the pre-symptomatic stage would not be available in a meaningful timeframe to guide clinical management but would provide laboratory evidence of pre-symptomatic or asymptomatic SARS-CoV-2 transmission. We showed culture positivity out to 18 days post-symptom onset in one patient, which is ten days longer than previous findings from Singapore [15]. As paired URT and LRT samples were not collected concurrently in this study, we were not able to ascertain the relationship between the two in the context of de-isolation assessments. In the majority of persons that have clinically recovered from COVID-19, LRT samples may not be available, particularly in the absence of sputum production.

We did not assess whether SARS-CoV-2 replication in the absence of CPE occurs in cell lines other than Vero C1008 cells, However, this has been described in MEK and COS cell lines during the isolation of SARS-CoV [7]. The culture-positive samples demonstrating no CPE but detectable virus replication by PCR were predominantly seen in the ICU cohort with approximately half collected from the LRT. Given the small sample size we were unable to determine whether other factors (e.g. concurrent infections, antimicrobial use) may have affected detection of CPE in these samples. Due to the limited volume of clinical sample received, culture was not set up in duplicate however quality

Accepted Manuscript

Downloaded from https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1579/5937368 by guest on 19 March 2021

control to ensure the sensitivity of the cells was undertaken with a stock of titred virus to ensure a consistent LoD was maintained.

The performance of our inhouse SARS-CoV-2 assay was comparable to the Roche cobas® SARS-CoV-2 (Roche Diagnostics, Rotkreuz, Switzerland), (data not shown). Due to reagent shortages, not all samples or culture supernatants were able to be tested with all five SARS-CoV-2 gene targets (E, RdRp, M, N and ORF1ab). Nevertheless, we hypothesize that the findings using the N target would be similar for the other targets as a similar pattern was observed where testing of multiple targets were performed (Figure 2). Nucleic acid extraction from the primary sample and culture supernatant was performed on the MagNA Pure 96 and EZ1 Advanced XL instruments, respectively. Previous evaluations of automated nucleic acid extraction instruments for non-SARS-CoV-2 respiratory viruses showed superiority of the EZ1 Advanced XL compared to the MagNA Pure 96 [19], but there are limited data on the performance of extraction instruments for SARS-CoV-2. We were unable to ascertain if different swab types or UTM affected either PCR or culture results. This study also did not investigate why certain individuals shed SARS-CoV-2 RNA for longer periods compared to others, nor were we able to determine whether there were any factors such as immunosuppression that may have explained prolonged viral shedding, and further research is recommended to address these questions.

In summary, viral culture may assist clinicians to release from isolation individuals who have recovered clinically but remain persistently or intermittently positive SARS-CoV-2 by PCR. Whilst there is limited availability of cell culture in most clinical diagnostic laboratories, this capacity adds important insights not provided by molecular methods and should be maintained in reference laboratories to guide clinical management and de-isolation.

Acknowledgments

We thank Jimmy Ng[1] and Basel Suliman[1] for their assistance with inactivation of cell culture supernatant and nucleic acid extraction. Clinical specimens were received and processed at the NSW Health Pathology-Institute of Clinical Pathology and Medical Research (NSWHP-ICPMR) laboratory for standard of care diagnostic purposes and deemed not research. A non-research determination for this project was granted by the Health Protection NSW as it was a designated communicable disease control activity.

Abstract: Background. The highly variable manifestation of the COVID-19 disease, from completely asymptomatic to fatal, is both a clinical and a public health issue. The criteria for discharge of hospitalized patients have been based so far on the negative result of Real-Time Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) tests, but the persistence of viral fragments may exceed that of the integral virus by weeks. The aim of our study was to verify the clearance of the virus at viral culture in patients hospitalized for COVID-19 that have clinically recovered but are still positive on nasopharyngeal swab. Methods. The study was conducted in hospitalized patients with positive RT-PCR on nasopharyngeal swab. Patients included were from asymptomatic to severe cases and performed nasopharyngeal control swabbing on day 14 for asymptomatic patient or at least three days after remission of symptoms. RT-PCR positive specimens were sent to a biosafety level 3 laboratory for viral culture. Results. We performed a combined analysis of RT-PCR and a highly sensitive in vitro culture from 84 samples of hospitalized patients. The average age was 46 ± 20.29, and 40.5% of the subjects had radiologically confirmed pneumonia, with average PaO_2 of 72.35 ± 12.12and P/F ratio of 315 ± 83.15. Ct values for the N gene were lower in the first swab than in the control one ($p < 0.001$). The samples from 83 patients were negative at viral culture, and RT-PCR on the respective supernatants always confirmed the absence of viral growth. Conclusions. Our preliminary results demonstrate that patients clinically recovered for at least three days show the viral clearance at viral culture, and presumably they continued to not be contagious.

1. Introduction

Since the outbreak of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic, the increase in the number of cases that have reported positive to diagnostic tests has increased the impact on healthcare and on global public costs. In several areas, the rise in the absolute number of people tested positive to SARS-CoV-2 has been correlated to a higher number of tests performed in the general population, in accordance with improved contact tracing. As a higher transmission in younger subjects has been observed, as compared to the earlier phases of the pandemic, in the current wave, we are able to directly keep track of a greater number of mild and asymptomatic cases [1].

Studies have shown a wide variability in the sensitivity of Real-Time Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) protocols for the detection of SARS-CoV-2, with a false negative rate ranging from 2% (95% CI, 0.3 to 7.9%) to 39.8% (95% CI, 30.2 to 50.2). This variability seems to be at least partially related to the difference in the reagents (i.e., primer sets, buffers, and enzymes, and laboratory kit components in general) that are used [2], but also to the sample type/location, operator, and sample storage time/temperature, as well as the nucleic acid extraction method used [3].

A crucial point in the management of coronavirus disease 2019 (COVID-19), at patient as well as at population level, is to define the exact kinetics of viral shedding and infectiousness. Little is known about the minimal viral load needed to trigger a state of disease, be it completely asymptomatic or overt COVID-19. Furthermore, we currently do not know the clinical meaning of the detection of a certain level of the virus with current diagnostic molecular tests in a general individual, i.e., whether he or she is a potential carrier and what the odds are that they could be, as well as the probability of them developing an overt syndrome. Conversely, to date, detecting positivity to a test for SARS-CoV-2 in a patient with overt disease does not give clear information about how much he or she is actually contagious. A clear frame could shed new light on the kinetics of the viral replication in each host, and possibly give information about why and how some individuals remain completely asymptomatic while others develop a fatal disease. Most importantly, understanding viral dynamics would have a clear impact on the management of COVID-19 at a population level, as it would form the basis of optimized individual isolation timing and social distancing as well as discharge criteria from the hospital.

In addition, many cases have been described of subjects who remain positive to the RT-PCR on nasopharyngeal swab, even many days after the onset of the disease, despite no longer having symptoms. More interestingly, it is not infrequent that patients who have been discharged with repeatedly negative RT-PCR results show again (weakly) positive RT-PCR results at random control swabs, raising concern about the possible need of again establishing isolation measures to avoid the risk of infection transmission from these subjects who have a "viral clearance" from the respiratory system.

Only a few studies, though, have investigated the correlation between RT-PCR cycle thresholds (Ct) and the actual cultivability of the virus from the same samples in vitro.

The aim of our study is to verify, through viral culture, the true persistence of the active, and therefore potentially infecting, virus during the follow-up of patients affected by COVID-19 when they are clinically recovered, including in the analysis of the correlation between Ct cycles and cultivability of virus in vitro patients showing a broad spectrum of clinical severity, i.e., from asymptomatic to severely ill.

2. Methods

This study was conducted in patients hospitalized from 1 August to 30 September 2020 in the Respiratory Diseases and Infectious Diseases Units at the University Hospital "Policlinico Riuniti" in Foggia, Italy. Upon entering the emergency room (ER), chest X-ray, laboratory tests, blood gas analysis, and nasopharyngeal swab for SARS-CoV-2 were performed. Patients were admitted to our ward after a positive RT-PCR result on nasopharyngeal swab (T0).

During the hospital stay they underwent standard care medication (corticosteroids, enoxaparin, mucolytics and antibiotics) and oxygen or non-invasive ventilation, according to their clinical condition.

A nasopharyngeal control swab was performed on day 14 if the patient was completely asymptomatic or at least three days after remission of symptoms (T1) and therefore declared "clinically recovered". This definition includes complete weaning from oxygen therapy or ventilator support and no main symptoms of infection (no fever, no dyspnea, SaO_2 stably above 96% in room air), with laboratory values compatible with only iatrogenic effect (e.g., mild leukocytosis from corticosteroids) and mild elevation of D-dimers, though nonetheless highly reduced from the time of admission. In this case, patients could be discharged from hospital if he or she was negative at nasal swab.

This schedule is based on the national discharge guidelines that needed a negative result of RT-PCR performed on nasopharyngeal swabs on two consecutive days. It is also based on a highly improbable negative RT-PCR in the first 14 days of hospital stay. We further investigated four clinically recovered patients who were persistently positive, requiring more than 1 month of hospitalization. In the case of positive RT-PCR, the nasopharyngeal swabs were sent to a biosafety level 3 (BSL-3) laboratory for viral culture.

This study was approved by our Institutional Review Board (Dir 389-20). All patients' data were collected in the context of routine clinical care, and written informed consent was signed at admission according to hospital policy.

2.1. Specimen Processing and Analysis

2.1.1. RT-PCR

Viral RiboNucleic Acid (RNA) was extracted from nasopharyngeal swabs within 2 h of collection, using the STARMag 96 × 4 Universal Cartridge kit with the Microlab NIMBUS IVD instrument, according to the manufacturer's instructions (Seegene Inc. Seoul, Korea). Amplification and detection of target genes (N, E, and RdRP) was performed using the commercially available kit AllplexTM 2019-nCoV Assay (Seegene Inc. Seoul, Korea) with the CFX96TM instrument (Bio-Rad, Hercules, CA). The cycle threshold (Ct) of each RT-PCR reaction was extracted from the Seegene Viewer software, used for results interpretation, and recorded into a dedicated Excel database. The test was considered positive when at least one of the three investigated genes had a Ct below 40. As the N gene assay resulted 10 times more sensitive that the ORF1b gene for detecting viral infection [4], the viral loads were estimated basing on the Ct values for the N target using the ΔCt method (Ct sample—Ctref: = ΔCt − N), as previously described [5].

2.1.2. Virus Isolation

For SARS-CoV-2 isolation, the Vero E6 cell line (African green monkey kidney cells) was used [6,7]. Cells were cultured in Eagle's minimal essential medium (EMEM) (Life Technologies, Carisbad, CA, USA) supplemented with 10% (vol/vol) fetal bovine serum (FBS) (Life Technologies, Carisbad, CA, USA), and 100 U/mL penicillin and streptomycin (Life Technologies, Carisbad, CA, USA).

For the virus isolation from swab, cells were plated into a 25 cm^2 cell culture flasks (Corning, CLS430168) at a confluency of 70–80% in 6 mL EMEM with 6% FBS and incubated overnight at 37 °C. The following day, 1500 µL of the swab medium was incubated with 500 µL of an antibiotic solution (2000 U/mL of penicillin/streptomycin and 300 U/mL of neomycin) for 1 h at room temperature. The 2 mL of suspension was then inoculated on the monolayer of the VeroE6 cells. The flask was incubated at 37 °C for 1 h.

After incubation, 4 mL of EMEM with 6% fetal bovine serum (FBS) was added and incubated again at 37 °C for 72 h [8]. Each day, 200 µL of EMEM were collected from each flask for biomolecular testing. The EMEM 6%FBS was replaced every 72 h. The observation lasted for a week. The result was defined on the basis of cytopathic effect (subjective reading) combined with the positivity of the RT-PCR test (objective reading) in supernatant. All procedures for viral culture followed the laboratory biosafety guidelines.

2.1.3. Definition of the Sensitivity Level of the Isolation Test

To establish a sensitive procedure for virus isolation in cell culture, two viral suspensions obtained from two SARS-CoV-2 Italian patients containing known virus concentrations (100 $TCID_{50}$) were tested.

Serial dilutions of both suspensions were made to obtain infectious viral particles at various concentrations in 2 mL of EMEM containing 6% FBS. Each virus dilution was seeded on a Vero E6 cell monolayer and incubated at 37 °C. After one hour of incubation, a further 4 mL of EMEM 6% FBS was added and, at the same time, 200 µL of the supernatant were taken, on which the RNA extraction and the RT-PCR test were carried out to verify the value of the starting Ct. For each viral dilution, four tests were performed.

Every 24 h, the infected cell monolayer was visually inspected by light microscopy to check for the presence of cytopathic effect, and 200 µL of supernatant were collected, on which the RNA extraction and the RT-PCR test were carried out to verify the Ct value. After 72 h from the beginning of the incubation, the medium was replaced.

For each time point, one step reverse transcription PCR was performed to detect the RdRp gene, as described by Corman, V.M. et al. [9], as this target is the most specific one for the detection of Sars-CoV-2. Briefly, viral RNA was extracted from medium by QIAamp Viral RNA Mini Kit (Qiagen, Hilden, Germany), following the manufacturer protocol.

A 25-µL reaction was set up containing 5 µL of RNA, 12.5 µL of the 2× reaction buffer provided with the Superscript III one step RT-PCR system with Platinum Taq Polymerase (Invitrogen, Carlsbad, CA, USA), 1 µL of reverse transcriptase/Taq mixture from the kit, 0.4 µL of a 50 mM magnesium sulfate solution, 1.5 µL of Forward primer (10 µM, GTGARATGGTCATGTGTGGCGG), 2 µL of Reverse primer (10µM, CARATGTTAAASACACTATTAGCATA), and 0.5 of probe (10 µM FAM-CAGGTGGAACCTCATCAGGAGATGCBBQ).

All oligonucleotides were synthesized and provided by Invitrogen (Carlsbad, CA, USA). Thermal cycling was performed at 55 °C for 10 min for reverse transcription, followed by 95 °C for 3 min and then 45 cycles of 95 °C for 15 s and 58 °C for 30 s.

Overall, the experiment lasted 120 h. Infectious virus was considered to be present in those wells that showed a combined reduction of the Ct value and the presence of a cytopathic effect. Isolation in flasks with 10, 5, and 1 viral infecting doses occurred within 72 h in all cases. In the tests carried out using 0.5 and 0.1 viral infecting doses, only one isolation occurred within 72 h in the 0.5 dose group, and one isolation occurred at 96 h in the 0.1 dose group (Tables 1 and 2).

Table 1. Data relating to cytopathic effect of each dilution detected at 72, 96, and 120 h of incubation.

Infectious Viral Doses (TCID50)	72 h	96 h	120 h	72 h	96 h	120 h
	Cytopathic Effect	Result of Tests	Cytopathic Effect	Cytopathic Effect	Result of Tests	Cytopathic Effect
10	YES	Positive 4/4—end test				
5	YES	Positive 4/4—end test				
1	YES	Positive 4/4—end test

Notes: (Median Tissue Culture Infectious Dose (TCID50)).

Table 2. Data resulting from the comparison of cytopathic effect and Ct values obtained by PCR analyses in relation to the different infectious viral doses used to standardize the test. The indicated Ct values are the average medium ones, obtained by the four replicates.

Infectious Viral Doses (TCID50)		72 h	96 h	120 h
	Starting Ct (RdRp)	Ct Value (RdRp)	Ct Value (RdRp)	Ct Value (RdRp)
10	27.33	12.31	-	
5	28.60	12.10	-	
1	24.42	17.13	13.73	-
0.5	30.77	32.56	36.02	Negative
0.1	32.67	34.67	34.46	Negative

Notes: Cycle thresholds (Ct) of the *RdRp* gene. Median Tissue Culture Infectious Dose (TCID50).

2.2. Statistical Analysis

All analysis was performed using SPSS 26 software (IBM, Armonk, NY, USA). Numerical data were represented with mean ± standard deviation, while categorical variables were represented as counts and percentage. Any statistical differences in the laboratory data of population at baseline and nasopharyngeal control swab were performed using *t*-test paired samples or Mann–Whitney U–test, as appropriate. A *p*-value of less than 0.05 was considered statistically significant.

3. Results

We selected 84 subjects whose nasopharyngeal swab was still RT-PCR-positive at T1. Table 3 summarizes the characteristics of the subjects at baseline. The average age was 46 ± 20.29, (19.1% female), 51.2% of patients were African, and the remaining were Caucasian. At admission, 40.5% of the subjects had radiologically confirmed pneumonia, the overall average PaO_2 was 72.35 ± 12.12, $PaCO_2$ 36.2 ± 5.2, with an average P/F ratio of 315 ± 83.15. Five percent of patients underwent oxygen therapy, and 9.6% underwent high flow nasal cannulae (HFNC) or continuous positive airway pressure (CPAP) ventilation.

Table 3. Characterization of the study group at baseline (N = 84).

Patient Characteristics	
Age, years	46.07 ± 20.29
Females, n (%)	16 (19.1)
African, n (%)	43 (51.2)
Current or former smoker, n (%)	24 (28.6)
Comorbidities, n (%)	
Asthma or COPD	3 (3.6)
Chronic cardiac disease	27 (32.2)
Diabetes	10 (12)
Alzheimer	5 (6)
Chronic neurological disease	8 (9.6)
Radiographic feature, n (%)	
Pneumonia	34 (40.5)
Respiratory failure, n (%)	
Oxygen therapy	13 (15.5)
HFNC or CPAP	8 (9.6)

Continuous data are expressed as mean ± standard deviation, numerical as count (percentage). Notes: COPD: chronic obstructive pulmonary disease; CPAP: continuous positive airway pressure; HNFC: high nasal flow cannulae.

Nasopharyngeal swabs were performed, on average, on day 19.95 ± 5.71 in 80 patients, while in four persistently positive cases these were performed at day 41, 43, 50, and 70, respectively. As expected, Ct values for the N gene were lower in the first nasopharyngeal swab than in the control one (26.04 ± 5.26 vs. 35.59 ± 3.95, $p < 0.001$—Table 4, Figure 1). The first group of patients became negative after two consecutive swabs, about 10 days after culture (29.50 ± 9.17), while the four persistently positive patients needed 53, 61, 72, and 104 days, respectively, to obtain a double negative response.

Table 4. Comparison between laboratory characteristics of patients at T0 and at T1 (interval of 19.95 ± 5.71 days).

Parameters	T0			T1		
	Min	**Max**	**Mean ± SD**	**Min**	**Max**	**Mean ± SD**

RT-PCR NcT value						
	14.5	38.9	26.04 ± 5.26	17.40	38.9	35.59 ± 3.95 **

Data are expressed as mean ± standard deviation, with the minimum and maximum values found. * $p < 0.05$, ** $p < 0.01$ vs. baseline. Notes: CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; IL-6: Interleukin 6; NcT: cycle thresholds (Ct) of *N* gene; $PaCO_2$: partial pressure of arterial carbon dioxide; P/F ratio: arterial partial pressure of oxygen (PaO_2) to fraction of inspired oxygen (FiO_2); WBCs: white blood cells.

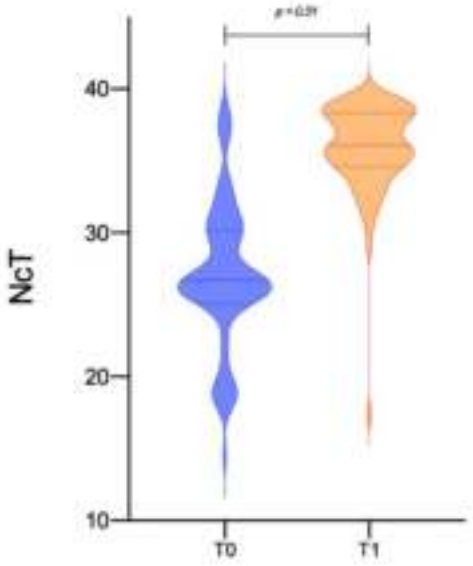

Figure 1. Comparison of cycle threshold (Ct) values at T0 (positive nasopharyngeal swab at hospital admission) and at T1 (nasopharyngeal control swab at clinical recovery performed after 19.95 ± 5.71 days from T0) for the *N* gene in a population of 84 patients described by Violin plot).

Using a sensitive virus culture method able to detect even fractions of viral infectious units, the samples from 83 patients were negative at viral culture, and the RT-PCR on the respective supernatants always confirmed the absence of viral growth (Figure 2a). Only in one case (1.19%) a cytopathic effect was observed in the corresponding cell culture at 96 h post-seeding (Figure 2b), and a relevant reduction of the viral load (increase of Ct from 31 to 38) in RT-PCR was also observed. However, the patient had a presumably delayed clearance because he was affected by Acute Myelogenous Leukaemia (AML) when he acquired the SARS-CoV-2 infection and was under chemotherapy treatment; this subject resulted negative to a nasopharyngeal swab ten days later.

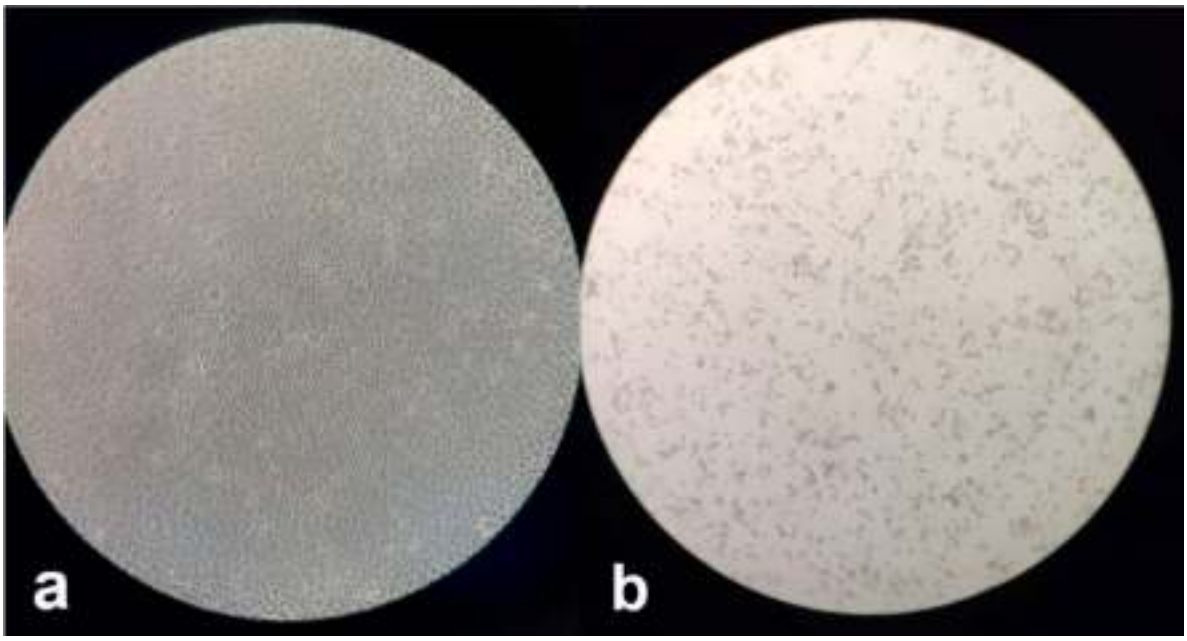

Figure 2. Viral cultures examined by a microscope at 5× magnification: (**a**) Absence of viral growth, as shown by complete confluence of Vero E6 cells; (**b**) Cytopathic effects consisting of rounding and detachment of cells in Vero E6 cell cultures at 96 h post-seeding.

4. Discussion

This study shows that the positivity of RT-PCR on nasopharyngeal swab performed during a follow up check in recovered COVID-19 patients about 20 days after symptoms onset does not coincide with the presence of the infectious virus established with the virus culture method. The main implication of these findings is that clinically recovered patients, in >98% of cases, are no longer contagious, despite the presence of vestigial virus components detected by RT-PCR. Since the beginning of the pandemic, many studies have tried to estimate the infectivity according to the clinical features and to the viral load detected by diagnostic RT-PCR [10,11]. According to an analysis made by He et al. [12], the infectiousness of COVID-19 peaks early, around the onset of symptoms, and declines within 8 days, as proven by analyzing serial time intervals between symptoms onset in two individuals in a contagious chain.

The most reliable method for COVID-19 diagnosis is RT-PCR [13] based on the detection of nucleic acid from the SARS-CoV-2 in upper and lower respiratory specimens (such as nasopharyngeal or oropharyngeal swabs, sputum, lower respiratory tract aspirate, bronchoalveolar lavage, and nasopharyngeal wash/aspirate or nasal aspirate). Ct values may be converted to Log10 RNA copies/mL using calibration curves based on quantified sample RNA transcripts, providing a quantitative result [14].

Huang et al. [15] studied 60 specimens from 50 patients, performing RT-PCR for genes E, N, and Nsp12, as well as in vitro virus cultivation on Vero E6 cells. The specimens resulting positive in culture had significantly higher Ct values for all three genes. They

further proved that the analysis of structural and non-structural genes in both culturable and non-culturable samples might help to identify actively replicating viruses.

La Scola et al. [16] highlighted a correlation between Ct values and the probability of isolating the virus in vitro; from a group of 183 samples, virus isolation always (100%) occurred in swabs with a Ct between 13 and 17, and viral growth was never observed with Ct > 34.

Arons et al. [17] analyzed specimens from 76 residents in a skilled nursing facility and found that, after classification on symptoms, no significant difference was observed in the Ct values of patients, and there was no significant difference according to symptoms intensity. The analysis was performed with RT-PCR on nucleocapsid gene regions N1 and N2. A parallel in vitro test of viral culture found no virus rescue after 9 days from symptoms onset.

Wölfel et al. [14] performed RT-PCR for E and RdRp genes and in vitro culture of nasopharyngeal swab, sputum, sera, and stool samples from none patients with mild disease. They found that RT-PCR can result positive for as long as 28 days from symptoms onset. No virus could be cultivated from samples collected after 8 days, and could also never be cultivated for viral loads with less than 10^6 copies of RNA. Despite the small size of the study population, the time for virus isolation success, estimated via a probit model, was 9.78 days (CI 8.45–21.78). Notably, they observed an earlier peak of shedding in the nasal-pharyngeal swab as compared to sputum, and this was higher in intensity in patients with pneumonia. Urine and serum samples never showed viral growth in vitro, while stool samples showed a prolonged viral RNA shedding, extending far beyond the virus isolation window.

Bullard et al. [18] performed a comparison between SARS-CoV-2 viral culture on Vero cells with RT-PCR; they analyzed 90 samples (nasopharyngeal and endotracheal swabs) from patients at different time points from symptoms onset (0 to 21 days) and observed that no virus growth is obtained, either after 8 days from symptoms onset or when Ct > 24 on RT-PCR. For each 1 unit increase of Ct, the odds ratio of infectivity decreased by 32%, while, for each day increase from symptoms onset, the decrease was by 37%. The limits to this study are that only one gene (E) has been analyzed and no longitudinal analysis has been performed.

In a pre-print work by Van Kampen et al. [19], a study of samples from 129 patients with severe/critical disease has shown a possible longer infectious viral shedding as compared to mild and moderate cases. They observed a correlation between viral load and the probability of isolating the virus in vitro. A reduction to less than 5% of this probability was observed for viral loads of less than 10 copies or after 15.2 days after symptoms onset.

In our study, the culture from the swabs of positive patients is able to define the presence of live and viable viral particles within 96 h from the seeding on Vero E6 monolayer cells. Furthermore, the sensitivity of the test is confirmed by the fact that, even with dilutions in which 0.5 and 0.1 infectious viral particles are expected to be present, 25% of the cultures provided successful virus isolation. These results confirm the viral isolation method as the most sensitive and specific one, and it is considered the gold standard according to classical virological methods, capable of discriminating persons that harbor the live infectious virus from those that probably harbor dead virus particles or fragments of viral RNA not yet detected by RT-PCR.

Compared to the studies in the literature, our preliminary results demonstrate that patients clinically recovered for at least three days showed the viral clearance at viral culture, and presumably they continued to not be contagious. There is no doubt that both the RT-PCR and the viral culture have limits, so non-infectivity cannot be excluded with absolute certainty, and genomic and sub-genomic RNAs analysis could provide more evidence about the real infection risk. Deeper studies are necessary to better evaluate this aspect. However, according to our results, and in line with the data that emerged from the other few studies performed on cell cultures, we can suppose that it might not be strictly necessary to perform control swabs to demonstrate the clearance of the virus when patients

have clinically recovered for at least three days. Further studies, involving patients with a shorter time of recovery, that is, earlier than 14 days of hospitalization, might conclusively prove this observation and significantly shorten the length of hospitalization as well as time of social isolation.

Asymptomatic transmission of covid-19

What we know, and what we don't

Allyson M Pollock, [1] James Lancaster[2]

The UK's £100bn "Operation Moonshot" to roll out mass testing for covid-19 to cities and universities around the country raises two key questions. How infectious are people who test positive but have no symptoms? And, what is their contribution to transmission of live virus?

Unusually in disease management, a positive test result is the sole criterion for a covid-19 case. Normally, a test is a support for clinical diagnosis, not a substitute. This lack of clinical oversight means we know very little about the proportions of people with positive results who are truly asymptomatic throughout the course of their infection and the proportions who are paucisymptomatic (subclinical), presymptomatic (go on to develop symptoms later), or post-infection (with viral RNA fragments still detectable from an earlier infection).

Earlier estimates that 80% of infections are asymptomatic were too high and have since been revised down to between 17% and 20% of people with infections.[1 2] Studies estimating this proportion are limited by heterogeneity in case definitions, incomplete symptom assessment, and inadequate retrospective and prospective follow-up of symptoms, however.[3] Around 49% of people initially defined as asymptomatic go on to develop symptoms.[4 5]

It's also unclear to what extent people with no symptoms transmit SARS-CoV-2. The only test for live virus is viral culture. PCR and lateral flow tests do not distinguish live virus. No test of infection or infectiousness is currently available for routine use.[6-8] As things stand, a person who tests positive with any kind of test may or may not have an active infection with live virus, and may or may not be infectious.[9]

The relations between viral load, viral shedding, infection, infectiousness, and duration of infectiousness are not well understood. In a recent systematic review, no study was able to culture live virus from symptomatic participants after the ninth day of illness, despite persistently high viral loads in quantitative PCR diagnostic tests. However, cycle threshold (Ct) values from PCR tests are not direct measures of viral load and are subject to error.[10]

While viral load seems to be similar in people with and without symptoms, the presence of RNA does not necessarily represent transmissible live virus. The duration of viral RNA shedding (interval between first and last positive PCR result for any sample) is shorter in people who remain asymptomatic, so they are probably less infectious than people who develop symptoms.[11]

Viral culture studies suggest that people with SARS-CoV-2 can become infectious one to two days before the onset of symptoms and continue to be infectious up to seven days thereafter; viable virus is relatively short lived.[7] Symptomatic and presymptomatic transmission have a greater role in the spread of SARS-CoV-2 than truly asymptomatic transmission.[1 2 12 13]

The transmission rates to contacts within a specific group (secondary attack rate) may be 3-25 times lower for people who are asymptomatic than for those with symptoms.[1 12 14 15] A city-wide prevalence study of almost 10 million people in Wuhan found no evidence of asymptomatic transmission.[16] Coughing, which is a prominent symptom of covid-19, may result in far more viral particles being shed than talking and breathing, so people with symptomatic infections are more contagious, irrespective of close contact.[17] On the other hand, asymptomatic and presymptomatic people may have more contacts than symptomatic people (who are isolating), underlining the importance of hand washing and social distancing measures for everyone.

Missed opportunity

By failing to integrate testing into clinical care, we have missed an important opportunity to better understand the role of asymptomatic infection in transmission. Given the variation in prevalence and testing strategies by region, the proportions of people with positive and negative test results should be published alongside the purpose of the testing strategy and the population tested (screening healthy populations in schools, universities, and health and social care, or testing people with symptoms). Government regulations on recording the age, ethnicity, sex, and place of residence of people with positive results must also be followed.[18]

Searching for people who are asymptomatic yet infectious is like searching for needles that appear and reappear transiently in haystacks, particularly when rates are falling.[19] Mass testing risks the harmful diversion of scarce resources. A further concern is the use of inadequately evaluated tests as screening tools in healthy populations.[20]

The UK's testing strategy needs to be reset in line with the Scientific Advisory Group for Emergencies' recommendation that "Prioritising rapid testing of symptomatic people is likely to have a greater impact on identifying positive cases and reducing transmission than frequent testing of asymptomatic people in an outbreak area."[21]

Testing should be reintegrated into clinical care with clinical and public health oversight and case definitions based on clinical diagnosis. Carefully designed prospective studies of cases and contacts are needed to estimate transmission rates by people

with and without symptoms. These should include careful investigations of outbreaks—for example, testing all contacts of people with a clear history of exposure, especially in high risk environments such as nursing homes, prisons, and other institutional settings.

Coronavirus infection surveys by the Office for National Statistics[22] and the REACT survey[23] could be expanded to include clinical follow-up of participants combined with tests of viral load and viral cultures. The absence of strong evidence that asymptomatic people are a driver of transmission is another good reason for pausing the roll out of mass testing in schools, universities, and communities.

Group A Streptococci Among School-Aged Children: Clinical Characteristics and the Carrier State

Judith M. Martin, MD; Michael Green, MD, MPH; Karen A. Barbadora, MT(ASCP); and Ellen R. Wald, MD

ABSTRACT. *Objective.* **A 4-year longitudinal study of school-aged children was conducted to describe the clinical characteristics and epidemiologic features of infections with group A streptococci (GAS).**

Methods. **Between 1998 and 2002, surveillance throat cultures were performed twice per month (October to May) for a cohort of elementary school children in Pittsburgh, Pennsylvania. In addition, throat cultures were obtained during any respiratory illness. Erythromycin and clindamycin susceptibility testing was performed for all isolates. Molecular typing was performed with field-inversion gel electrophoresis. Representative isolates from each field-inversion gel electrophoresis group were *emm* typed. Strict definitions were used to characterize each GAS infection. Children were classified into 4 categories each year, ie, single episode, recurrent episodes, carriers of GAS, and no infections.**

Results. **A total of 48 to 100 children per year were studied for 4 years; 61 (49%) were male. The mean age was 9.6 years (range: 5–15 years). A total of 5658 throat cultures were performed; 878 (15.5%) were positive for GAS. Antimicrobial agents were used to treat 209 episodes of infection. Thirteen *emm* types were observed during the 4-year period. GAS were isolated most often from children who were carriers; isolates from single episodes were next most common. Children carried a single *emm* type for a mean of 10.8 weeks (range: 3–34 weeks). Carriers were likely to be classified again as carriers in subsequent years and frequently switched *emm* types. Sixty-two percent of the children had ≥1 year with no infections.**

Conclusions. **GAS infections are common among school-aged children. The majority of positive throat cultures observed in this longitudinal study were obtained from children who were carriers of GAS. Carriers switched *emm* types but tended to become carriers repeatedly during the study. Practitioners should consider treating children known to be GAS carriers when they develop a new illness that is consistent with streptococcal pharyngitis, because they may acquire new *emm* types and be at risk for rheumatic heart disease. *Pediatrics* 2004;114:1212–1219; *group A streptococcus, surveillance, epidemiology, pharyngitis, carrier.***

ABBREVIATIONS. GAS, group A streptococci; FIGE, field-inversion gel electrophoresis; CFU, colony-forming units.

Group A streptococci (GAS) (*Streptococcus pyogenes*) are the most common cause of bacterial pharyngitis among children and adults.[1] They are the leading cause of acquired heart disease among children throughout the world, and increasingly they are a major cause of deaths attributable to bacterial sepsis among both children and adults.[2–4]

Children are the major reservoir of GAS and are the target population for pharyngitis, as well as the suppurative and nonsuppurative complications caused by GAS.[2] They represent the pool from which adults with severe invasive disease acquire their infections.[4] The peak age incidence for infections caused by GAS is between 5 and 15 years. The frequency of GAS infections decreases markedly after 15 years of age unless large numbers of young adults from diverse locations are assembled in close quarters, as in military settings.[5]

GAS were previously grouped into >100 different serotypes with a typing system based on the M-protein in the cell wall. A recent alternative to serotyping is the designation of *emm* type by sequencing the 5′-terminal end of the *emm* gene.[6] It is not known whether children develop repeated infections with the same or different *emm* types of GAS. There is limited understanding of why and how children become immune to infection with GAS. Previous studies of large cohorts of children were performed before the availability of *emm* typing, when the majority of isolates could not be serotyped for the M-proteins.[7–10] The purpose of this longitudinal study was to describe the epidemiologic features of GAS infections in a group of school-aged children, with the use of modern molecular methods.

METHODS

Setting and Participants

A longitudinal study of the epidemiologic features of GAS infections in a private, tuition-supported, elementary school was initiated in 1998. This school serves 285 children and is located in Pittsburgh, Pennsylvania. Forty percent of the children who attend have parents who are faculty members of the University of Pittsburgh. Children attend kindergarten through grade 8. They are divided into 3 major cohorts according to age, ie, 5–7 years, 8–10 years, and 11–15 years. Within each group, there are 4 homerooms. Placement for each instructional setting (eg, math and reading) is based on readiness rather than age or grade level. Therefore, there is significant mixing between groups of students. Class size is limited to 24 students, and most classes have 12 to 15 students. All classrooms were represented in the study.

Downloaded from www.aappublications.org/news at McMaster University on March 16, 2021

All students attending the school were invited to join the study, but participation was voluntary. All students who were willing to participate were enrolled. The protocol was approved by the institutional review board of Children's Hospital of Pittsburgh, as well as by the school. Informed consent was obtained from ≥1 of the parents of the children who participated. The children provided assent.

Processing of Throat Cultures

Throat cultures were performed for each child approximately every 2 weeks during each school year, from October through May. Each child underwent a minimum of 17 cultures per school year. A throat culture was also performed each time a child developed a new respiratory illness, to ensure the identification of all new acquisitions of GAS. Study personnel were "on call," and an ill child was examined within 1 day after the identification of a new respiratory illness. If a child saw his or her personal physician because of an illness, then a throat culture was performed by the practitioner and retrieved by study personnel. Follow-up cultures were performed 2 to 4 days after completion of antimicrobial therapy for all new acquisitions of GAS that were treated. Follow-up cultures were performed 1 week after the initial culture when new positive cultures for GAS were not treated.

Throat culture specimens were obtained with a rayon-tipped swab (BBL Becton Dickinson, Sparks, MD), transported to the laboratory within 2 hours, and processed the same day with standard techniques, as described previously.[11] Beginning in October 2000, the relative numbers of GAS colonies were indicated on a scale of 1 to 4 (1+, <10 colony-forming units (CFU); 2+, >10 CFU but <50 CFU; 3+, >50 CFU but streptococci not predominant; 4+, streptococci predominant). More than 90% of the throat swabs were obtained by the principal investigator (J.M.M.); the processing of throat cultures was overseen by 1 senior laboratory technician (K.A.B.).

Typing of the GAS Isolates

The genetic relatedness of the GAS strains was investigated with field-inversion gel electrophoresis (FIGE), a type of pulsed-field gel electrophoresis, with previously described methods.[12,13] A 4-mm slice of each GAS plug was initially digested with 24 units of *Sma*I in 1× restriction buffer (New England Biolabs, Beverly, MA). Similar digestions were conducted with *Apa*I and/or *Eag*I, in their respective restriction buffers, for isolates that could not be digested with *Sma*I.[11]

The migration of DNA bands was compared with that of the λ ladder standard. Bands within the 50- to 250-kilobase range were used for analysis. Comparison of banding patterns was performed with visual inspection, and interpretation of clonal relatedness was based on guidelines proposed by Tenover et al.[14] One or more representative isolates from each FIGE type from each year and 4 erythromycin-resistant strains from the third year were selected and sent to the Centers for Disease Control and Prevention for *emm* typing.[6]

Susceptibility Testing

GAS isolates were screened initially for their susceptibility to erythromycin and clindamycin with the Kirby-Bauer disk diffusion test (BBL Becton Dickinson), on Mueller-Hinton agar with 5% sheep's blood, according to published guidelines and as described previously.[11,15] The minimal inhibitory concentration was then determined with the E-test (AB Biodisk, Piscataway, NJ) for isolates that were either intermediate or resistant in susceptibility to erythromycin or clindamycin. To screen for the mechanism of resistance, double-disk diffusion tests were performed.[16] Resistance to erythromycin was classified as an inducible MLS_B phenotype, a constitutive MLS_B phenotype, or an M phenotype. All GAS isolates were stored at −70°C for later use.

Definitions

Physical examination of the pharynx was performed for each throat culture specimen obtained. At the time of culture sample collection, the child was questioned regarding his or her symptoms, with a standard data sheet. In addition to the symptoms reported by the child, information regarding symptoms was solicited from a parent for each illness visit. The physical examination results, as well as the symptoms, were documented in a database. When any throat culture was positive for GAS, the principal investigator (J.M.M.) called a parent within 48 hours after obtaining the positive result. A standard instrument was used to assess symptoms and duration.

Each child was classified into 1 of 4 categories for each school year. The following definitions were used for each subject from whom an isolate of GAS was recovered. A child was classified as a carrier if GAS were recovered from ≥2 sequential surveillance cultures obtained ≥1 week apart in the absence of symptoms. Children were assigned to this category if they were ever GAS carriers during a school year. This included children who cleared their carriage and later had a single throat culture positive for GAS, with or without symptoms. A child was categorized as having recurrent episodes if either clinical or subclinical acquisitions of GAS were documented and separated by a minimum of 1 negative culture (and a 3-week interval) while the child was not receiving antimicrobial therapy. This designation was independent of GAS typing results. A child was designated as having had a single episode if a single positive throat culture was preceded and followed by negative throat cultures during a single school year. Children whose throat cultures were negative for GAS throughout a single school year were designated as having no infections.

All episodes of GAS-positive throat cultures were classified as being either clinical or subclinical. Clinical episodes were those associated with any respiratory symptoms. Typical episodes were those in which sore throat was a prominent complaint. Atypical episodes were those in which the child reported the new onset of rhinorrhea and/or cough, without sore throat. Subclinical episodes occurred when a child with a single positive throat culture had no symptoms.

The outcome of each episode of classic GAS pharyngitis (in which sore throat was the prominent complaint) was classified both clinically and bacteriologically in follow-up evaluations, on the basis of the result of the throat culture and the presence of clinical symptoms. An episode was defined as a clinical cure if the child no longer had symptoms of pharyngitis, as a clinical failure if the child had persistent symptoms of pharyngitis, as a bacteriologic cure if the child had a negative follow-up throat culture for GAS, and as a bacteriologic failure if the child had a positive follow-up throat culture for GAS of the same FIGE type as the initial infection. Each episode in which a child experienced a second positive culture after a bacteriologic cure was classified as a new acquisition if the child had a throat culture that was positive for GAS with a different FIGE pattern or *emm* type, compared with the child's previous GAS isolate, or as a reacquisition if the child had a throat culture that was positive for GAS with the same FIGE pattern or *emm* type as the child's previous GAS isolate. Duration of carriage was defined as the length of time between the first positive culture of one *emm* type and the first negative culture or the first positive culture with a new *emm* type during the school year.

Treatment

Patients with new respiratory complaints of sore throat or rhinorrhea (with or without sore throat) and a new positive throat culture for GAS were treated with orally administered penicillin V or amoxicillin by a single study physician (J.M.M.). Children with rhinorrhea without sore throat were treated only if the child's previous 2 throat cultures were known to have been negative for GAS. This decision was made because western Pennsylvania is known to have a high incidence of acute rheumatic fever and many children diagnosed as having rheumatic fever do not recall an antecedent sore throat.[17–19] Unlike clinical practice, the circumstances of the study afforded the opportunity to identify readily episodes of new acquisition of GAS.

The dose of penicillin V or amoxicillin used for all children was 500 mg twice per day for 10 days. At the beginning of the longitudinal study, erythromycin or azithromycin was prescribed only for children who were allergic to penicillin. Beginning in February 2001, either cephalexin or clindamycin was used for patients who were allergic to penicillin or amoxicillin. These medications were dosed on a milligrams per kilogram basis for a 10-day course, with the exception of azithromycin, which was used for 5 days. Treatment was not prescribed when a surveillance culture was positive for an asymptomatic child. No attempts were made to eradicate the carrier state.

Downloaded from www.aappublications.org/news at McMaster University on March 16, 2021

Statistical Methods

Data were entered into a Microsoft Access (Microsoft, Redmond, WA) database. All of the data from the laboratory and a random sample of 10% of the entries were double-checked for accuracy. Calculations were made with STATA 7 (Stata Corp, College Station, TX). χ^2 analysis was used for comparisons of dichotomous variables, and the *t* test was used for comparisons of continuous variables.

RESULTS

Demographic Characteristics of the Study Population

A total of 125 children participated in this longitudinal study at some time between October 1998 and May 2002. Figure 1 summarizes the subjects' entry into and departure from the study. Of the 125 children, 33 (26%) were monitored for 4 years, 50 (40%) were monitored for 3 years, 22 (18%) were monitored for 2 years, and 20 (16%) were monitored for only 1 year.

Forty-nine percent of the students were male; 73% were white, 13% Asian, 7% Hispanic, and 7% black. The demographic features of the children in each study year were similar to those of the school as a whole. The mean age of subjects for the entire study was 9.6 years (range: 5-15 years).

Laboratory Results

Table 1 shows the number of cultures that were performed in each year of the study and the number and percentage that were positive for GAS. The modest increase in the proportion of positive cultures was significantly different when year 3 was compared with years 1 and 4. No isolate of GAS was determined to be resistant to clindamycin. In the first 2 years of the study (1998–2000), there were no isolates that were resistant to erythromycin. However, as previously reported, 156 of 318 GAS isolates (49%) and 126 of 238 GAS isolates (53%) in years 3 and 4 of the study, respectively, were found to be resistant to erythromycin.[11] Table 2 shows the distribution of *emm* types of the GAS isolates for the 4 years. Thirteen different *emm* types circulated during the 4-year study period, with an average of 9 *emm* types per year. The predominant *emm* type was different each year for the first 3 years. The most prominent *emm* type in year 2 was not observed among the cohort in the previous year. In January of year 3, an erythromycin-resistant strain was isolated for the first time

TABLE 1. Comparison of the Percentages of GAS-Positive Throat Cultures According to Study Year

Year	No. of Children	No. of Throat Cultures Performed	No. (%) of Throat Cultures Positive for GAS
1998–1999	48	860	115 (13.4)
1999–2000	75	1340	208 (15.5)
2000–2001	100	1794	318 (17.7)
2001–2002	96	1664	237 (14.2)
Total		5658	878 (15.5)

The majority of children were monitored for 2 or 3 years. All *P* values were not significant except for comparisons of the numbers of positive cultures for years 1998–1999 versus 2000–2001 ($P = .004$) and 2000–2001 versus 2001–2002 ($P = .005$).

94	0	1 (0.5)	0	0
Total *emm* types	6	11	10	8

* There were ≥2 FIGE patterns observed for each of these *emm* types.

(*emm* 6, M phenotype, and *mef(A)* positive).[11] This became the predominant strain during years 3 and 4 of the study. There were 22 *emm* 6 isolates in years 1 and 2 of the study; however, they were not resistant to erythromycin and they had different FIGE patterns, compared with the epidemic strain.

The density of GAS was recorded for each throat culture after October 2000. Density did not correlate with clinical category. For children with typical symptoms, 33% of the throat cultures were 1+ positive and 45% were 4+ positive; for children with no symptoms, 39% of the cultures were 1+ positive and 24% were 4+ positive; for children with atypical symptoms, 54% of the cultures were 1+ positive and 21% were 4+ positive.

Classification of Isolates According to Symptoms

Each child with a positive culture for GAS was classified according to symptoms, with strict definitions. No symptoms were present (carriers plus transient subclinical infections) at the time of recovery for the majority of isolates (75%; range: 74–80% for each year). For the remaining positive cultures, 18% (range: 10–20% for each year) were associated with typical symptoms and 7% (range: 6–10% for each year) were associated with atypical symptoms. Overall, 8% of all episodes of illnesses associated with nasal congestion and/or cough but without sore throat were positive for GAS. This number excludes illnesses among children who were already known to be GAS carriers. There were no significant differences in the mean ages of children with no symptoms, typical symptoms, and atypical symptoms.

Children experienced episodes of acute GAS pharyngitis throughout the school year. The number of episodes of positive throat cultures associated with typical symptoms was examined according to the month of the year for each year of the study. In years 2, 3, and 4, there was a bimodal distribution of cases; the month in which episodes associated with typical symptoms peaked was variable (December, February, or April). The seasonal occurrence of episodes of GAS-positive throat cultures associated with typical symptoms and a new *emm* type was not different between children who were classified as GAS carriers and children who were not classified as carriers (P = .49).

Clinical Characteristics of Streptococcal Infections

Every child was classified into 1 of 4 groups for each year, ie, single episode, recurrent episodes, carrier, and no infections. The relative frequencies of each of the 4 categories were constant for the 4 years of the study. Little variation in the frequency of a given category was observed from year to year (Table 3). The most common classification was children with no infections (38-46%), whereas the least common category was recurrent infections (6-14%).

Fifty-six children were classified as experiencing a single episode in ≥1 school year. For the children with single episodes, 56% were associated with typical symptoms, 21% with atypical symptoms, and 23% with no symptoms. Forty of these children were monitored for ≥1 year after their single episode. Only 3 (8%) experienced a single episode in the following school year; in each case, the second episode involved a different *emm* type. Ten of the 40 children (25%) became carriers in the subsequent year, whereas 25 children (63%) had no infections in the subsequent year.

Recurrent episodes were very uncommon. They were observed for only 22 children during the 4-year period; most had only 2 episodes in 1 study year (Table 4). No more than 7 children had recurrent episodes in any given year. Twenty of the 22 children with recurrent episodes were monitored for ≥2 years, and only 2 of those children had recurrent

TABLE 3. Comparison of the Clinical Characteristics of the Children in the 4 Years of the Study

Classification	No. of Children (%)			
	1998–1999 (N = 48)	1999–2000 (N = 75)	2000–2001 (N = 100)	2001–2002 (N = 96)
No infections	18 (38)	29 (39)	39 (39)	44 (46)
Carriers	13 (27)	23 (31)	32 (32)	28 (29)
Single clinical infection	10 (21)	16 (21)	23 (23)	17 (18)

TABLE 4. Characteristics of Children With Recurrent Episodes of Infection With GAS in a Single Study Year

	No. of Patients	No. With 2 Episodes	No. With 3 Episodes	No. of Pairs of Isolates	Same *emm* Type	Different *emm* Types
Year 1	7	4	3	10	4	6
Year 2	6	5	1	7	3	4
Year 3	6	4	2	6	4	2
Year 4	7	7	0	7	4	3
Totals	26*	22	4	30	15	15

The data in the right 2 columns should add up to the number of pairs of isolates that were compared in each year. For example, in year 1 there were 4 children who had 2 episodes each; therefore, there was 1 pair of isolates to compare for each child, for a total of 4 comparisons. In year 1, there were 3 children who had 3 episodes each. For these children, the first isolate was compared with the second isolate and the second isolate was compared with the third isolate. Each child who experienced 3 episodes had 2 pairs to compare, for a total of 6 pairs in this group. For year 1, there were 4 + 6 = 10 pairs of GAS isolates to compare. The number of pairs of GAS isolates compared is indicated.
* Twenty-two different children; 2 children had recurrent episodes in each of 3 years.

episodes in subsequent years. Children were treated with an antibiotic in 19 of the episodes because they were associated with clinical symptoms. Fifty percent of recurrent episodes were with different *emm* types. The mean time between infections was 9.33 weeks (SD: 7.59 weeks), with a range of 3 to 29 weeks. Recurrent episodes with the same *emm* type versus a different *emm* type were equally likely to occur independently of 1) the interval between episodes (<30 or >30 days apart) ($P = .71$), 2) the symptoms with the first episode ($P = .73$), and 3) whether the child received an antibiotic for the first episode ($P = .5$). For children who experienced recurrences with the same *emm* type, the 2 isolates had identical FIGE types. All children with recurrences with different *emm* types also had different FIGE types. All of the children who had recurrent episodes experienced a clinical and bacteriologic cure before the second episode of infection. There were only 3 children with a single negative throat culture between episodes of GAS with the same *emm* type. For all of these children, both episodes had typical symptoms and were treated promptly with an antibiotic. The mean time between episodes of the same *emm* type for all children was 10.68 weeks, and the mean time between episodes of different *emm* types was 8.84 weeks; these values were not significantly different.

Seventy-seven children completed ≥1 study year with no infections. Twenty-eight of the 50 children (56%) monitored for >1 year continued to have no infections in subsequent study years. Twenty-two of these 50 children (44%) were monitored for 4 years. Three had no infections during the entire 4-year period. Three had no infections in 3 years, and 12 had no infections in 2 years.

Carriers of GAS accounted for 27 to 32% of the cohort in each year of the study. The mean prevalence of carriers calculated according to month was 15.9% (SD: 4.99%; range: 4.2-26%). Eleven of the 13 children who were carriers in year 1 of the study were monitored for all 4 years. Ten of the 11 (91%) were carriers in subsequent years of the study. Seven were carriers for all 4 years, 1 for 3 years, and 2 for 2 years. If children were carriers in their first year of the study, then they were significantly more likely to continue to be carriers, compared with children who were not carriers in their first year ($P < .0001$).

Fifty-three children were classified as GAS carriers at least once. Of these 53 children, 24 (45%) had a positive throat culture when their first culture was performed; they were identified as carriers at study entry. The remaining 29 children began with negative throat cultures for GAS. Thirteen of these 29 children (45%) had typical symptoms at the time of their first positive throat culture. The remaining 16 (55%) had atypical symptoms or were asymptomatic when their first carrier culture was positive. Children who were classified as carriers had variable numbers of throat cultures that were positive during that school year; 29% had <25% of all throat cultures positive for GAS, 32% had 25% to 50% of all throat cultures positive, 21% had 50% to 75% of throat cultures positive, and 18% had >75% of all throat cultures positive for GAS.

Thirty-one of the 53 children who were carriers during ≥1 school year switched *emm* types at some point. There were 107 episodes in which these 31 children switched from carrying one *emm* type to carrying a different *emm* type during a single school year. Sixteen of the 107 episodes (15%) were associated with typical clinical symptoms at the time of type switching. Most episodes of switching (85%) were not associated with any clinical symptoms. Occasionally, a child who was a carrier of one *emm* type had a clinical infection with a second *emm* type and then resumed carriage with the first *emm* type. Three children switched *emm* types 7 times in the 4 years of the study.

The mean duration of carriage of one *emm* type was 10.8 weeks (SD: 9.1 weeks; range: 2-34 weeks). By definition, the duration of carriage could not be longer than 1 school year (34 weeks), because throat cultures were not performed during the summer break. However, there were 21 occurrences in which a child was noted to carry the same *emm* type in the last throat culture of one school year and the first throat culture of the following school year. If we presume that these children remained carriers of that *emm* type throughout the summer (June to September), then the maximal duration of carriage of one *emm* type was 127 weeks. For those 21 episodes, the

Downloaded from www.aappublications.org/news at McMaster University on March 16, 2021

range was 24 to 127 weeks, with a mean duration of 49 weeks.

Treatment

There were 209 episodes that were treated with an antibiotic. Of these, 78% involved typical symptoms of classic streptococcal pharyngitis. Eighty-six percent of these were treated with amoxicillin or penicillin, 7% were treated with azithromycin (before February 2001), 5% were treated with clindamycin, and 2% were treated with cephalexin. No clinical treatment failures were observed.

DISCUSSION

In clinical practice, the assignment of GAS as the cause of an episode of pharyngitis is based on temporal association. A child is considered to have streptococcal pharyngitis if he or she has a sore throat and a positive rapid diagnostic test or culture for GAS. Although microbiologic confirmation is essential, the recovery of GAS does not establish causality. The tests do not distinguish carriage of GAS in a child with pharyngitis attributable to another cause from an acute infection caused by GAS. To establish causality, it is theoretically necessary to demonstrate the host's response to the infection in the form of antibody production. However, this antibody response (serologic evidence of infection) does not occur for 2 to 3 weeks. Furthermore, the antibody response is frequently aborted with appropriate early antibiotic therapy.[20] The unique contribution of this study is the acquisition of systematic longitudinal data for school children, which overcomes the problems of interpretation of sporadic data obtained in clinical situations. All children in this cohort were accurately classified, during each year of the study, into 4 categories, ie, single episodes, recurrent episodes, carriers, and no infections.

Longitudinal studies that described the epidemiologic features of GAS infections among school children and in families were conducted previously.[7–10] However, the lack of available antisera and molecular typing systems when those studies were performed prevented precise tracking of infections. In 1 study, as many as 90% of the GAS isolates were nontypeable.[10] The inability to type the GAS isolates prevented the accurate categorization of episodes in which GAS were recovered. In contrast, the use of FIGE techniques and *emm* typing in our study, in conjunction with careful physical examinations and determination of clinical symptoms, allowed precise classification of each episode of infection/colonization with GAS.

One of the original goals of this investigation was to study how immunity to GAS is acquired. We hypothesized that a single infection with a given *emm* type would provide partial or complete immunity to reinfection with the same *emm* type. Recurrent infections were relatively uncommon among the subjects in this study. Approximately one-half of the recurrent episodes were caused by a GAS isolate of the same *emm* type as the first infection, independent of both the time between episodes and previous antibiotic treatment. This suggests that a single infection with a specific *emm* type may not be sufficient to induce type-specific immunity or that early treatment may abort the development of type-specific immunity. However, because recurrent episodes proved to be the least common of the clinical manifestations of infection with GAS, we are limited in our ability to speculate about the induction of immunity. A larger study of children presenting with symptomatic GAS pharyngitis will be necessary for determination of the epidemiologic features of recurrent episodes.

Although recurrent episodes were least common, single episodes were frequent. When a child had a single episode in 2 subsequent school years, the episodes always involved different *emm* types. These children might have acquired some type-specific protection. Many single episodes were typical in clinical presentation; however, 21% were atypical and 23% were completely asymptomatic. Some children had a single positive throat culture temporally associated with a clinical constellation that resembled a viral upper respiratory tract infection. The association of the clinical syndrome of rhinorrhea and GAS warrants additional study, to determine whether a causal relationship exists and to assess the potential implications of this relationship.

An intriguing observation in this study was that almost 40% of children remained uninfected each school year, despite the fact that they resided within this reservoir of GAS infection. The mean age of children with no infections was similar to that of the group as a whole. More than one-half of those who were uninfected in 1 year remained free of infection in a subsequent year. The local and systemic mechanisms that provide protection under these circumstances remain unknown. Protection may be based on mucosal immunity to the specific portion of the M-protein, local or systemic immunity to the conserved portion of the M-protein, or local production of peptides with antibacterial properties.[21,22]

The traditional definition of a GAS carrier is an asymptomatic individual with a positive throat culture and no serologic response. A second accepted definition is an asymptomatic child with a GAS-positive throat culture after completion of an appropriate course of antimicrobial treatment. In an effort to maintain participation in this study, serologic data were not sought from enrolled subjects. Instead, meticulous tracking of throat culture results, GAS typing, and correlation with the presence of clinical symptoms permitted accurate classification of each positive throat culture and each child. Demonstration of the persistence of identical GAS isolates with time, in the absence of any symptoms, provides strong evidence that a child is a GAS carrier.[23] This is independent of the relative number of GAS colonies found on the culture plate or serologic information.

Carriers of GAS constituted the largest group of children with positive throat cultures in our study. The prevalence of carriage varies dramatically according to the setting in which it is studied. In previous longitudinal studies like our own, carriage rates were reported to be extremely high (up to 25%).[7–10] In contrast, carriage rates evaluated in clin-

Downloaded from www.aappublications.org/news at McMaster University on March 16, 2021

ical practice or as part of a therapeutic trial were reported to be 2.5% to 11.5%.[24–27] Our study showed the prevalence of carriage to be 27% to 32% over the course of a school year, with an average point prevalence of 15.9% for any given month of the study (range: 4.2–26%). When the point prevalence is compared with the results of clinical practice studies, the results appear to be similar. Longitudinal studies may enhance the identification of carriers because asymptomatic children undergo repeated cultures. Furthermore, symptomatic children in our study were treated primarily with penicillin and amoxicillin. Some authors think that treatment with these antimicrobial agents may result in higher carrier rates after episodes of symptomatic infection, compared with other antimicrobial drugs.[27]

There are few studies that describe the natural history of pharyngeal carriage with GAS. Our data show that carriage is both common and persistent. The duration of carriage of a single *emm* type persisted between 3 and 123 weeks. Children who cleared the carrier state spontaneously demonstrated that they were likely to become carriers again. Ten of 11 children who were GAS carriers in the first year and were monitored over time remained carriers. This phenomenon has not been noted previously and may suggest a GAS carrier phenotype. Furthermore, the use of molecular markers in our study permitted recognition of the frequent changes in *emm* types among children who were carriers. Occasionally, the acquisition of a new *emm* type by a GAS carrier was associated with clinical symptoms. Usually, the children continued to carry the new strain; rarely, they reverted to carriage of their original *emm* type.

The observation that children who are carriers of GAS often acquire infection with new *emm* types has implications for the clinical approach for children who are known to be carriers. Although the conventional teaching has been that children who are carriers of GAS are not at risk to develop acute rheumatic fever,[28] children may be at risk when they acquire new *emm* types. It was recognized previously that 5% of children who are thought to be carriers have a serologic response to infection with GAS.[29] We hypothesize that this may be explained by the acquisition of a new *emm* type. On the basis of these observations and because we practice in an area of the country with a high rate of acute rheumatic fever,[17–19] we now routinely treat all infections associated with a GAS-positive throat culture among children with typical symptoms (sore throat and absence of cough and nasal congestion), even if the child is known to be a carrier of GAS. Practitioners in other areas of the country with similarly high rates of acute rheumatic fever should consider this approach.

Thirteen different *emm* types were identified among pharyngeal isolates of GAS during this 4-year study period. There are relatively few data on the distribution and frequency of various *emm* types among children with pharyngitis. Data from North Carolina showed that 6 M types caused most disease in that community between October 1993 and May 1994.[30] Haukness et al[31] found 12 *emm* types in 63 GAS isolates from 3 clinical offices in the Chicago area, during a 3-week period. Data from a study of GAS isolates obtained between September 2001 and May 2002 in the Pittsburgh community showed 7 different *emm* types among the erythromycin-resistant isolates.[32] Information that is available regarding invasive strains suggests that there is substantial overlap in the predominant *emm* types causing disease in different locations.[33] Because invasive strains generally reflect the predominant pharyngeal strains, it is anticipated that there will be substantial overlap in the *emm* types causing pharyngeal infections in different geographic areas. A comparison of the *emm* types of pharyngeal strains recovered in different geographic areas would provide important insights into the epidemiologic features of GAS infections at a national level.

The study population in this private school might be different from populations found in neighborhood, public, or religious schools in the United States, which might limit the generalizability of these data. There is substantial mixing of students at different grade levels, because instructional settings are based on readiness rather than age. In addition, these children are from many different school districts and >20 different zip codes. They have contact with children in their neighborhoods who do not attend the same school. On one hand, this may allow exposure to a greater number of *emm* types, compared with children in more traditional public school settings; on the other hand, because all children did not participate in the study, it is possible that the number of *emm* types circulating in the school has been understated. The fact that a single individual obtained 90% of the throat swabs and that all of the cultures were processed in the laboratory by a single senior technician minimizes the variability in collection and interpretation of throat cultures.

GAS-positive throat cultures are very common among school-aged children. The majority of positive throat cultures in this longitudinal study were obtained from children who proved to be carriers of GAS. Their cultures were not associated with the symptoms of GAS pharyngitis or with acute infection. This supports the recommendation of both the American Academy of Pediatrics and the Infectious Disease Society of America that only children who present with typical symptoms should have a rapid streptococcal test or throat culture performed to detect the presence of GAS.[23,34] Although children with GAS infections may present with atypical respiratory symptoms, until there is the capability of rapidly distinguishing acutely infected patients from carriers, testing for GAS should be performed selectively in clinical settings.

This study has allowed us to describe the various clinical and subclinical manifestations of infection with GAS among school-aged children. The factors that govern the clinical expression of streptococcal infection are unknown. How and why some children regularly incorporate GAS as part of their normal flora is also unknown. Neither local nor systemic mechanisms that protect against acquisition of streptococcal infection have been delineated. Despite our

Downloaded from www.aappublications.org/news at McMaster University on March 16, 2021

long familiarity with this resurgent pathogen, many questions remain to be answered.

WHAT'S KNOWN ON THIS SUBJECT: The prevalence of group A streptococcal pharyngitis and carriage has not been systematically studied.

WHAT THIS STUDY ADDS: In this meta-analysis the authors provide clinicians with quantitative estimates of the prevalence of GAS infection and carriage in children of various ages.

abstract

OBJECTIVES: Prevalence estimates can help clinicians make informed decisions regarding diagnostic testing of children who present with symptoms of pharyngitis. We conducted a meta-analysis to determine the (1) prevalence of streptococcal infection among children who presented with sore throat and (2) prevalence of streptococcal carriage among asymptomatic children.

METHODS: We searched Medline for articles on pediatric streptococcal pharyngitis. We included articles in our review when they contained data on the prevalence of group A *Streptococcus* (GAS) from pharyngeal specimens in children who were younger than 18 years. Two evaluators independently reviewed, rated, and abstracted data from each article. Prevalence estimates were pooled in a meta-analysis and stratified according to age group.

RESULTS: Of the 266 articles retrieved, 29 met all inclusion criteria. Among children of all ages who present with sore throat, the pooled prevalence of GAS was 37% (95% confidence interval [CI]: 32%–43%). Children who were younger than 5 years had a lower prevalence of GAS (24% [95% CI: 21%–26%]). The prevalence of GAS carriage among well children with no signs or symptoms of pharyngitis was 12% (95% CI: 9%–14%).

CONCLUSIONS: Prevalence rates of GAS disease and carriage varied by age; children who were younger than 5 years had lower rates of throat cultures that were positive for GAS. *Pediatrics* 2010;126: e557–e564

Downloaded from www.aappublications.org/news at Mc Master University on March 16, 2021

Clinicians are frequently faced with the decision of whether to obtain a pharyngeal swab for rapid antigen testing and/or culture to assess for the presence of group A *Streptococcus* (GAS) pharyngitis. Because GAS can lead to serious sequelae, particularly rheumatic fever, clinicians may be inclined to test children with the slightest suspicion of pharyngitis. Conversely, it is widely known that a subgroup of asymptomatic children have GAS detected in the pharynx as part of their flora (hereinafter referred to as carriers of GAS).

Knowledge of the prevalence of GAS infection among various subgroups of children can assist clinicians in selecting children who are likely to benefit from additional diagnostic testing. Using prevalence rates as an estimate of the previous probability of disease is the first step in evidence-based practice. In children with a very low pretest probability of GAS pharyngitis, routine diagnostic testing is not necessary. In such children, an indiscriminate approach to diagnostic testing might lead to more harm than benefit, especially if the rate of carriage of GAS is high. Prevalence estimates also help clinicians in the interpretation of test results and in the treatment of children with suspected GAS pharyngitis. We conducted a meta-analysis of the prevalence of GAS infection and carriage with the aim of providing clinicians with quantitative estimates for children of various ages.

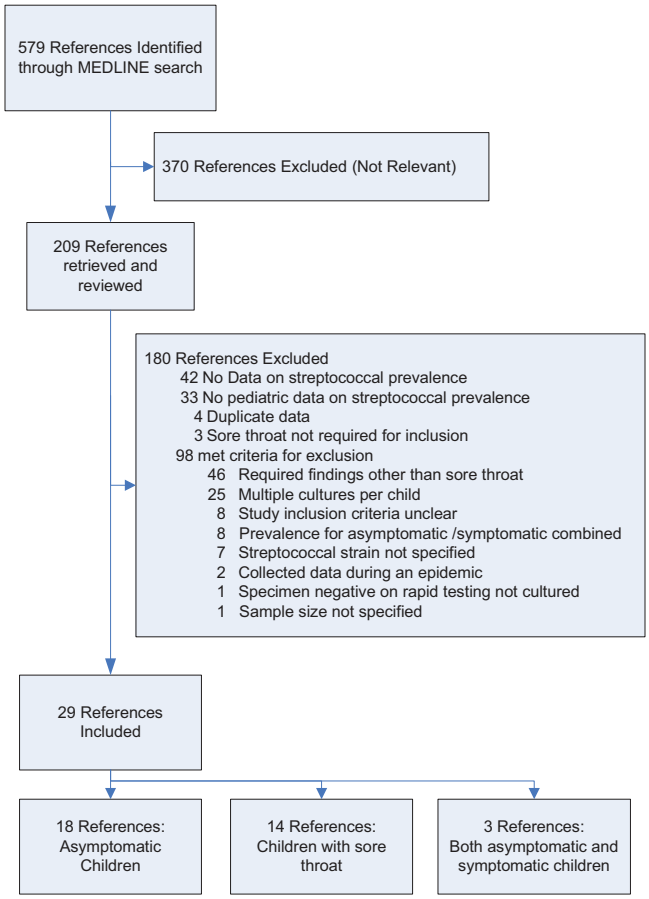

FIGURE 1
Flow diagram outlining the study selection process.

METHODS

We searched Medline (1950 through November 4, 2008) for articles on GAS pharyngitis or asymptomatic carriage in children who were younger than 18 years (Fig 1). Search terms included the following: Streptococcus infections (MeSH), streptococc*, pharyngitis, sore throat, strep throat, throat culture, tonsillitis, tonsillopharyngitis, subclinical, carrier*, carriage, coloni*, prevalence, incidence, and epidemiology. We reviewed full-text versions of articles that might contain data regarding prevalence of GAS infection and/or carriage. Only articles that were written in English, French, Italian, Spanish, and German were reviewed. Two evaluators (Drs Shaikh and Leonard) independently abstracted data from each article.

Explicit a priori inclusion and exclusion criteria were applied. We included an article when it reported data on the prevalence of GAS in children who presented to a clinician for evaluation of sore throat. Only studies that used throat cultures as the gold standard were included; studies in which rapid antigen tests were used were included only when specimens that were negative on the rapid antigen test were sent for culture confirmation. Although streptococcal grouping is ideally determined by using latex agglutination in a microbiological laboratory, sensitivity to bacitracin is often used in an office setting; therefore, we decided to include studies that used either test and to investigate whether the results differed on the basis of the test used. Because we were interested in the point prevalence of GAS, not the incidence of GAS over time, longitudinal studies in which the same child was cultured multiple times were excluded.

We excluded studies that (1) did not specifically identify the *Streptococcus* as group A, (2) included only children who lived in isolated communities or residential homes, (3) reported on an unusual epidemic of GAS, (4) included

Downloaded from www.aappublications.org/news at Mc Master University on March 16, 2021

a large proportion (>30%) of children who had received antibiotics before the throat culture, and (5) required children to have signs and symptoms other than sore throat (eg, required fever). We excluded studies that did not describe the exact signs and symptoms required for patient enrollment. For example, some of the studies reviewed stated that enrollment was based on the presence of "pharyngitis." Because pharyngitis may be defined in many ways, when no additional clarification was provided in the methods, these studies were excluded.

Because various studies enrolled children of various ages, we planned to group the studies into 2 clinically relevant age categories: <5 years and 5 to 18 years. In a number of articles, however, the lower age cutoff was not specified (eg, "we enrolled children ≤15 years of age"). Because it is likely that the majority of the children in these studies were school-aged children, we analyzed all articles that included school children together despite the different lower age cutoffs used and examined the effect of the age cutoff on the prevalence rates. Finally, when the original study presented data stratified by age, we used the data in each stratum; therefore, data from 1 article may appear in several analyses. We also examined studies that reported streptococcal prevalence among asymptomatic children; however, studies that included both asymptomatic and symptomatic children were excluded when data for the groups could not be separated.

Quality Rating

We adapted a quality assessment system for prevalence articles.[1] Two investigators (Drs Shaikh and Leonard) assessed each study independently to determine whether (1) the study was prospective, (2) the study was consecutive (defined as the systematic and unbiased enrollment of potentially eligible patients), and (3) children who had recently (≤30 days) used antibiotics were excluded. We assessed these quality indicators separately for each article; a total quality score was not calculated.[2]

Statistical Methods

Prevalence was calculated by dividing the number of children with positive cultures for GAS by the number of children who underwent throat swabs.[3] We pooled the prevalence estimates by using standard meta-analytic techniques. All reported confidence intervals (CIs) represent the 95% CIs. We planned regression analyses with regard the following factors: lower age limit of children included in the study (see previous section), setting (emergency department versus outpatient clinic), and country (United States/Canada/Europe/Australia versus others), study quality (prospective, consecutive, excluded recent antibiotic use), and year of publication.

We also examined the effect of seasonality on prevalence rates by comparing streptococcal prevalence from studies that enrolled children during their respective winter season (November through April in the northern hemisphere and May through September in the southern hemisphere) with studies that enrolled children during the entire year. For this particular analysis, only studies that were conducted in cities that were not located between the Tropic of Cancer and the Tropic of Capricorn were included.

Data were imported into Stata 10.1, and a pooled estimate of GAS prevalence was calculated by using a random-effects model with inverse-variance weighting by using the DerSimonian and Laird method.[4] Statistical heterogeneity between and within groups was measured by using the χ^2 test for heterogeneity.

Because prevalence is clearly affected by the spectrum of patients included, we expected to find significant heterogeneity among studies. To deal with heterogeneity, we used meta-regression to identify subgroups in which pooling may be acceptable. Meta-regression, a modification of linear regression, investigates the extent to which heterogeneity among studies is related to various study characteristics. Finally, we used Galbraith plots to assess visually which studies were the most heterogeneous.

To evaluate the weight of particular articles on the pooled estimates, we performed influence analysis. This method recalculates the pooled prevalence estimate omitting 1 study at a time. We also conducted sensitivity analysis by examining the effect of (1) restricting the analysis to studies conducted in the United States or Canada, (2) restricting the analysis to studies that were conducted in an outpatient setting, and (3) excluding the most heterogeneous studies.

RESULTS

Description of Articles

A total of 515 articles were found through the described search strategy. From these, we retrieved 209 that were relevant for full-text review (Fig 1). Twenty-nine articles met all criteria for inclusion; 14 reported the prevalence of GAS recovered from children who presented with sore throat, 18 reported the prevalence of GAS carriage among asymptomatic patients, and 3 reported both.

Prevalence of GAS Among Children With Sore Throat

There was significant heterogeneity ($P < .001$) among the estimates from the 14 studies that reported data on the prevalence of GAS among children with sore throat (Table 1). On

stratified analysis, prevalence of GAS carriage was lower in studies that included only children who were younger than 5 years as compared with studies that included children of all ages ($P = .026$). Accordingly, we present separate analyses for GAS according to age group (Fig 2).

Only 3 studies provided data on the prevalence of GAS in children who had sore throat and were younger than 5 years (Fig 2). There was no heterogeneity among the estimates ($P = .6$) from these 3 studies, and the pooled prevalence of GAS was 24% (95% CI: 21%–26%).

Fourteen studies presented data on the prevalence of GAS among children of all ages with sore throat. The pooled prevalence of GAS from these studies was 37% (95% CI: 32%–43%). There was substantial heterogeneity among these studies ($P < .001$). To explore the reasons for this heterogeneity, we conducted meta-regression and sensitivity analysis. On meta-regression, there was no association between publication year, study quality, season, country, antibiotic use, laboratory test used to determine streptococcal group, or clinical setting and prevalence estimates. Influence analysis showed that omission of no single study significantly affected the pooled prevalence values. The Galbraith plot identified the populations studied by Dagnelie and Pichichero as the most heterogeneous; however, exclusion of 1 or both of these studies did not significantly alter the results; the prevalence of GAS was 36% (95% CI: 33%–39%) with both studies excluded. Sensitivity analysis revealed that prevalence of GAS was very similar when the analysis was restricted to studies that were conducted in the United States or Canada (37% [95% CI: 31%–43%]). Restricting the analysis to studies that were conducted in an outpatient setting also did not change the estimated significantly (38% [95% CI: 32%–43%).

Prevalence of GAS Carriage Among Asymptomatic Children

Eighteen studies presented data on GAS carriage among asymptomatic children who were younger than 18 years (Table 2). There was significant heterogeneity among the estimates from the studies ($P < .001$).

On stratified analysis, prevalence of GAS carriage was found to be lower in studies that included only children who were younger than 5 years as compared with studies that included children of all ages. Accordingly, we

[a] Cimolai N, Morrison BJ, MacCulloch L, Smith DF, Hlady J. Beta-haemolytic non-group A streptococci and pharyngitis: a case-control study. *Eur J Pediatrics*. 1991;150:776–779

present separate analyses for GAS carriage according to age group (Fig 3).

Only 4 studies provided data on the prevalence of GAS carriage in asymptomatic children who were younger than 5 years. Although there was some remaining heterogeneity among the estimates from these 4 studies ($P = .04$), the small sample of studies did not allow for meaningful meta-regression or sensitivity analysis. The pooled prevalence of GAS from these studies was 3.8% (95% CI: 1%–7%).

Eighteen studies provided data on the prevalence of GAS carriage among children of all ages. The pooled prevalence of GAS carriage in these studies was 12% (95% CI: 9%–14%). There was substantial heterogeneity among these studies ($P < .001$). On meta-regression, none of the variables investigated (see Methods) was associated with the prevalence estimates. Influence analysis showed that omission of no single study significantly changed the pooled prevalence estimates. The Galbraith plot identified the populations studied by Jasir and Pichichero as the most heterogeneous; however, exclusion of 1 or both of these studies did not significantly alter the results; the pooled prevalence with both studies excluded was 11% (95% CI: 9%–13%). Sensitivity analysis revealed that the pooled prevalence was very similar when the analysis was restricted to studies that were conducted in the United States or Canada (11% [95% CI: 7%–15%).

DISCUSSION

This study demonstrates that children who present with sore throat have a high probability of having GAS pharyngitis: 37% of children who presented to an outpatient clinic or emergency department with sore throat were found to have a throat culture that was positive for GAS. The prevalence of GAS in an unselected, office-based adult population has been estimated to be in the range of 5% to 10%.[5] The relatively high probability of GAS disease and acute rheumatic fever in school-aged children, as compared with adults and children who are younger than 5 years, suggests that testing of school-aged children who present with sore throat is beneficial. This is in accordance with the strategies endorsed by the Committee on Infectious Diseases of the American Academy of Pediatrics,[6] the American Heart Association,[7] and the Infectious Disease Society of America.[8]

Only 3 studies provided data on the prevalence of GAS in children who were younger than 5 years and had a sore throat. In those studies, 24% of children who were younger than 5 years and presented with sore throat were positive for GAS; however, because acute rheumatic fever occurs infrequently among preschool children,[9] more data are needed to determine whether routine testing in this age group is justified. It may be the case that presence of other risk factors (eg, age >3 years, older sibling with GAS infection, other signs and symptoms) can be used to select a subgroup of children who have sore throat and would benefit from routine testing.

Twelve percent of children who were older than 5 years were found to be carriers of GAS. This is in agreement with previous epidemiologic studies to date.[10–14] Because it is not possible to distinguish between a child who has a viral infection and is a carrier for GAS and a child who has an acute streptococcal infection and because the prevalence of GAS carriage is relatively high in the school-aged population (~1 in 8), children who have repeated episodes of sore throat and continue to test positive for GAS should be carefully evaluated. Although posttreatment cultures are unnecessary in the majority of patients with GAS pharyngitis,[7] in selected children with recurrent pharyngitis, posttreatment test-

ing may help to differentiate children with true recurrent GAS pharyngitis from carriers; children who are carriers are likely to have persistent GAS even after being treated with appropriate antimicrobial agents.

A somewhat surprising finding was that the prevalence of GAS infection and carriage did not vary significantly among studies that enrolled children only in the winter and those that enrolled children all year. Previous longitudinal studies, which are clearly better at identifying seasonal trends, have convincingly documented that GAS is a seasonal disease. There may be 2 reasons that this seasonality was not observed in our analysis. First, prevalence of GAS was not stratified by season in most of the articles. As such, we could not compare prevalence rates from the winter months with the prevalence rates in the rest of the year. Rather, we compared studies that enrolled children only during the winter with studies that enrolled children all year long. No studies enrolled children during the summer months only. In studies that enrolled children throughout the year, the majority of children were likely to have been enrolled during the winter months; therefore, because of how the data were reported, we were limited in our ability to discern seasonal trends in the data; our data do not conflict with the well-documented seasonality of GAS pharyngitis.

Our analysis had several limitations. The first limitation relates to the paucity of studies with data on children who were younger than 5 years. Additional study on the prevalence of GAS in preschool children is warranted. Second, the heterogeneity among studies could be considered a limitation. We used our clinical judgment and results of the meta-regression analysis to determine when studies were "too different" to be pooled. For example, rather than blindly pooling data from all of the studies, we present data for less heterogeneous subgroups of patients on the basis of age. Much of the remaining heterogeneity is likely attributable to the differences in implicit criteria used by investigators during enrollment. This would have led to differences in the clinical spectrum of patients who were included in various studies. In other words, although all studies met our inclusion criteria, the severity of symptoms of the children enrolled may have varied on the basis of the approach of the investigators or the objectives of the study. Nevertheless, by conducting a comprehensive review of the literature and by using strict a priori inclusion and exclusion criteria, our results provide a more complete picture of GAS prevalence than has previously been reported. Our results were robust to changes in the assumptions tested by sensitivity analyses, and the pooled estimates have relatively narrow CIs.

CONCLUSIONS

This study provides important information for the clinician regarding the expected prevalence of GAS from pharyngeal specimens obtained from children with sore throat and from children who are asymptomatic. The pooled prevalence values presented in this study can be used as an estimate of baseline probability and provide a basis for an evidence-based approach to the treatment of children with this frequently occurring condition.

ACKNOWLEDGMENTS

This study was funded by the Department of Pediatrics, Children's Hospital of Pittsburgh.

Dr Shaikh had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

ON APPEAL FROM THE COURT OF APPEAL FOR MANITOBA

Criminal law — Aggravated assault — Consent — Fraud — Non-disclosure of HIV status — Accused undergoing antiretroviral therapy and having protected and unprotected sexual relations knowing he was HIV-positive — Whether approach outlined in R. v. Cuerrier, 1998 CanLII 796 (SCC), [1998] 2 S.C.R. 371, remains valid in determining whether fraud vitiates consent to sexual relations — Whether non-disclosure of HIV status in circumstances where no realistic possibility of transmission exists can constitute fraud vitiating consent — Criminal Code, R.S.C. 1985, c. C-46, ss. 265(3)(c), 268, 273.

M was charged with nine counts of aggravated sexual assault based on his failure to disclose his HIV-positive status to nine complainants before having sex with them (ss. 265(3)(*c*) and 273 *Cr. C.*). None of the complainants contracted HIV. The trial judge convicted him on six of the counts and acquitted him on the other three, on the basis that sexual intercourse using a condom when viral loads are undetectable does not place a sexual partner at "significant risk of serious bodily harm", as required by *Cuerrier*. The Court of Appeal varied the decision, holding that either low viral loads or condom use could negate significant risk. This reduced to two the

counts on which M could be convicted, and the Court of Appeal entered acquittals on the four remaining counts. The Crown appealed the acquittals.

Held: The appeal should be allowed in part and the convictions in respect of the complaints by S.H., D.C.S. and D.H. should be restored. The appeal should be dismissed in respect of the complaint by K.G.

This Court, in *Cuerrier*, established that failure to disclose that one has HIV may constitute fraud vitiating consent to sexual relations under s. 265(3)(*c*) *Cr. C.* Because HIV poses a risk of serious bodily harm, the operative offence is one of aggravated sexual assault (s. 273 *Cr. C.*). To obtain a conviction under ss. 265(3)(*c*) and 273, the Crown must show, beyond a reasonable doubt, that the complainant's consent to sexual intercourse was vitiated by the accused's fraud as to his HIV status. The test boils down to two elements: (1) *a dishonest act* (either falsehoods or failure to disclose HIV status); and (2) *deprivation* (denying the complainant knowledge which would have caused him or her to refuse sexual relations that exposed him or her to a significant risk of serious bodily harm). Failure to disclose may amount to fraud where the complainant would not have consented had he or she known the accused was HIV-positive, and where sexual contact poses a significant risk of or causes actual serious bodily harm.

Two main criticisms of the *Cuerrier* test have been advanced: first, that it is uncertain, failing to draw a clear line between criminal and non-criminal conduct, and second, that it either overextends the criminal law or confines it too closely — the problem of breadth. While it may be difficult to apply, the *Cuerrier* approach is in principle valid. It carves out an appropriate area for the criminal law — one restricted to "significant risk of serious bodily harm". The test's approach to consent accepts the wisdom of the common law that not every deception that leads to sexual intercourse should be criminalized, while still according consent meaningful scope.

The *Cuerrier* requirement of "significant risk of serious bodily harm" should be read as requiring disclosure of HIV status if there is a realistic possibility of transmission of HIV. This view is supported by the common law and statutory history of fraud vitiating consent to sexual relations, and is in line with *Charter* values of autonomy and equality that respect the interest of a person to choose whether to consent to sex with a particular person or not. It also gives adequate weight to the nature of the harm involved in HIV transmission, and avoids setting the bar for criminal conviction too high or too low. If there is no realistic possibility of transmission of HIV, failure to disclose that one has HIV will not constitute fraud vitiating consent to sexual relations under s. 265(3)(*c*).

The evidence adduced in this case leads to the conclusion that, as a general matter, a realistic possibility of transmission of HIV is negated if: (i) the accused's viral load at the time of sexual relations was low *and* (ii) condom protection was used. This general proposition does not preclude the common law from adapting to future advances in treatment and to circumstances where risk factors other than those considered in this case are at play.

Here, the four complainants all consented to sexual intercourse with M, and testified that they would not have had sex with him had they known he was HIV-positive. M had intercourse by vaginal penetration with the four complainants, during which he ejaculated. At the time of intercourse with the complainants S.H., D.C.S. and D.H., M had a low viral load but did not use a condom. Consequently, those convictions should be maintained. As regards K.G., the record shows that M's viral load was low. When combined with condom protection, this did not expose K.G. to a significant risk of serious bodily harm. This conviction must accordingly be reversed.

The judgment of the Court was delivered by

THE CHIEF JUSTICE —

I. Overview

[1] This case raises the issue of whether an HIV-positive person who engages in sexual relations without disclosing his condition commits aggravated sexual assault.

[2] Sex without consent is sexual assault under s. 265 of the *Criminal Code*, R.S.C. 1985, c. C-46. *R. v. Cuerrier*, 1998 CanLII 796 (SCC), [1998] 2 S.C.R. 371, establishes that failure to advise a partner of one's HIV status may constitute fraud vitiating consent. Because HIV poses a risk of serious bodily harm, the operative offence is one of aggravated sexual assault, attracting a maximum sentence of life imprisonment: *Cuerrier*, at para. 95; ss. 265, 268 and 273 *Cr. C.*

[3] While *Cuerrier* laid down the basic requirements for the offence, the precise circumstances when failure to disclose HIV status vitiates consent and converts sexual activity into a criminal act remain unclear. The parties ask this Court for clarification.

[4] I conclude that a person may be found guilty of aggravated sexual assault under s. 273 of the *Criminal Code* if he fails to disclose HIV-positive status before intercourse and there is a realistic possibility that HIV will be transmitted. If the HIV-positive person has a low viral count as a result of treatment and there is condom protection, the threshold of a realistic possibility of transmission is not met, on the evidence before us.

II. Background

[5] The respondent, Mr. Mabior, lived in Winnipeg. His house was a party place. People came in and out, including a variety of young women. Alcohol and drugs were freely dispensed. From time to time, Mr. Mabior had sex with women who came to his house, including the nine complainants in this case.

[6] Mr. Mabior did not tell the complainants that he was HIV-positive before having sex with them; indeed, he told one of them that he had no STDs. On some occasions, he wore condoms, on others he did not. Sometimes the condoms broke or were removed, and in some cases, the precise nature of the protections taken is unclear. Eight of the nine complainants testified that they would not have consented to sex with Mr. Mabior had they known he was HIV-positive. None of the complainants contracted HIV.

[7] Mr. Mabior was charged with nine counts of aggravated sexual assault (and other related offences), based on his failure to disclose to the complainants that he was HIV-positive. In defence, Mr. Mabior called evidence that he was under treatment, and that he was not infectious or presented only a low risk of infection at the relevant times.

[8] The trial judge convicted Mr. Mabior of six counts of aggravated sexual assault (2008 MBQB 201, 230 Man. R. (2d) 184). She acquitted him on the other three, on the basis that sexual intercourse using a condom when viral loads are undetectable does not place a sexual partner at "significant risk of serious bodily harm", as required by *Cuerrier*.

[9] Mr. Mabior appealed from these six convictions; the Crown did not appeal from the three acquittals. The Manitoba Court of Appeal varied the trial judge's decision, holding that *either* low viral loads *or* condom use could negate significant risk (2010 MBCA 93, 258 Man. R. (2d) 166). This reduced to two the counts on which Mr. Mabior could be convicted, and the Court of Appeal entered acquittals on the four remaining counts. The Crown appeals these acquittals. Mr. Mabior has not cross-appealed against the two convictions upheld by the Court of Appeal.

III. The Legislation

[10] Sections 265 and 273 of the *Criminal Code* provide:

> **265.** (1) A person commits an assault when
>
> (*a*) without the consent of another person, he applies force intentionally to that other person, directly or indirectly;
>
> . . .
>
> (2) This section applies to all forms of assault, including sexual assault . . . and aggravated sexual assault.
>
> (3) For the purposes of this section, no consent is obtained where the complainant submits or does not resist by reason of
>
> . . .
>
> (*c*) fraud;
>
> . . .
>
> **273.** (1) Every one commits an aggravated sexual assault who, in committing a sexual assault, wounds, maims, disfigures or endangers the life of the complainant.
>
> (2) Every person who commits an aggravated sexual assault is guilty of an indictable offence and liable
>
> . . .
>
> (*b*) in any other case, to imprisonment for life.

IV. The Issues

[11] The issues are as follows:

A. What is the correct interpretation of "fraud" vitiating consent to sexual activity in s. 265(3)(*c*) of the *Criminal Code*?

(1) Problems with the existing interpretation of "fraud" vitiating consent:

(a) Uncertainty;

(b) Breadth.

(2) Guides to interpretation:

(a) The purposes of the criminal law;

(b) The common law and statutory history of fraud vitiating consent to sexual relations;

(c) *Charter* values;

(d) The experience of other common law jurisdictions.

(3) Finding a solution:

(a) The active misrepresentation approach;

(b) The absolute disclosure approach;

(c) A case-by-case fact-based approach;

(d) Judicial notice;

(e) Relationship-based distinctions;

(f) The reasonable partner approach;

(g) An evolving common law approach.

(4) Realistic possibility of HIV transmission.

V. Discussion

A. *What is the Correct Interpretation of "Fraud" Vitiating Consent to Sexual Activity in Section 265(3)(c) of the Criminal Code?*

(1) Problems With the Existing Interpretation of "Fraud" Vitiating Consent

[12] This Court considered "fraud" under s. 265(3)(*c*) 14 years ago in *Cuerrier*. The majority test in *Cuerrier* may be stated in different ways, but boils down to two elements: (1) *a dishonest act* (either falsehoods or failure to disclose HIV status); and (2) *deprivation* (denying the complainant knowledge which would have caused her to refuse sexual relations that exposed her to a significant risk of serious bodily harm).

[13] We are invited to revisit the *Cuerrier* test by the parties and by the Manitoba Court of Appeal in this case and the Quebec Court of Appeal in the companion case of *R. v. D.C.*, 2012 SCC 48, [2012] 2 S.C.R. 626. Two main criticisms of the *Cuerrier* test are advanced: first, that it is uncertain, failing to draw a clear line between criminal and non-criminal conduct (uncertainty), and second, that it either overextends the criminal law or confines it too closely — the problem of breadth.

[14] I turn first to the criticism that the *Cuerrier* test is uncertain. It is a fundamental requirement of the rule of law that a person should be able to predict whether a particular act constitutes a crime at the time he commits the act. The rule of law requires that laws provide in advance what can and cannot be done: Lord Bingham, *The Rule of Law* (2010). Condemning people for conduct that they could not have reasonably known was criminal is Kafkaesque and anathema to our notions of justice. After-the-fact condemnation violates the concept of liberty in s. 7 of the *Canadian Charter of Rights and Freedoms* and has no place in the Canadian legal system.

[15] The *Cuerrier* test gives rise to two uncertainties — what constitutes "significant risk" and what constitutes "serious bodily harm"? These terms are broad and different people can and do read them in different ways.

[16] About "significant risk", some people say that virtually any risk of serious bodily harm is significant. Others argue that to be significant, the risk must rise to a higher level. These debates centre on statistical percentages. Is a 1% risk "significant"? Or should it be 10% or 51% or, indeed, .01%? How is a prosecutor to know or a judge decide? And if prosecutors, defence counsel and judges debate the point, how — one may ask — is the ordinary Canadian citizen to know? This uncertainty is compounded by the fact that a host of variables may affect the actual risk of infection.

[17] Debate has also surrounded the requirement that the risk be one of "serious bodily harm". Some sexually transmitted diseases ("STDs") involve little beyond treatable temporary discomfort. Yet even that discomfort, while it persists, may be serious from the perspective of the victim. Other STDs, like HIV, are extremely serious, involving permanent and life-altering symptoms, and in some cases death. Between these two extremes lie many other STDs, some more debilitating than others. Which are sufficiently serious to attract the sanction of the criminal law? *Cuerrier* offers no clear answer.

[18] The uncertainty inherent in the concepts of significant risk and serious bodily harm is compounded by the fact that they are interrelated. The more serious the nature of the harm, the lower the probability of transmission need be to amount to a significant risk of serious bodily harm, it is argued. So it is not simply a matter of percentage of risk and seriousness of the potential disease. It is a matter of the two as they relate to each other.

[19] What emerges is a complex calculus that makes it impossible, in many cases, to predict in advance whether a particular act is criminal under s. 265(3)(*c*) or not. The second major criticism of *Cuerrier* relates to the scope of the conduct it catches. The danger of an overbroad interpretation is the criminalization of conduct that does not present the level of moral culpability and potential harm to others appropriate to the ultimate sanction of the criminal law. A criminal conviction and imprisonment, with the attendant stigma that attaches, is the most serious sanction the law can impose on a person, and is generally reserved for conduct that is highly culpable — conduct that is viewed as harmful to society, reprehensible and unacceptable. It requires both a culpable act — *actus reus* — and a guilty mind — *mens rea* — the parameters of which should be clearly delineated by the law.

(2) Guides to Interpretation

[20] As for all issues of statutory interpretation, the basic question is what Parliament intended. That intention is discovered by looking at the words of the provision, informed by its history, context and purpose.

[21] The words of s. 265(3)(*c*) do not on their face reveal much about how Parliament intended "fraud" to be interpreted. The concept was taken by Parliament from the common law.

[22] The interpretation of "fraud" vitiating consent to sexual relations is informed by four considerations: (a) the purposes of the criminal law; (b) the common law and statutory history of the concept; (c) *Charter* values, particularly equality, autonomy, liberty, privacy and human dignity; and (d) the experience of other common law jurisdictions. I will consider each in turn.

(a) *The Purposes of the Criminal Law*

[23] The interpretation of fraud vitiating consent to sexual relations should further the purposes of the criminal law, notably identifying, deterring and punishing criminal conduct, defined by a wrongful act and guilty mind. Morality infuses the criminal law. But the law does not seek to criminalize all immorality. The principal objective of the criminal law is the public identification of wrongdoing *qua* wrongdoing which violates public order and is so blameworthy that it deserves penal sanction: *Proprietary Articles Trade Association v. Attorney-General for Canada*, 1931 CanLII 385 (UK JCPC), [1931] A.C. 310 (P.C.); *Reference re Validity of Section 5(a) of the Dairy Industry Act*, 1948 CanLII 2 (SCC), [1949] S.C.R. 1, aff'd 1950 CanLII 342 (UK JCPC), [1951] A.C. 179 (P.C.); *Lord's Day Alliance of Canada v. Attorney General of British Columbia*, 1959 CanLII 42 (SCC), [1959] S.C.R. 497; *The Queen v. Sault Ste. Marie*, 1978 CanLII 11 (SCC), [1978] 2 S.C.R. 1299; *Boggs v. The Queen*, 1981 CanLII 39 (SCC), [1981] 1 S.C.R. 49; *Skoke-Graham v. The Queen*, 1985 CanLII 60 (SCC), [1985] 1 S.C.R. 106.

[24] The law draws a sharp distinction between civil wrongdoing and criminal wrongdoing. Criminal conduct requires both a wrongful act and a guilty mind. It requires "a significant fault element": *R. v. Roy*, 2012 SCC 26, [2012] 2 S.C.R. 60, at para. 32. As Charron J. stated for the majority of this Court in *R. v. Beatty*, 2008 SCC 5, [2008] 1 S.C.R. 49, at para. 34:

> If every departure from the civil norm is to be criminalized, regardless of the degree, we risk casting the net too widely and branding as criminals persons who are in reality not morally blameworthy. Such an approach risks violating the principle of fundamental justice that the morally innocent not be deprived of liberty.

The potential consequences of a conviction for aggravated sexual assault — up to life imprisonment — underline the importance of insisting on moral blameworthiness in the interpretation of s. 265(3)(*c*) of the *Criminal Code*.

(b) *The Common Law and Statutory History of Fraud Vitiating Consent to Sexual Relations*

[25] The common law history of fraud vitiating consent to sexual relations reveals three periods. The early cases support the view that failure to disclose to a partner the fact that one has a serious sexually transmitted disease could constitute fraud vitiating consent to sexual relations, resulting in convictions for rape or assault. This was reversed in *The Queen v. Clarence* (1888), 22 Q.B.D. 23 (Cr. Cas. Res.), which held that fraud was confined to deception as to the sexual nature of the act or as to the identity of the male sexual partner. In the post-*Charter* era, a return to a broader view of fraud vitiating consent is appropriate.

[26] The first recorded cases to look at the problem before us took a generous approach to consent to sexual intercourse — one that accepted that sexual partners (always women in those days) were entitled to refuse sexual intercourse and should not be tricked into it by deceit. The courts adopted a flexible approach to "fraud" vitiating consent to sexual relations. Without attempting to define the term, they showed themselves willing to extend the term to fundamental aspects of sexual intercourse.

[27] For example, in *R. v. Flattery* (1877), 13 Cox C.C. 388 (C.C.A.), a conviction of rape was upheld for a man operating a booth at a fair who had obtained sex from a girl of 19 on the pretext of medical treatment. It was held that the victim's consent to physical contact with the accused was vitiated by his fraud, because she had only consented to a surgical operation, and not to a sexual act.

[28] Similarly, early common law cases accepted that impersonation of the spouse — falsely pretending to be the victim's husband — could constitute fraud vitiating consent. In *R. v. Dee* (1884), 15 Cox C.C. 579 (Cr. Cas. Res. Ir.), O'Brien J. left no doubt on this issue:

> That brings us back to the question which in law is the crime of rape. The crime is the invasion of a woman's person without her consent, and I see no real difference between the want of consent and the act being against her will, which is the language of the indictment, though the distinction is taken by Lord Campbell, or between the negation of consent and positive dissent. Whether the act of consent be the result of overpowering force, or of fear, or of incapacity, or of natural condition, or of deception, it is still want of consent, and the consent must be, not consent to the act, but to the act of the particular person — not in the abstract, but in the concrete . . . . [p. 598]

[29] In *R. v. Bennett* (1866), 4 F. & F. 1105, 176 E.R. 925 (West. Cir.), similar reasoning was applied to hold that concealment of venereal disease amounted to fraud vitiating consent:

> An assault is within the rule that fraud vitiates consent, and therefore, if the prisoner, knowing that he had a foul disease, induced his niece to sleep with him, intending to possess her, and infected her, she being ignorant of his condition, any consent, which she may have given, would be vitiated, and the prisoner would be guilty of an indecent assault. [p. 925]

[30] Again in *R. v. Sinclair* (1867), 13 Cox C.C. 28, the Central Criminal Court found fraud vitiating consent for non-disclosure of gonorrhœa, stating that if the complainant "would not have consented if she had known the fact, then her consent is vitiated by the deceit practised upon her, and the prisoner would be guilty of an assault" (p. 29).

[31] These cases evinced a generous approach to the issue of consent and when deceit might vitiate it, an approach that respected the right of the women involved to choose whether to have intercourse or not. However, this jurisprudence was shortly to be set aside, in a series of cases which culminated in *Clarence*. To read these cases is to enter a world foreign to modern sensitivities — the world of Victorian morality.

[32] The case that announced the change was *Hegarty v. Shine* (1878), 14 Cox C.C. 124 (H.C.J. Ir. (Q.B.D.)), a civil case involving an action for assault. Mr. Shine, the master of the house, had sexual relations with his domestic servant over a period of two years. She became pregnant and had a child. Both she and the child were infected with syphilis. The court dismissed the action against Mr. Shine on the basis of *ex turpi causa non oritur actio* — the plaintiff was the victim of her own immoral act, which the law could not condone. On the matter of fraud, the majority stated that the doctrine of fraud was confined to *mistake as to whether the act was sexual or not*: "In the case before us the defendant actively consented to the very thing, that is to say, sexual intercourse, with full knowledge and experience of the nature of the act" (p. 130). The appeal court ((1878), 14 Cox C.C. 145) confirmed that only deceit as to the nature of the act could vitiate consent. The court emphasized the pitiable condition of the victim, but concluded the law could not assist her.

[33] The point of no return for the earlier, more open view of fraud was reached in *Clarence*. That case confirmed that fraud could vitiate consent to sexual relations only if the complainant was deceived as to the *sexual nature* of the act or as to the identity of the man. The facts were simple. The couple were married. The husband did not tell his wife he had gonorrhœa and infected her. The husband was charged with assault and unlawful infliction of bodily harm.

[34] The fact that 13 judges sat suggests the case was viewed as important. The court divided nine to four, and the husband was acquitted. The majority held that fraud in the context of sexual relations had been interpreted too broadly by the earlier cases, and that it was necessary to limit its application to situations where the complainant was deceived as to the sexual nature of the act or as to the identity of the man. This produced a rule that was to prevail for almost 100 years that fraud could not vitiate consent to sexual intercourse unless it went to the "sexual nature of the act" or to the identity of the sexual partner.

[35] The opinion of Stephen J. encapsulates the view of the majority in *Clarence*. Stephen J. found that the offence of unlawful infliction of bodily harm could not apply to the case. While the act posed by the husband was indeed unlawful — infecting one's wife was forbidden by the law relating to marriage since it constituted cruelty and could be evidence of adultery —, it could not be said that it constituted infliction of bodily harm. Indeed, the words "infliction of bodily harm" were construed as requiring a physical assault. Stephen J. found that infecting a person with a disease did not constitute such an assault.

[36] Stephen J. went on to consider the question of obtaining sexual relations by fraud. He expressed the view that the only fraud capable of vitiating consent to sexual relations was fraud as to the nature of the act of intercourse, or as to the identity of the sexual partner. If the victim knew the act was sexual, and was not deceived as to the identity of her partner, she could not complain that she had been deceived and her "consent" fraudulently obtained. Stephen J. commented briefly that neither *Bennett* nor *Sinclair* could be relied upon as precedent.

[37] The reasons of Pollock B., also in the majority, added that sexual acts done by a husband to his wife cannot be unlawful (pp. 63-64). The husband possessed conjugal rights over his wife to which she had consented by marrying him. Once married, the wife had no right to refuse her husband's demands. Since sexual acts between spouses were lawful, Pollock B. reasoned, all such acts done by a husband — including those characterized by cruelty — must be lawful.

[38] The *Clarence* test was accepted throughout the common law world and prevailed until recent times. The strictness with which it was applied is illustrated by a 1957 decision of the Australian High Court, *Papadimitropoulos v. The Queen* (1957), 98 C.L.R. 249. The accused had induced the complainant to have sexual intercourse by duping her into believing that they were legally married. He was acquitted of the charge of rape. The court summed up the law as follows:

> To say that in having intercourse with him she supposed that she was concerned in a perfectly moral act is not to say that the intercourse was without her consent. To return to the central point; rape is carnal knowledge of a woman without her consent: carnal knowledge is the physical fact of penetration; it is the consent to that which is in question; such a consent demands a perception as to what is about to take place, as to the identity of the man and the character of what he is doing. But once the consent is comprehending and actual the inducing causes cannot destroy its reality and leave the man guilty of rape. [Emphasis added; p. 261.]

[39] The views of the majority in *Clarence* were reflected in the first Canadian *Criminal Code* in 1892 (S.C. 1892, c. 29). Parliament defined fraud for purposes of rape and indecent assault narrowly, by restricting it to "false and fraudulent representations as to the nature and quality of the act": ss. 259(*b*) and 266. The *Code* thus incorporated the concerns of the majority in *Clarence*. The deceitful act was limited to "false and fraudulent representations" by opposition to simple concealment, and the subject of the fraud was limited to the "nature and quality of the act". As a consequence, Canadian courts accepted *Clarence* as settled law and continued to hold that only active fraud as to the nature of the act, i.e. fraud as to its sexual character, or as to the identity of one's sexual partner constituted fraud vitiating consent to sexual intercourse: see, e.g., *R. v. Harms* (1943), 1943 CanLII 146 (SK CA), 81 C.C.C. 4 (Sask. C.A.); *Bolduc v. The Queen*, 1967 CanLII 57 (SCC), [1967] S.C.R. 677.

[40] In 1983, Parliament amended the *Criminal Code* to create the present s. 265(3)(*c*): S.C. 1980-81-82-83, c. 125, s. 19. This amendment was part of a major overhaul of the law of sexual offences which aimed, *inter alia*, at protecting the integrity of the person and eliminating sexual discrimination in the criminal law. The new provision referred simply to "fraud", dropping the qualifying phrases "false and fraudulent representations" and "nature and quality of the act". Arguably, this change evidenced Parliament's intent that "fraud" should be read more broadly than it had been in the past. However, courts continued to apply a restrictive interpretation to the term: see *R. v. Petrozzi* (1987), 1987 CanLII 2786 (BC CA), 35 C.C.C. (3d) 528 (B.C.C.A.); *R. v. Lee* (1991), 1991 CanLII 7351 (ON SC), 3 O.R. (3d) 726 (Gen. Div.); *R. v. Ssenyonga* (1993), 1993 CanLII 14680 (ON SC), 81 C.C.C. (3d) 257 (Ont. Ct. (Gen. Div.)).

[41] Occasionally, a more generous approach surfaced as to when fraud could vitiate consent to sexual relations. For instance, American caselaw was more inclined to convict the accused of assault or rape on facts similar to those in *Clarence*: *State v. Marcks*, 41 S.W. 973 (Miss. 1897), at p. 973, and 43 S.W. 1095 (1898), at pp. 1097-98; *State v. Lankford*, 102 A. 63 (Del. Ct. Gen. Sess. 1917), at p. 64; *United States v. Johnson*, 27 M.J. 798 (A.F.C.M.R. 1988), at p. 804; *United States v. Dumford*, 28 M.J. 836 (A.F.C.M.R. 1989), at p. 839. And in Canada, in *R. v. Maurantonio*, 1967 CanLII 317 (ON CA), [1968] 1 O.R. 145 (C.A.), Hartt J. (*ad hoc*) held that "the words 'nature and quality of the act' . . . should not be so narrowly construed as to include only the physical action but rather must be interpreted to encompass those concomitant circumstances which give meaning to the particular physical activity in question" (p. 153). But these were minority voices.

[42] There are not many cases on the books, to be sure. One understands why when one considers the practical implications of the *Clarence* test. The cases where a woman consents to sex but thinks it is *not* sex or that it is sex with a different man are necessarily rare. Submitting to a medical examination only to discover it is a sexual encounter might be such a case; the complainant does not consent to the sexual act but to a medical procedure. Under *Clarence* and its progeny, if the woman consented to the sexual act with the given man, no matter what the deceit, the man could not be convicted for his act. It is not surprising that the legal lexicon contains few

cases dealing with fraud vitiating consent. The stark fact was that in all but rare cases fraud could not vitiate consent.

[43] Canadian common law on fraud vitiating consent to sexual relations has now entered a third, post-*Clarence* era. *Charter* values of equality, autonomy, liberty, privacy and human dignity require full recognition of the right to consent or to withhold consent to sexual relations. Fraud under s. 265(3)(*c*) must be interpreted with these values in mind. The *Clarence* line of jurisprudence, which confined fraud to the question of whether the complainant knew the act was sexual or not, is no longer appropriate in the Canadian context. To hold that a complainant consents to the risk of an undisclosed serious disease because he or she knew the act was sexual affronts contemporary sensibilities and contemporary constitutional values.

(c) *Charter Values*

[44] Courts must interpret legislation harmoniously with the constitutional norms enshrined in the *Charter*: *R. v. Sharpe*, 2001 SCC 2, [2001] 1 S.C.R. 45, at para. 33; *Application under s. 83.28 of the Criminal Code (Re)*, 2004 SCC 42, [2004] 2 S.C.R. 248, at para. 35. *Charter* values are always relevant to the interpretation of a disputed provision of the *Criminal Code*.

[45] The *Charter* values of equality, autonomy, liberty, privacy and human dignity are particularly relevant to the interpretation of fraud vitiating consent to sexual relations. The formerly narrow view of consent has been replaced by a view that respects each sexual partner as an autonomous, equal and free person. Our modern understanding of sexual assault is based on the preservation of the right to refuse sexual intercourse: sexual assault is wrong because it denies the victim's dignity as a human being. Fraud in s. 265(3)(*c*) of the *Criminal Code* must be interpreted in light of these values.

[46] As we have already seen, prior to the adoption of the *Charter* in 1982 and the reform of sexual offences in 1983, courts took a restrictive view of how lack of consent to sexual relations could be established and how consent could be negated by fraud. Rules of evidence and procedure, like the ancient rule that non-consent must be supported by evidence of a "hue and cry" in the neighbourhood immediately after the alleged sexual assault, or the willingness of judges to infer consent from dress or prior sexual experience, systemically biased the trial process in favour of finding consent. In like fashion, the jurisprudence, post-*Clarence*, took a narrow view of fraud capable of vitiating consent, holding that it went only to the sexual nature of the act, and that it did not apply to married women, who were bound to submit to their husbands in all circumstances.

[47] Post-*Charter* Canadian law has repudiated this crabbed view of consent and fraud. Amendments to the *Criminal Code* have removed the evidentiary burdens and presumptions that once made proof of lack of consent difficult. Courts have held that judges may not infer consent from the way the complainant was dressed or the fact that she may have flirted: *R. v. Ewanchuk*, 1999 CanLII 711 (SCC), [1999] 1 S.C.R. 330. And in 1998, *Cuerrier* signaled a return to a generous interpretation of fraud capable of vitiating consent.

[48] In keeping with the *Charter* values of equality and autonomy, we now see sexual assault not only as a crime associated with emotional and physical harm to the victim, but as the wrongful exploitation of another human being. To engage in sexual acts without the consent of another person is to treat him or her as an object and negate his or her human dignity. Although the *Charter* is not directly engaged, the values that animate it must be taken into account in interpreting s. 265(3)(*c*) of the *Criminal Code*.

(d) *The Experience of Other Common Law Jurisdictions*

[49] The parties and a number of interveners have relied on the approach of foreign legal systems to support their positions.

[50] A survey of comparative law shows that common law jurisdictions criminalize the *actual sexual transmission* of HIV, when the HIV-positive person is aware of his or her serologic status and when the partner does not give informed consent to the risk of infection. Several jurisdictions treat transmission of HIV following non-disclosure as offences involving bodily harm, rather than as sexual offences. Such transmission has been prosecuted on the following legal grounds: in England, for reckless infliction of bodily injury, under s. 20 of *The Offences against the Person Act, 1861*, 24 & 25 Vict., c. 100; in the Australian state of Victoria, for "[c]onduct

endangering life" (s. 22 of the *Crimes Act 1958* (Vic.)); and in New Zealand, for, *inter alia*, "reckless disregard for the safety of others" that "causes grievous bodily harm" (s. 188(2) of the *Crimes Act 1961*, No. 43). See I. Grant, "The Prosecution of Non-disclosure of HIV in Canada: Time to Rethink *Cuerrier*" (2011), 5 *M.J.L.H.* 7, at pp. 31-41.

[51] However, deception that exposes a partner to a *risk of transmission* — but that does not ultimately result in transmission — is not criminalized in many jurisdictions. In England, exposing one's partner to HIV without advising of HIV status does not vitiate consent. Fraud vitiates consent only if it goes to "the nature or purpose of the relevant act", which excludes deception as to HIV status: *R. v. B.*, [2006] EWCA Crim 2945, [2007] 1 W.L.R. 1567, at para. 12. Theoretically, s. 18 of *The Offences against the Person Act, 1861*, which criminalizes intentional infliction of harm, could be used in England to punish non-disclosure of HIV-positive status as a form of *attempted* intentional infliction of harm. However, the high evidentiary burden "of proving that someone actually intended to transmit HIV through sex (as opposed to intending to have unprotected sex)" places a prohibitive onus on the Crown (Grant, at p. 32).

[52] In Australia, six of the nine jurisdictions do not criminalize exposure absent transmission. Of the three jurisdictions that criminalize exposure to a risk of transmission (*Crimes Act 1958* (Vic.), ss. 22 and 23; *Criminal Law Consolidation Act 1935* (S.A.), s. 29; *Criminal Code Act* (N.T.), ss. 174C and 174D), two (Victoria and the Northern Territory) apply lesser criminal offences for cases where no actual transmission resulted from exposure.

[53] In New Zealand, liability hinges, *inter alia*, on whether transmission occurs. Absent transmission, the failure to disclose HIV-positive status prior to sexual relations attracts the lesser offence of criminal nuisance (s. 145 of the *Crimes Act 1961*; *R. v. Mwai*, [1995] 3 N.Z.L.R. 149 (C.A.)).

[54] Professor Grant summarizes the contrast between the Canadian approach and the approach taken by England, Australia and New Zealand as follows:

> In Canada, the same charge of aggravated (sexual) assault is typically used regardless of the nature of the deception, whether the virus is transmitted, or whether there is an isolated incident of non-disclosure or an ongoing course of non-disclosure. . . . In all other jurisdictions [canvassed in this study], the offence is characterized as the infliction of bodily harm, and not as non-consensual sexual contact. [p. 42]

[55] In sum, while the experience of other jurisdictions is not conclusive, it sounds a note of caution against extending the criminal law beyond its appropriate reach in this complex and emerging area of the law.

(3) Finding a Solution

[56] We have discussed the need for a clear and appropriately tailored test for fraud vitiating consent in s. 265(3)(*c*) of the *Criminal Code*, in the context of failure to disclose HIV-positive status. With a view to meeting that need, we have canvassed four guides to construing the provision — the proper ambit of the criminal law, the common law and statutory background of the concept of fraud, *Charter* values and the approach to non-disclosure of HIV status adopted in other countries. This brings us to the nub of the question before us — when, precisely, should non-disclosure of HIV status amount to fraud vitiating consent under s. 265(3)(*c*)?

[57] The four interpretational considerations suggest that the *Cuerrier* test is valid from the perspective of principle and impact. The *Cuerrier* test, to recap, requires proof of two elements: (1) a dishonest act; and (2) deprivation. It defines the first element broadly in terms of either misrepresentation or non-disclosure of HIV, and the second element equally broadly in terms of whether the act poses a "significant risk of serious bodily harm".

[58] While it may be difficult to apply, the *Cuerrier* approach is in principle valid. It carves out an appropriate area for the criminal law — one restricted to "significant risk of serious bodily harm". It reflects the *Charter* values of autonomy, liberty and equality, and the evolution of the common law, appropriately excluding the *Clarence* line of authority. The test's approach to consent accepts the wisdom of the common law that not every deception that leads to sexual intercourse should be criminalized, while still according consent meaningful scope.

While *Cuerrier* takes the criminal law further than courts in other common law jurisdictions have, it can be argued other courts have not gone far enough: see L. H. Leigh, "Two cases on consent in rape" (2007), 5 *Arch. News* 6.

[59] Some interveners challenge the use of the criminal law in the case of HIV on the ground that it may deter people from seeking treatment or disclosing their condition, thereby increasing the health risk to the carrier and those he has sex with. On the record before us, I cannot accept this argument. The only "evidence" was studies presented by interveners suggesting that criminalization "probably" acts as a deterrent to HIV testing: see, e.g., M. A. Wainberg, "Criminalizing HIV transmission may be a mistake" (2009), 180 *C.M.A.J.* 688. Other studies suggest little difference in reporting rates in states that criminalized and did not criminalize behaviour: S. Burris, et al., "Do Criminal Laws Influence HIV Risk Behavior? An Empirical Trial" (2007), 39 *Ariz. St. L.J.* 467, at p. 501. The conclusions in these studies are tentative, and the studies were not placed in evidence and not tested by cross-examination. They fail to provide an adequate basis to justify judicial reversal of the accepted place of the criminal law in this domain.

[60] It follows that *Cuerrier* should not be jettisoned. The problems of uncertainty and appropriate reach that have emerged in its application should be addressed, but to the extent possible within the general framework of *Cuerrier*. This brings us to the suggestions for dealing with the problems of uncertainty and overbreadth that have arisen in applying *Cuerrier*.

(a) *The Active Misrepresentation Approach*

[61] It is argued that one way to correct the uncertainty and reach problems in *Cuerrier*'s application is to narrow the concept of dishonest act to active deception — a clear misrepresentation or a lie in response to a clear question.

[62] This approach would go a long way to remedying the problem of uncertainty. A person would know that unless they made a positive misrepresentation or lied in response to a clear question, they would not be committing a crime. And it would also remedy the perceived problem of overbreadth; the narrower definition of fraud would prevent those who may inadvertently or negligently fail to disclose HIV status from being criminalized.

[63] This approach has some support. My concurring reasons in *Cuerrier* defined fraud as arising when "the person represents that he or she is disease-free" (para. 72, Gonthier J. concurring). This "active deception" approach has been viewed favourably by some: see Leigh, at p. 7.

[64] The approach, however, also suffers from difficulties. The first is that it may be difficult to distinguish between active deception and passive deception by non-disclosure. Everything depends on the circumstances. This approach's sensitivity to context blurs the line between criminal and non-criminal conduct. Conversations leading up to sexual acts are not always models of clarity. People tend not to use precise language. Gestures may supplant language. For example, is the shake of the head in response to a partner's question about HIV a positive representation that one does not have HIV? Moreover, there may be circumstances where the partner may reasonably infer absence of disease from prior conversations or circumstances. To be sure, trial judges can untangle complicated fact situations and decide if there has been a positive misrepresentation. But the fact remains that this marker may not fully or fairly capture the deception that underlies a particular fraud, and may be a difficult test to apply in practice.

[65] Second, there is arguably no principled distinction between active deception and passive deception. Should the trusting wife who does not ask a direct question as to HIV status of her partner be placed in a worse position than the casual date who does? The point from the complainant's perspective is that in either case she would not have given her consent had the deception not occurred. Fraud is fraud, whether induced by blatant lies or sly deceit.

(b) *The Absolute Disclosure Approach*

[66] The Crown submits that all HIV-positive people should be required to disclose the fact to all sexual partners in all cases. This amounts to removing the "significant risk of serious bodily harm" requirement from the second element of the *Cuerrier* test.

[67] This approach provides a clear test, solving the problem of uncertainty. However, its solution to the problem of breadth is less convincing. This approach arguably casts the net of criminal culpability too widely. People who act responsibly and whose conduct causes no harm and indeed may pose no risk of harm, could find themselves criminalized and imprisoned for lengthy periods. Moreover, this approach seems to expand fraud vitiating consent in s. 265(3)(*c*) further than necessary, by defining it as simple dishonesty and effectively eliminating the deprivation element of fraud. Finally, this absolute approach is arguably unfair and stigmatizing to people with HIV, an already vulnerable group. Provided people so afflicted act responsibly and pose no risk of harm to others, they should not be put to the choice of disclosing their disease or facing criminalization.

(c) *A Case-by-Case Fact-based Approach*

[68] The respondent argues that the *Cuerrier* "significant risk of serious bodily harm" test remains a workable test, but seeks to clarify it by emphasizing that it is simply a statement of what the evidence must establish to support a finding of fraud under s. 265(3)(*c*). A "significant risk of serious bodily harm" must be established by medical evidence in each case. The question is whether at the time of the sexual act in question, the particular act posed a significant risk of transmitting HIV. This typically requires the Crown to call expert evidence as to the accused's viral count at the time of the offence as well as risks associated with any condom protection used. The trial judge must be satisfied that the evidence establishes beyond a reasonable doubt that the accused's conduct at the moment of the offence posed a significant risk of serious bodily harm. Any doubt must be resolved in favour of the accused.

[69] While respectful of the rights of accused persons, this approach does not remedy the problems of uncertainty and reach that make *Cuerrier* difficult to apply. The process would be onerous. In every case, medical experts would have to be called. Lengthy examination and cross-examination would have to take place. Trial judges would have to spend long hours assessing the evidence to determine if it establishes a "significant risk of serious bodily harm" at the time of the alleged offence. Finally, the risk of conflicting judgments could render the process unfair from a systemic standpoint. The court of appeal, while accepting the trial judge's conclusions on the evidence, might take a different view on the mixed question of fact and law of whether the risk was "significant". Years may pass in legal no-man's-land with no one knowing whether the accused is guilty or not guilty. Enormous costs, both for the prosecution and the defence, would be run up. This case illustrates all these problems.

(d) *Judicial Notice of the Effect of Condom Use*

[70] To mitigate the uncertainties of the fact-based *Cuerrier* test, the respondent suggests that courts can take judicial notice of the fact that condom use always negates a significant risk of serious bodily harm.

[71] Before a judge can take judicial notice of a fact, the fact must be shown to be so "notorious" or in modern parlance, "accepted", that no reasonable person would dispute it: *R. v. Find*, 2001 SCC 32, [2001] 1 S.C.R. 863, at para. 48; *R. v. Spence*, 2005 SCC 71, [2005] 3 S.C.R. 458, at para. 53. Yet the record here is replete with debate about whether use of a condom alone negates significant risk of serious bodily harm, and the controversy is exacerbated by the rapidly changing state of the science and by the fact-specific nature of risk. Judicial notice is not available here and cannot form the basis for formulating general propositions relating to the factual issue of risk, in the absence of indisputable consensus.

(e) *Relationship-based Distinctions*

[72] Another way of narrowing the *Cuerrier* "significant risk of serious bodily harm" approach to fraud under s. 265(3)(*c*) is to confine it to special relationships. It has been suggested in the commercial context that failure to disclose may amount to fraud when parties have a relationship of trust, quasi-trust or confidence: B. L. Nightingale, *The Law of Fraud and Related Offences* (loose-leaf). The distinction could conceivably be extended to relationships where one party is vulnerable, like the young often intoxicated women who had sex with Mr. Mabior in this case. This approach assumes that sexual partners who do not ask about STDs bear a risk of exposing themselves to HIV, unless a relationship of trust exists between them.

[73] The law of fraud in commercial situations provides some support for this approach. Originally, the common law and courts of equity did not regard mere silence, standing on its own without some other form of

conduct which induced a false belief in another, as being fraudulent: *Twining v. Morrice* (1788), 2 Bro. C.C. 326, 29 E.R. 182; *Conolly v. Parsons* (1797), 3 Ves. 625n (Ch.); *Walters v. Morgan* (1861), 3 De G. F. & J. 718, 45 E.R. 1056. However, over time, equity recognized specific circumstances warranting a positive duty to disclose material facts, including a relationship of trust, quasi-trust or confidence.

[74] Against this approach, it can be argued that it narrows "fraud" under s. 265(3)(*c*) too much. Is there a good reason for compelling disclosure to one's wife but not to a casual date? Where the concern is the contraction of a life-altering disease, the answer is no.

[75] Historically, fraud capable of vitiating consent to sexual intercourse has not followed the patterns of commercial fraud. The special context of sexual fraud raises unique concerns. This has generally resulted in a narrower approach to fraud, marked by its own peculiar considerations. The relationship between the parties in a particular case has tended not to figure among them. The closest the law has come to a relationship-based approach are the suggestions in Victorian times that wives and prostitutes — for different reasons relating to the mores of the time — could never assert fraud vitiating consent to sexual intercourse: see *Clarence*. Such ideas strike the modern ear, attuned to equality, as offensive.

(f) *The Reasonable Partner Approach*

[76] Yet another possibility is to define "fraud" under s. 265(3)(*c*) as what a reasonable and informed person in the position of the HIV-positive person's potential partner would expect. The test would be objective, but based on the circumstances of the particular case, including the type of relationship the parties had.

[77] This approach has the advantage of taking into account the expectations of the parties as they existed on the facts of the case. In this sense, it is fairer than a test that is based on a general norm presumed to apply in all cases. An HIV-positive person may be expected to understand the expectations of his partner in the particular circumstances at hand, and act accordingly.

[78] This approach also recognizes that allocation of responsibility for protecting against transmission of sexual diseases may vary with relationships and with the passage of time. One of the historic difficulties in formulating a test for fraud vitiating consent to sexual relations has been the variation in social norms and expectations over time. In Victorian times, husbands were held to be incapable of committing fraud vitiating consent, since wives had no right to refuse consent to sexual intercourse with their husbands. In more recent times, some argue that expectations have shifted from the view that an infected person bears all the responsibility for the sexual health of both partners, to the view that each party is responsible for his or her own sexual health. A contextually grounded reasonableness approach would avoid these problems by tailoring the result to the relationship from which the criminal charge arises.

[79] Again, however, the approach can be criticized. The most telling criticism is that it does not lay down a clear test for fraud, leaving people uncertain as to where the line lies between criminal conduct and non-criminal conduct. Unless the partners have themselves established the lines, the HIV-positive person is left to infer from the nature of the relationship what his potential partner, acting reasonably, would expect.

[80] This leads to a second criticism — overreach of the criminal law, and its correlative, unfairness to the accused. In the heat and anticipation of the sexual moment, assessments of what a reasonable partner would expect may be mistaken. Is the person then to be criminalized and sent to prison for perhaps years, for what is at its base the result of misjudgment? Such may be the consequence of the reasonable partner expectation test.

(g) *An Evolving Common Law Approach*

[81] This leaves the option of building greater certainty into the *Cuerrier* test by indicating when the significant risk test is met in terms of principle and concrete situations. Such an approach is consistent with the incremental role of common law courts in adapting the contours of an offence to the requirements of justice and practical application.

[82] The question, building on *Cuerrier*, is: when do sexual relations with an HIV-positive person pose a "significant risk of serious bodily harm"? In answering this question, the facts as found by the trial judge

should be accepted, absent palpable and overriding error. Whether those facts establish a "significant risk of serious bodily harm" is a question of law: see C.A., at para. 37. The terms "serious bodily harm" mean "any hurt or injury, whether physical or psychological, that interferes in a substantial way with the integrity, health or well-being of a victim": *R. v. McCraw*, 1991 CanLII 29 (SCC), [1991] 3 S.C.R. 72, at p. 88. Of course, actual transmission of HIV constitutes serious bodily harm.

[83] The courts below answered this question of law differently. The trial judge took the approach that any risk of transmission of HIV, however small, constitutes "significant risk of serious bodily harm" (see reference to the trial judge's reasons, at C.A. para. 66). The Court of Appeal, by contrast, held that "significant risk" connoted a high risk of transmission of HIV. In its view "significant risk of serious bodily harm" under *Cuerrier* requires a "significant or high risk" (para. 80) — the "opposite of evidence of a 'high probability' of no infectiousness" (para. 127).

[84] In my view, a "significant risk of serious bodily harm" connotes a position between the extremes of no risk (the trial judge's test) and "high risk" (the Court of Appeal's test). Where there is a *realistic possibility of transmission of HIV*, a significant risk of serious bodily harm is established, and the deprivation element of the *Cuerrier* test is met. This approach is supported by the following considerations.

[85] First, "significant risk of serious bodily harm" cannot mean any risk, however small. That would come down to adopting the absolute disclosure approach, with its numerous shortcomings, and would effectively read the word "significant" out of the *Cuerrier* test.

[86] Second, a standard of "high" risk does not give adequate weight to the nature of the harm involved in HIV transmission. "Significant risk" in *Cuerrier* is informed both by the risk of contraction of HIV and the seriousness of the disease if contracted. These factors vary inversely. The more serious the nature of the harm, the lower the probability of transmission need be to amount to a "significant risk of serious bodily harm".

[87] Third, as discussed earlier in considering guides to interpretation, a standard of realistic possibility of transmission of HIV avoids setting the bar for criminal conviction too high or too low. A standard of any risk, however small, would arguably set the threshold for criminal conduct too low. On the other hand, to limit s. 265(3)(*c*) to cases where the risk is "high" might condone irresponsible, reprehensible conduct.

[88] Fourth, the common law and statutory history of fraud vitiating consent to sexual relations supports viewing "significant risk of serious bodily harm" as requiring a realistic possibility of transmission of HIV. This history suggests that only serious deceptions with serious consequences are capable of vitiating consent to sexual relations. Interpreting "significant risk of serious bodily harm" in *Cuerrier* as extending to any risk of transmission would be inconsistent with this. A realistic possibility of transmission arguably strikes the right balance for a disease with the life-altering consequences of HIV.

[89] Fifth, the values of autonomy and equality enshrined in the *Charter* support an approach to fraud vitiating consent that respects the interest of a person to choose whether to consent to sex with a particular person or not. The law must strike a balance between this interest and the need to confine the criminal law to conduct associated with serious wrongs and serious harms. Drawing the line between criminal and non-criminal misconduct at a realistic possibility of transmission arguably strikes an appropriate balance between the complainant's interest in autonomy and equality and the need to prevent over-extension of criminal sanctions.

[90] Finally, interpreting "significant risk of serious bodily harm" as entailing a realistic possibility of transmission of HIV is supported by a number of cases. Apart from the trial reasons in this case, we have been referred to no case holding that "significant" means any risk, however small. To be sure, not many cases have considered the point. But the few that have are worth noting. In *R. v. Jones*, 2002 NBQB 340, [2002] N.B.J. No. 375 (QL), the court held that a risk of transmission of hepatitis C between 1.0 and 2.5% was "so low that it cannot be described as significant" (para. 33). And in *R. v. J.A.T.*, 2010 BCSC 766 (CanLII), the trial judge stated that "[a] significant risk means a risk that is of a magnitude great enough to be considered important" (para. 56).

[91] These considerations lead me to conclude that the *Cuerrier* requirement of "significant risk of serious bodily harm" should be read as requiring disclosure of HIV status if there is a realistic possibility of

transmission of HIV. If there is no realistic possibility of transmission of HIV, failure to disclose that one has HIV will not constitute fraud vitiating consent to sexual relations under s. 265(3)(*c*).

[92] The test of realistic possibility of transmission proposed in these reasons is specific to HIV. As discussed above, "significant risk" depends both on the degree of the harm and risk of transmission. These two factors vary inversely. A treatable sexually transmitted disease that does not seriously alter a person's life or life-expectancy might well not rise to the level of constituting "serious bodily harm", and would also fail to meet the requirement of endangerment of life for aggravated sexual assault under s. 273(1). Where the line should be drawn with respect to diseases other than HIV is not before us. It is enough to note that HIV is indisputably serious and life-endangering. Although it can be controlled by medication, HIV remains an incurable chronic infection that, if untreated, can result in death. As such, the failure to advise a sexual partner of one's HIV status may lead to a conviction for aggravated sexual assault under s. 273(1) of the *Criminal Code*. (This said, it may be that with further medical advances, the death rate may decline to the point where the risk of death is virtually eliminated, reducing the offence to sexual assault *simpliciter* under s. 271(1) of the *Criminal Code*. Similarly, the day may come when researchers will find a cure for HIV, with the possible effect that HIV will cease to cause "serious bodily harm" and the failure to disclose will no longer fall under the category of fraud vitiating consent for the purposes of sexual assault.)

(4) Realistic Possibility of HIV Transmission

[93] A review of the case law pertaining to fraud vitiating consent to sexual relations leads to the following general principle of law: the *Cuerrier* requirement of a "significant risk of serious bodily harm" entails a *realistic possibility of transmission of HIV*. This applies to all cases where fraud vitiating consent to sexual relations is alleged on the basis of the non-disclosure of HIV-positive status.

[94] This leaves the question of when there is a realistic possibility of transmission of HIV. The evidence adduced here satisfies me that, as a general matter, a realistic possibility of transmission of HIV is negated if (i) the accused's viral load at the time of sexual relations was low, *and* (ii) condom protection was used.

[95] The conclusion that low viral count coupled with condom use precludes a realistic possibility of transmission of HIV, and hence does not constitute a "significant risk of serious bodily harm" on the *Cuerrier* test, flows from the evidence in this case. This general proposition does not preclude the common law from adapting to future advances in treatment and to circumstances where risk factors other than those considered in this case are at play.

[96] In this case, the evidence accepted by the trial judge was that Mr. Mabior had intercourse by vaginal penetration with the four complainants, during which he ejaculated. The accused underwent antiretroviral treatment on a regular basis, but he only wore condoms occasionally. Mr. Mabior's medical record also shows that he had been successfully treated for gonorrhœa and had no sexually transmitted infections at the time of intercourse with the four complainants other than HIV. Based on this evidence, three factors were relevant to risk: baseline risk for vaginal intercourse when the male partner is HIV-positive; reduction in risk with condom use; and antiretroviral therapy. I will consider each in turn.

[97] As the Court of Appeal noted, baseline risk of HIV transmission per act of vaginal intercourse with an infected male partner (i.e. the risk of transmission based on the male ejaculating, without a condom, having a normal unreduced viral load) varies from study to study. Dr. Smith's written report put the risk at 0.05% (1 in 2000) to 0.26% (1 in 384) (p. 4). Ms. McDonald, a public health nurse, testified about the Manitoba Health post-exposure protocol, which puts risk per act at 0.1% (1 in 1000). A systemic review and meta-analysis of 43 publications comprising 25 different study populations, put the risk in high-income countries at 0.08% per sexual act (1 in 1250): M.-C. Boily, et al., "Heterosexual risk of HIV-1 infection per sexual act: systematic review and meta-analysis of observational studies" (2009), 9 *Lancet Infect. Dis.* 118.

[98] It is undisputed that HIV does not pass through good quality male or female latex condoms. However, condom use is not fail-safe, due to the possibility of condom failure and human error. Dr. Smith testified that consistent condom protection reduces the risk of HIV transmission by 80%, relying on the widely accepted Cochrane review: S. C. Weller and K. Davis-Beaty, "Condom effectiveness in reducing heterosexual HIV transmission" (2002), 1 *Cochrane Database Syst. Rev*. CD003255. It was pointed out that the 80% reduction in the

transmission risk refers to consistent condom use: the reduction may be larger for consistent *and* correct condom use, but this has not been verified empirically.

[99] The Court of Appeal, in applying a "high risk" approach, held that condom use reduces the risk of HIV transmission "below the level of significance" (para. 87). However, in my view, the evidence does not establish that condom protection alone precludes a *realistic possibility* of transmission, the standard proposed here. According to the expert evidence, the risk might still fall above the "negligible" threshold: Dr. Smith's report, at p. 6.

[100] This brings us to the final factor, antiretroviral therapy. As noted by the Court of Appeal, the transmissibility of HIV is proportional to the viral load, i.e. the quantity of HIV copies in the blood. The viral load of an untreated HIV patient ranges from 10,000 copies to a few million copies per millilitre. When a patient undergoes antiretroviral treatment, the viral load shrinks rapidly to less than 1,500 copies per millilitre (low viral load), and can even be brought down to less than 50 copies per millilitre (undetectable viral load) over a longer period of time. This appears to be scientifically accepted at this point, on the evidence in this case.

[101] Dr. Smith explained in his report that antiretroviral therapy is not a safe-sex strategy, and that "it is highly advisable that persons even with an undetectable viral load who are having sex with more than one partner unfailingly and correctly use a condom" (pp. 5 and 7). The most recent wide-scale study on this issue, relied on by a number of interveners, concludes that the risk of HIV transmission is reduced by 89 to 96% when the HIV-positive partner is treated with antiretrovirals, irrespective of whether the viral load is low or undetectable: M. S. Cohen, et al., "Prevention of HIV-1 Infection with Early Antiretroviral Therapy" (2011), 365 *New Eng. J. Med.* 493. This evidence indicates that antiretroviral therapy, alone, still exposes a sexual partner to a realistic possibility of transmission. However, on the evidence before us, the ultimate percentage risk of transmission resulting from the combined effect of condom use *and* low viral load is clearly extremely low — so low that the risk is reduced to a speculative possibility rather than a realistic possibility.

[102] In reaching this conclusion, I use *low* viral load, rather than *undetectable* viral load, as one of the factors for determining risk. This avoids the evidentiary difficulties associated with establishing an *undetectable* viral load. Dr. Smith presented evidence that various factors such as common infections and treatment issues may lead to fluctuations in a person's viral load. So-called "spikes" or "blips" bring the viral load of a person treated with antiretrovirals above the detectable level. Furthermore, detectability depends on the accuracy of ever-developing technology: a viral load that assays do not detect today, might very well be detectable by future assays. Finally, it must be observed that Dr. Smith did not accept, and presented as controversial, the 2008 announcement by the Swiss Federal Commission for HIV/AIDS that an HIV-positive person with an undetectable viral load is not sexually infectious (p. 5). As he noted, this statement is subject to important qualifications, based only on a review of scientific literature, and requires corroborating research.

[103] This leads to the conclusion that on the evidence before us, the combined effect of condom use *and* low viral load precludes a realistic possibility of transmission of HIV. In these circumstances, the *Cuerrier* requirement of significant risk of serious bodily harm is not met. There is no deprivation within the meaning of *Cuerrier* and failure to disclose HIV status will not constitute fraud vitiating consent under s. 265(3)(*c*) of the *Criminal Code*.

(5) Summary

[104] To summarize, to obtain a conviction under ss. 265(3)(*c*) and 273, the Crown must show that the complainant's consent to sexual intercourse was vitiated by the accused's fraud as to his HIV status. Failure to disclose (*the dishonest act*) amounts to fraud where the complainant would not have consented had he or she known the accused was HIV-positive, and where sexual contact poses a significant risk of or causes actual serious bodily harm (*deprivation*). A significant risk of serious bodily harm is established by a realistic possibility of transmission of HIV. On the evidence before us, a realistic possibility of transmission is negated by evidence that the accused's viral load was low at the time of intercourse and that condom protection was used. However, the general proposition that a low viral load combined with condom use negates a realistic possibility of transmission of HIV does not preclude the common law from adapting to future advances in treatment and to circumstances where risk factors other than those considered in the present case are at play.

[105] The usual rules of evidence and proof apply. The Crown bears the burden of establishing the elements of the offence — a dishonest act and deprivation — beyond a reasonable doubt. Where the Crown has made a *prima facie* case of deception and deprivation as described in these reasons, a tactical burden may fall on the accused to raise a reasonable doubt, by calling evidence that he had a low viral load at the time and that condom protection was used.

B. *Application*

[106] With respect to the four counts before us, the complainants all consented to sexual intercourse with the accused. Each of the complainants testified that they would not have had sex with the accused had they known that he was HIV-positive. The only issue is whether their consent was vitiated because he did not tell them that he had HIV.

[107] The trial judge found the accused guilty of aggravated sexual assault on the four counts where it was established that his viral load was not undetectable or no condom was used. The Court of Appeal set aside the convictions on the basis that *either* an undetectable viral load *or* condom protection would suffice.

[108] As set out above, at this point in the development of the common law, a clear test can be laid down. The absence of a realistic possibility of HIV transmission precludes a finding of fraud vitiating consent under s. 265(3)(*c*) of the *Criminal Code*. In the case at hand, no realistic possibility of transmission was established when the accused had a low viral load and wore a condom. It follows that the appeal should be allowed insofar as the decision of the Court of Appeal conflicts with this conclusion.

[109] The accused had a low viral load at the time of intercourse with each of S.H., D.C.S. and D.H., but did not use a condom. Consequently, the trial judge's convictions on these counts should be maintained. This leaves K.G. The trial judge convicted on the ground that, although the accused used a condom at the time of the encounter, his viral load "was not suppressed" (para. 128). As discussed, the combination of a low viral load — as opposed to an *undetectable* viral load — and of condom use negates a realistic possibility of transmission, on the evidence in this case. The record shows that the accused's viral load was low at the time of sexual relations with K.G. When combined with condom protection, this low viral load did not expose K.G. to a significant risk of serious bodily harm. The trial judge's conviction on this count must be reversed.

[110] I would allow the appeal in part and restore the convictions in respect of the complaints by S.H., D.C.S. and D.H. I would dismiss the appeal in respect of the complaint by K.G.

Appeal allowed in part.

WARNING

The President of the panel hearing this appeal directs that the following should be attached to the file:

An order restricting publication in this proceeding under ss. 486.4(1), (2), (2.1), (2.2), (3) or (4) or 486.6(1) or (2) of the *Criminal Code* shall continue. These sections of *the Criminal Code* provide:

> 486.4(1) Subject to subsection (2), the presiding judge or justice may make an order directing that any information that could identify the victim or a witness shall not be published in any document or broadcast or transmitted in any way, in proceedings in respect of
>
> (a) any of the following offences;
>
> (i) an offence under section 151, 152, 153, 153.1, 155, 159, 160, 162, 163.1, 170, 171, 171.1, 172, 172.1, 172.2, 173, 210, 211, 213, 271, 272, 273, 279.01, 279.011, 279.02, 279.03, 280, 281, 286.1, 286.2, 286.3, 346 or 347, or
>
> (ii) any offence under this Act, as it read at any time before the day on which this subparagraph comes into force, if the conduct alleged involves a violation of the complainant's sexual integrity and that conduct would be an offence referred to in subparagraph (i) if it occurred on or after that day; or
>
> (iii) REPEALED: S.C. 2014, c. 25, s. 22(2), effective December 6, 2014 (Act, s. 49).
>
> (b) two or more offences being dealt with in the same proceeding, at least one of which is an offence referred to in paragraph (a).
>
> (2) In proceedings in respect of the offences referred to in paragraph (1)(a) or (b), the presiding judge or justice shall
>
> (a) at the first reasonable opportunity, inform any witness under the age of eighteen years and the victim of the right to make an application for the order; and
>
> (b) on application made by the victim, the prosecutor or any such witness, make the order.
>
> (2.1) Subject to subsection (2.2), in proceedings in respect of an offence other than an offence referred to in subsection (1), if the victim is under the age of 18 years, the presiding judge or justice may make an order directing that any information that could identify the victim shall not be published in any document or broadcast or transmitted in any way.
>
> (2.2) In proceedings in respect of an offence other than an offence referred to in subsection (1), if the victim is under the age of 18 years, the presiding judge or justice shall
>
> (a) as soon as feasible, inform the victim of their right to make an application for the order; and
>
> (b) on application of the victim or the prosecutor, make the order.

(3) In proceedings in respect of an offence under section 163.1, a judge or justice shall make an order directing that any information that could identify a witness who is under the age of eighteen years, or any person who is the subject of a representation, written material or a recording that constitutes child pornography within the meaning of that section, shall not be published in any document or broadcast or transmitted in any way.

(4) An order made under this section does not apply in respect of the disclosure of information in the course of the administration of justice when it is not the purpose of the disclosure to make the information known in the community. 2005, c. 32, s. 15; 2005, c. 43, s. 8(3)(b); 2010, c. 3, s. 5; 2012, c. 1, s. 29; 2014, c. 25, ss. 22,48; 2015, c. 13, s. 18..

486.6(1) Every person who fails to comply with an order made under subsection 486.4(1), (2) or (3) or 486.5(1) or (2) is guilty of an offence punishable on summary conviction.

(2) For greater certainty, an order referred to in subsection (1) applies to prohibit, in relation to proceedings taken against any person who fails to comply with the order, the publication in any document or the broadcasting or transmission in any way of information that could identify a victim, witness or justice system participant whose identity is protected by the order. 2005, c. 32, s. 15.

COURT OF APPEAL FOR ONTARIO

CITATION: R. v. N.G., 2020 ONCA 494
DATE: 20200805
DOCKET: C66296

Lauwers, Trotter and Fairburn JJ.A.

BETWEEN

Her Majesty the Queen

Respondent

and

N.G.

Appellant

Wayne A. Cunningham, for the appellant

Grace Choi, for the respondent

Richard Elliott and Ryan Peck, for the interveners, the HIV Legal Network, HIV & AIDS Legal Clinic Ontario and Coalition des organismes communautaires québécois de lutte contre le SIDA

Heard: February 12, 2020

On appeal from the conviction entered on November 15, 2017 by Justice Edward E. Gareau of the Superior Court of Justice.

Fairburn J.A.:

OVERVIEW

[1] Over a period of many months, after being diagnosed with HIV and warned about the need to disclose his HIV status to sexual partners, the appellant engaged in repeated acts of vaginal sexual intercourse with three different women. The appellant wore condoms but did not disclose his HIV-positive status and was not on antiretroviral medication. The complainants testified that they would not have

consented to having sexual intercourse with the appellant had they been aware of his HIV-positive status.

[2] The appellant was charged with multiple offences, including three counts of aggravated sexual assault. The trial focused on whether the appellant's failure to disclose his HIV status to the complainants, prior to sexual intercourse, constituted fraud vitiating their consent to that sexual activity in accordance with the principles laid down in *R. v. Mabior*, 2012 SCC 47, [2012] 2 S.C.R. 584. Although one of the complainants was diagnosed with HIV after her sexual relationship with the appellant, there was no proof that she contracted the virus from him.

[3] *Mabior* holds that an accused may be found guilty of aggravated sexual assault under s. 273(1) of the *Criminal Code*, R.S.C. 1985, c. C-46, if he or she fails to disclose an HIV-positive status to a sexual partner, consent to the sexual activity would not have been given had the sexual partner known about that status, and there exists a "realistic possibility of transmission" of HIV during that sexual activity: *Mabior*, at para. 4. The unanimous court in *Mabior* determined that a realistic possibility of HIV transmission is "negated" where two factors come together and work in combination: (a) the non-disclosing person's viral load (the quantity of HIV circulating in his or her blood) at the time of sexual relations is "low"; and (b) a condom is used during the sexual activity in question: *Mabior*, at paras. 94, 103-4.[1]

[4] While the trial judge found as a fact that the appellant used a condom during every act of vaginal sexual intercourse, it is indisputable that the appellant did not have a "low" viral load during a number of those acts of intercourse.

[5] Unable to argue that he met the two-prong test for negating the realistic possibility of transmission of HIV, the appellant instead argued that the *Mabior* test should be changed to reflect the fact that condom use alone is sufficient to negate the realistic possibility of transmission. The trial judge rejected the call to adapt the *Mabior* test and found the appellant guilty on all three counts of aggravated sexual assault.

[6] The appellant then brought a reopening application, at which he sought to introduce expert evidence that use of a condom alone negated any realistic possibility of transmission. The trial judge heard and dismissed the application to reopen the trial. Convictions were entered and the appellant was sentenced to 42 months in custody.

[7] In this court, the appellant renews his argument and seeks to buttress it with fresh evidence. For the reasons that follow, I would dismiss the appeal.

[8] While there is much to be said for the fact that there have been significant medical and scientific strides in our understanding of HIV transmission and treatment in recent years, strides that may well inform the proper direction of the criminal law in the future, I do not accept that the *Mabior* judgment rests on a flawed understanding of the effectiveness of condoms at preventing HIV transmission. The appellant's dispute with *Mabior* rests on the central legal underpinnings of that decision. As I will explain, the reasons for those underpinnings were carefully explained by the unanimous court in *Mabior* and it is not for this court to upend them.

BACKGROUND FACTS

I. The Sexual Activity with A.G.

[9] The appellant and A.G. met on a dating website. She estimated that they had vaginal intercourse 10 to 12 times between September 2013 and October 2014. That activity took place in public parks, behind a school, in the back seats of motor vehicles, and once at A.G.'s home.

[10] A.G. testified that she also performed fellatio on the appellant about 75 or 80 percent of the time that they also had sexual intercourse. He did not use a condom during the fellatio. He sometimes would ejaculate in her mouth and she would swallow his semen.

[11] A.G. testified the appellant always wore a condom during the vaginal intercourse. She recalled bringing the condoms and thought the appellant may have also brought them sometimes. The appellant would put condoms on himself after he had an erection. A.G. could not recall a condom breaking.

[12] When A.G. found out about the appellant's HIV-positive status, she "died a little bit inside." She felt suicidal while awaiting test results to determine whether she had contracted the disease. She ultimately tested negative. She testified that she would not have consented to any sexual activity with the appellant had she known his HIV-positive status.

II. The Sexual Activity with A.C.

[13] The appellant also met A.C. through a dating website. Their sexual relationship involved mutual oral sex without condoms. It also involved vaginal sexual intercourse. That activity took place between July 2013 and March 2014. Although much of their sexual activity took place at A.C.'s home, the appellant and A.C. also had intercourse outside in the bushes and on the ground. During certain periods of time, they had intercourse a couple of times a week.

[14] A.C. said that the appellant would bring his own condoms and put them on. She said that she could hear the package open and saw them "being disposed [of] because most times I would give him the Kleenex, he'd put it in the Kleenex, and I would throw it away". Like A.G., she would not have consented to engaging in sexual activity with the appellant had she known his HIV status. This was particularly true given that she had her own serious health issues at the time.

[15] Although A.C. tested positive for HIV in October 2014, there was no finding that she contracted the disease from the appellant.

III. The Sexual Activity with N.W.

[16] The appellant's brother introduced N.W. to the appellant. N.W. testified about numerous incidents of oral sex and at least one incident of vaginal intercourse that took place at her home somewhere between December 2013 and January 2014. The trial judge found that a condom was used during sexual intercourse.

[17] Like the other complainants, N.W. testified that she would not have consented to engaging in any sexual activity with the appellant had he disclosed his HIV-positive status to her.

IV. The Uncontroverted Facts About the Appellant's Viral Load

[18] Health authorities informed the appellant about his HIV-positive status on October 20, 2013. At that point, his sexual relationships with A.G. and A.C. had already started. The appellant was told about the risks of transmission, the importance of using condoms, and the need to disclose his HIV-positive status to all sexual partners.

[19] The appellant did not start taking antiretroviral medication until April 3, 2014, over five months after diagnosis. Despite having been specifically warned about the risk of transmission and need for disclosure, the appellant continued in his sexual relationships with A.C. and A.G., and started his sexual relationship with N.W., without disclosing to any of them.

[20] Between his initial diagnosis and his first viral load reading after beginning antiretroviral drugs, the appellant's viral load ranged between 11,345 and 27,868 copies of HIV in a millilitre of blood, well above the 1,500 copies described as "low" in *Mabior*. The higher the number, the greater the risk of transmission: *Mabior*, at para. 100. By October 29, 2014, the appellant's viral load had become non-detectable.

[21] Therefore, there is no dispute in this case that the appellant was having vaginal sexual intercourse with the complainants during a time when his viral load was not low within the meaning of *Mabior*.[2] Accordingly, despite his use of condoms, the appellant failed to meet the *Mabior* test for negating a realistic possibility of transmission of HIV during those sexual acts.

V. Defence Expert at Trial: Dr. Wendy Wobeser

[22] The defence called an infectious disease specialist, Dr. Wendy Wobeser. She was qualified to give opinion evidence in the following areas: (a) biology and treatment of HIV; (b) the risk of transmission of HIV; and (c) the general area of infectious diseases.

[23] Dr. Wobeser testified that HIV is a necessary precursor to Acquired Immune Deficiency Syndrome ("AIDS"). Given the advances in science and the availability of antiretroviral medication, today, very few people with HIV develop AIDS. Even so, Dr. Wobeser testified that HIV remains a serious, life-endangering infection if not treated properly.

[24] The most significant risk factors for a person with HIV transmitting the infection through sexual activity are: (a) whether a condom is used; (b) the person's viral load; (c) whether the person is undergoing antiretroviral therapy; and (d) the type of sexual activity undertaken. She testified that vaginal-penile intercourse is less likely to result in transmission of the virus than anal intercourse, with anal intercourse being the highest risk sexual activity for transmission.

[25] Where condoms are used, and "everything works", Dr. Wobeser testified that the risk of HIV transmission is zero. She referred to a study that was cited in *Mabior* with reference to the effectiveness of condoms at preventing transmission: Susan C. Weller and Karen Davis-Beaty, "Condom Effectiveness in Reducing Heterosexual HIV Transmission" (2002), 1 Cochrane Database Syst. Rev. CD003255

["Cochrane Review"]. Relying upon the Cochrane Review, she referred to the fact that, in the "real world", condom use reduces the baseline risk (the actual rate at which something occurs in a given population) of HIV transmission by 80 to 85 percent.

PROCEEDINGS BELOW

I. Reasons for Judgment at Trial

[26] Relying upon Dr. Wobeser's evidence, the trial judge accepted as a fact that, where condoms work, the risk of transmission of HIV is "zero". Even so, he concluded that condoms only provide 80 to 85 percent effectiveness in the "real world", and probably closer to the 80 percent range. As the trial judge said:

> The act of sexual intercourse is not a theoretical concept where theoretical statistics and theories should be applied. It is, rather, a real life action where real life scenarios and real life numbers should be applied. In theory, if all is perfect it may very well be that condom use is 100% effective in [preventing the transmission of] the HIV virus, but the sexual act between two people is not a theoretical experience; it is a real life action where realistic approaches should be taken especially when it concerns the realistic possibility of the transmission of the HIV virus, which is still a life threatening virus if left untreated.

[27] The trial judge rejected as unpersuasive the reasoning in another trial decision where an accused was acquitted of aggravated sexual assault on the basis of condom use alone: see *R. v. Thompson*, 2016 NSSC 134, 373 N.S.R (2d) 167, rev'd but not on this point 2018 NSCA 13, 359 C.C.C. (3d) 222.[3] He also felt bound by this court's decisions in *R. v. Felix,* 2013 ONCA 415, 307 O.A.C. 248 and *R. v. Mekonnen,* 2013 ONCA 414, 299 C.C.C. (3d) 134, two cases that applied the *Mabior* rule for negating the realistic possibility of HIV transmission.

[28] While the trial judge accepted that a great deal has changed in relation to antiretroviral therapy, a subject I will return to later, he concluded that "when the scientific evidence as a whole is examined with respect to condom use in real life situations", nothing had changed since *Mabior*. Therefore, he found:

> Since there is not the combined effect of a low viral load and condom use at the time [the appellant] had sexual intercourse with A.C., A.G., and N.W., there exists, in law, a realistic possibility of HIV transmission during the occurrences of sexual intercourse that [the appellant] had with A.C., A.G., and N.W. [Emphasis in original.]

[29] The appellant was found guilty of three counts of aggravated sexual assault.

II. The Reopening Application

[30] After being found guilty of three counts of aggravated sexual assault, the appellant brought an application to reopen the trial. In support of that application, the appellant filed the affidavit of Dr. John Richard Middleton Smith, the same expert who testified in *Mabior.* Like Dr. Wobeser at trial in this case, during his evidence in *Mabior,* Dr. Smith relied upon the Cochrane Report to estimate the reduction in the baseline risk of HIV transmission when condoms are used. As the court noted in *Mabior,* at para. 98: "Dr. Smith testified that consistent condom protection reduces the risk of HIV transmission by 80%, relying on the widely accepted Cochrane review."

[31] On the reopening application at trial, Dr. Smith said that his thinking on the risks associated with the sexual transmission of HIV where condoms are used has evolved since he testified in *Mabior*. Adopting a passage from a consensus statement prepared by Canadian experts in the field of HIV, Dr. Smith now emphasizes that "when correctly used and no breakage occurs, condoms are 100% effective at stopping the transmission of HIV" (emphasis added): see *Loufty*, *et al.*, "Canadian Consensus Statement on HIV and its Transmission in the Context of Criminal Law" (2014), 25:3 Can J. Infect Dis. Med. Bicrobiol. 135 ["Canadian Consensus Statement"].

[32] Dr. Smith now underscores that the 80 to 85 percent effectiveness rate for condoms, as reflected in the Cochrane Review, is only applicable at a population level and, in his view, should no longer be used for assessing individual risk on a per sex act basis. As he said:

> It is simply incorrect to state that in [an] individual case condoms are only 80-85% effective. In my opinion an individual who always uses a condom and is careful in its use can be almost 100% sure that the HIV virus will not be transmitted.

…

> In my opinion, it is agreed amongst the medical profession, that as far as science has been able to determine, condoms are near 100% effective in preventing HIV transmission if correctly used. I say near 100% because of the negligible prospect that even when properly used, there may be an unknown problem with the condom that allows transmission of bodily fluid. [Emphasis added.]

[33] In the trial judge's view, Dr. Smith's evidence added nothing new to the evidence of Dr. Wobeser that, where condoms work perfectly, the HIV transmission rate is zero. The trial judge concluded, though, that the condom error rate across the population is still an important consideration when determining the realistic possibility of transmission of HIV because sexual intercourse takes place in the "real world" where condoms do not always perform perfectly. Accordingly, he concluded that Dr. Smith's evidence was insufficiently cogent to be granted admission on the reopening application. The application was dismissed, and the matter proceeded to sentencing.

ANALYSIS

I. Overview

[34] In challenging his convictions, the appellant returns to the same argument he made at trial and on the reopening application. He contends that the *Mabior* requirement that condom use be coupled with a low viral load in order to negate a realistic possibility of transmission of HIV overshoots the mark. He says that condom use alone should be sufficient to negate the realistic possibility of transmission because "consistent and correct" condom use creates a zero percent chance of transmission.

[35] Although the appellant acknowledges that in rare situations condoms will fail, he says that this failure is strictly owing to incorrect usage. Therefore, according to the appellant, where a condom is used, regardless of the level of the HIV-positive sexual partner's viral load, condom usage alone should be sufficient to negate the realistic possibility of HIV transmission. To displace that presumption, the appellant contends that it should fall to the Crown to prove condom failure.

[36] At the same time, and importantly, the appellant is not prepared to acknowledge that the criminal law necessarily has a role to play in the wake of condom failure. He argues that all issues surrounding the mechanics of such proof, and whether proof of condom failure could even rise to the level of criminality, be left to another day. Therefore, I refer to the appellant's position on this appeal as a condom-alone rule.

[37] Although they put it slightly differently, the interveners join the appellant in the position that "correct" condom use alone should be able to negate the *Mabior* threshold of a realistic possibility of transmission. They ask this court to "conclude as a matter of law", that:

> (i) condom use *per se* can negate a realistic possibility of transmission for the purpose of the criminal law, and
>
> (ii) there is no realistic possibility of transmission in the case of correct condom use (i.e., "the integrity of the condom is not compromised and the condom is worn throughout the sex act in question"). [Emphasis in original. Footnote omitted.]

[38] To be clear, this case is not about advances in the understanding around the non-transmissibility of HIV in the context of a suppressed or undetectable viral load. In particular, it does not raise the question of whether a suppressed or undetectable viral load, standing on its own, should now be sufficient to negate the realistic possibility of transmission.

[39] The sole issue that this court is asked to resolve in this case is whether, at law, the use of a condom alone – despite the presence of a non-low or perhaps even high viral load – should remove HIV non-disclosure cases from the reach of the criminal law, barring proof that the condom failed in some way. The record before this court addressed that issue alone, and the legal argument followed suit.

[40] The appellant makes two broad arguments in support of his position that it is open to this court to set aside the *Mabior* finding that condom use alone does not negate the realistic possibility of HIV transmission. He maintains that this court can arrive at a different conclusion than *Mabior* on this point because, in determining the rate at which condoms fail to protect against the baseline risk of HIV transmission, the Supreme Court of Canada (a) relied upon Dr. Smith's approach to population-level statistics, an approach that Dr. Smith no longer endorses; and (b) relied upon what are in hindsight flawed statistics.

[41] In support of his argument, the appellant relies upon the evidence of Dr. Smith at the reopening application, as well as evidence contained within a fresh evidence record on appeal. Together, I will refer to all of this evidence as the "new evidence".

[42] The appellant acknowledges that if he is unsuccessful in having his fresh evidence admitted on appeal, then it is unrealistic to expect that this court will find error with the trial judge's decision to exclude Dr. Smith's evidence on the reopening application. His position on this point is a sensible one, particularly given that the tests for the admission of evidence on a reopening application and on appeal align.

[43] In a judge alone trial, a finding of guilt can be vacated prior to the sentence being imposed or other final disposition made, but this should only occur in "exceptional circumstances and where it is clearly called for": *R. v. Lessard* (1976), 1976 CanLII 1417 (ON CA), 30 C.C.C. (2d) 70 (Ont. C.A.), at p. 73. Where an application to reopen a trial is predicated on the admission of further evidence, the well-known *Palmer* test for the admission of fresh evidence on appeal applies: *R. v. Palmer*, 1979 CanLII 8 (SCC), [1980] 1 S.C.R. 759, at p. 775; *R. v. Kippax*, 2011 ONCA 766, 286 O.A.C. 144, at para. 63, leave to appeal refused, [2012] S.C.C.A. No. 92. The *Palmer* criteria are now commonly understood as reflected in a three-part test:

> Is the evidence admissible under the operative rules of evidence?
>
> Is the evidence sufficiently cogent in that it could reasonably be expected to have affected the result?
>
> What is the explanation offered for the failure to adduce the evidence at trial and should the explanation affect the admissibility of the evidence on appeal?

Truscott (Re), 2007 ONCA 575, 226 O.A.C. 200, at para. 92; *R. v. Reeve,* 2008 ONCA 340, 236 O.A.C. 92, at para. 66.

[44] The central question in this appeal is whether the trial judge erred when he concluded that Dr. Smith's evidence was insufficiently cogent to be granted admission on the reopening application.[4] There are three aspects to the cogency consideration:

> Is the evidence relevant in that it bears upon a decisive or potentially decisive issue at trial?
>
> Is the evidence credible in that it is reasonably capable of belief?
>
> Is the evidence sufficiently probative that it could reasonably, when taken with the other evidence adduced at trial, be expected to have affected the result?

Truscott, at para. 99.

[45] The first two cogency requirements are clearly met in this case.

[46] First, the new evidence bears upon a decisive issue at trial, being whether the appellant's use of condoms negated the realistic possibility of transmission of HIV despite his viral load.

[47] Second, there is no dispute that the new evidence is credible. No one suggests otherwise.

[48] The real question is whether, when considered against all of the evidence at trial, the new evidence is "sufficiently probative" to allow this court to change the *Mabior* rule, so that condom use alone can negate the realistic possibility of HIV transmission, thereby requiring acquittals to be entered. I see no error in the trial judge's conclusion that Dr. Smith's evidence was insufficiently cogent to be granted admission on the reopening application. There is nothing in the fresh evidence on appeal that changes my view in that regard.

II. The *Mabior* Rule for Fraud Vitiating Consent

[49] In order to understand the appellant's position about why condom use alone should negate the realistic possibility of transmission, it is first necessary to understand how the Supreme Court of Canada came to reject that very suggestion in *Mabior.* I will start by reviewing the *Mabior* test and how it came to be. I will then address the narrow basis upon which that test can be revisited by lower courts, after which I will explain why, in my view, the appellant's arguments for adapting the test must fail.

1. From *Cuerrier* to *Mabior*

[50] A range of criminal offences have been used to prosecute HIV non-disclosure cases in Canada, such as criminal negligence causing bodily harm, common nuisance, administering a noxious substance, attempted murder, murder, and various degrees of assault and sexual assault.[5] A report prepared by the Department of Justice suggests that aggravated sexual assault is the most frequently prosecuted offence in this context: Canada, Department of Justice, *Criminal Justice System's Response to Non-Disclosure of HIV* (2017), at p. 15 ["Department of Justice Report"].

[51] This case, *Mabior*, and *Mabior's* predecessor, *R. v. Cuerrier,* 1998 CanLII 796 (SCC), [1998] 2 S.C.R. 371, are all cases involving convictions for aggravated sexual assault. The reasons must be considered within that offence-based context. Therefore, to understand the *Mabior* rule that lies at the centre of this appeal, it is necessary to first understand how consent operates in the context of sexual assault prosecutions involving HIV non-disclosure.

[52] Consent to sexual activity constitutes the voluntary agreement to "engage in the sexual activity in question": *Criminal Code*, s. 273.1(1). Consent must be freely given, constituting the "conscious agreement of the complainant to engage in every sexual act in a particular encounter": *R. v. J.A.*, 2011 SCC 28, [2011] 2 S.C.R. 440, at para. 31.

[53] Consent as defined in s. 273.1(1) of the *Criminal Code* is not to be "considered in the abstract": *R. v. Barton,* 2019 SCC 33, at para. 88. Rather, as set out in *R. v. Hutchinson,* 2014 SCC 19, [2014] 1 S.C.R. 346, at paras. 55, 57, and recently reinforced in *Barton,* at para. 88, consent is linked to the "sexual activity in question", which encompasses "the specific physical sex act", "the sexual nature of the activity", and the "identity of the partner". It does not, though, include the "conditions or qualities of the physical act, such as … the presence of sexually transmitted diseases". See also: *R. v. Kirkpatrick,* 2020 BCCA 136, at para. 89, *per* Bennett J.A. (majority).

[54] Even where the requirements of s. 273.1(1) are met – the complainant has agreed to the specific physical sex act, the sexual nature of the act, and the identity of the sexual partner – this does not end the inquiry into whether consent has been given. This is where ss. 265(3) and 273.1(2) of the *Criminal Code* come into play, setting out the circumstances where consent is deemed not to have been given: *R. v. Ewanchuk*, 1999 CanLII 711 (SCC), [1999] 1 S.C.R. 330, at para. 36.

[55] As first addressed in *Cuerrier*, HIV non-disclosure cases prosecuted as aggravated sexual assault engage directly with s. 265(3)(c) of the *Criminal Code*, dealing with fraud capable of vitiating consent:

> For the purposes of this section, no consent is obtained where the complainant submits or does not resist by reason of
>
> …
>
> (c) fraud.

[56] Seven judges sat in *Cuerrier* and three judgments emerged. Cory J. held the plurality. His decision set the course for how the fraud component in s. 265(3)(c) operates to vitiate consent where certain criteria are present in HIV non-disclosure cases. Like *Mabior* and this case, *Cuerrier* also involved HIV non-disclosure in the context of acts of vaginal-penile sexual intercourse.

[57] Expressing concern over casting the criminal net too widely, Cory J. determined that HIV non-disclosure could only constitute fraud capable of vitiating consent if two things were proven: (a) a deception; and (b) a deprivation or risk of deprivation.

[58] The deception component of s. 265(3)(c) can be proven through either an active lie about one's HIV status, or silence as to that status: *Cuerrier*, at para. 126.

[59] The deprivation component can be proven through actual harm (the actual transmission of the virus) or through a "risk of deprivation" (a risk of transmission of the virus). A "risk of deprivation" means that the complainant did not contract HIV through the sexual activity in question but was placed at risk of contracting the disease during that activity. It is the "risk of deprivation" component of the element of fraud under s. 265(3)(c) that has attracted substantial attention in the context of HIV non-disclosure cases.

[60] Where the prosecution is relying upon only a risk of deprivation to vitiate consent (as in *Cuerrier, Mabior*, and this case), according to *Cuerrier,* the risk must rise to the level of a "significant risk of serious bodily harm": at paras. 128, 135. See also: *Hutchinson*, at para. 34.

[61] In time, that test proved somewhat elusive and difficult to apply, resulting in concerns regarding the inconsistent application of the test and the overbroad application of the criminal law: *Mabior*, at paras.

13-15. These concerns eventually resulted in two different appellate courts specifically asking the Supreme Court of Canada for clarification on the test: *R. v. Mabior*, 2010 MBCA 93, 245 Man. R. (2d) 81, at para. 152; *R. v. D.C.*, 2010 QCCA 2289, 270 C.C.C. (3d) 50, at para. 121.

[62] The Supreme Court answered that call in *Mabior*.[6]

[63] The parties and interveners in *Mabior* advanced various models for solving the perceived difficulties arising from the *Cuerrier* test. Each model was rejected by the court, including the suggestion by Mr. Mabior that judicial notice be taken of the fact that "condom use always negates a significant risk of serious bodily harm": *Mabior,* at para. 70.

[64] Ultimately, the Supreme Court refused to jettison the *Cuerrier* test. Instead, the court opted to clarify the meaning of that test for purposes of finding a sufficient risk of deprivation to vitiate consent in the context of HIV non-disclosure. The court concluded that a significant risk of serious bodily harm is established where there exists a "realistic possibility of transmission of HIV": *Mabior,* at paras. 4, 84, 91, 93, 104, 108. In other words, where a person fails to disclose his or her HIV-positive status before engaging in sexual intercourse, in circumstances where there exists a realistic possibility of HIV transmission, a deception and risk of deprivation will align such that fraud will be capable of vitiating the unwitting sexual partner's consent.

[65] In an effort to provide even further clarity in the law, the *Mabior* court went on to explain, at para. 94, that where two factors come together to form a symbiotic relationship, the realistic possibility of HIV transmission will be negated:

> This leaves the question of when there is a realistic possibility of transmission of HIV. The evidence adduced here satisfies me that, as a general matter, a realistic possibility of transmission of HIV is negated if (i) the accused's viral load at the time of sexual relations was low *and* (ii) condom protection was used [Italics in original, underline added.]

[66] In other words, *Mabior* made clear that if a person's viral load is "low" during sexual relations and a condom is used during those relations, the realistic possibility of HIV transmission will be negated. Therefore, as a matter of criminal law, *Mabior* clarified that where these two things align, there will be no realistic possibility of HIV transmission, thereby removing the risk of deprivation necessary for consent to be vitiated under s. 265(3)(c) of the *Criminal Code*.

[67] While the *Mabior* decision places the burden on the Crown to establish the dishonest act and risk of deprivation beyond a reasonable doubt, the court made the practical observation, at para. 105, that where the Crown establishes a *prima facie* case of deception and deprivation, a tactical burden may shift to the accused to trigger the two-part test:

> The usual rules of evidence and proof apply. The Crown bears the burden of establishing the elements of the offence – a dishonest act and deprivation – beyond a reasonable doubt. Where the Crown has made a *prima facie* case of deception and deprivation as described in these reasons, a tactical burden may fall on the accused to raise a reasonable doubt, by calling evidence that he had a low viral load at the time and that condom protection was used. [Emphasis added.]

[68] The application of the test to the facts of *Mabior* assists in understanding how it is intended to operate. The court allowed the appeal insofar as the decision of the Court of Appeal had conflicted with the test. This led to the reinstatement of convictions where, despite Mr. Mabior's low viral load, he did not use a condom during vaginal sexual intercourse: *Mabior*, at paras. 108-9. See also this court's application of this test for negating a realistic possibility of HIV transmission in *Felix*.

[69] Having completed this review of the *Mabior* rule that is under challenge in this appeal, and before moving on, it is perhaps worth emphasizing the crux of HIV non-disclosure cases prosecuted as aggravated sexual assaults. The essence of the crime lies in the failure to disclose one's HIV-positive status to an unwitting sexual partner in circumstances where there exists a realistic possibility of transmission of the virus to that unwitting partner. In my view, what is criminalized is the unilateral imposition of risk of very serious harm onto another person without offering the at-risk party an opportunity to decide whether to assume that risk, or how to manage that risk, before making a decision to proceed.

2. The Importance of *Stare Decisis*

[70] The principle of *stare decisis* casts a long shadow in this case and, as I will explain, governs the result.

[71] There are sound reasons for why, except in limited circumstances, lower courts do not depart from precedents of higher courts. At the forefront of those reasons is the need for certainty in the law. As noted in *Canada (Attorney General) v. Bedford*, 2013 SCC 72, [2013] 3 S.C.R. 1101, at para. 38:

> Certainty in the law requires that courts follow and apply authoritative precedents. Indeed, this is the foundational principle upon which the common law relies.

[72] Despite the importance of certainty in the law, and the need to follow precedent in order to achieve that certainty, where the factual underpinnings guiding a legal decision give way, so too may the principle of *stare decisis.* Indeed, the *Mabior* decision makes specific note of this fact.

[73] *Mabior* is clear that the means by which a realistic possibility of HIV transmission can be negated – condom use combined with a low viral load – represents a conclusion that is inextricably linked to the factual record before the court: see, for instance, paras. 94, 95, 101, 103, 109. The decision is also clear that the court was alive to the fact that this approach to negating risk is directly linked to science and medicine, both disciplines that are inherently dynamic in nature and ever on the move toward better health outcomes.

[74] Recognizing that medical and scientific developments may take place in the future, the court extended – twice over – a specific invitation to lower courts to, if necessary, adapt the means by which a realistic possibility of HIV transmission can be negated:

> The general proposition that a low viral load combined with condom use negates a realistic possibility of transmission of HIV does not preclude the common law from adapting to future advances in treatment and to circumstances where risk factors other than those considered in the present case are at play. [Emphasis added.]

Mabior, at para. 104. See also para. 95.

[75] The appellant argues that the *Mabior* invitation to adapt is this court's gateway to reconsidering the factors that must be at play before a realistic possibility of transmission can be negated. I do not agree.

[76] While I accept that the *Mabior* decision leaves it open to lower courts to adapt the criteria necessary to negate a realistic possibility of HIV transmission, it does so in a way that is consistent with the principles of *stare decisis.* In my view, the invitation to adapt is directly linked to "future advances in treatment and to circumstances where risk factors other than those considered" in *Mabior* are at play. In other words, the invitation to adapt is linked to potential changes to the factual pillars upon which *Mabior* rests, in circumstances where those pillars are particularly susceptible to change.

[77] As I will shortly explain, though, the appellant's argument in favour of a condom alone rule rests on a challenge, not to the factual pillars upon which *Mabior* rests, but to the legal foundation upon which the decision rests.

[78] Although I take no final view on the matter, because it extends beyond the scope of this judgment, it is noteworthy that since *Mabior* was decided, it is arguable that the factual underpinnings of the decision have already changed, although not in relation to the effectiveness of condoms. There appears to have been significant changes involving the understanding around the ability to transmit HIV with a suppressed or undetectable viral load. The record in this case includes references to the post-*Mabior* medical and scientific communities' broad consensus that it is no longer considered possible to transmit HIV with a suppressed or undetectable viral load: see *Barre-Sinoussi et al.*, "Expert Consensus Statement on the Science of HIV in the Context of Criminal Law" (2018), 21:7 J. Int'l AIDS Society e25161, at s. 2.1 ["International Consensus Statement"]; Canadian Consensus Statement, at pp. 136-7.

[79] So widely accepted is that view today that it appears some prosecution services across the country have now put policies in place directing Crown counsel not to prosecute HIV non-disclosure cases any longer in circumstances where the HIV-positive partner's viral load is either suppressed (a level defined within those policies) or undetectable: see e.g., Federal: Office of the Director of Public Prosecution, *Directive* (30 November 2018) [Federal Prosecution Policy]; Ontario: Ministry of the Attorney General, "D. 33 Sexual Offences Against Adults: Sexually Transmitted Infections and HIV Exposure Cases", in *Crown Prosecution Manual* (December 1, 2017); British Columbia: Prosecution Service, "Sexual Transmission, or Realistic Possibility of Transmission, of HIV, in *Crown Counsel Policy Manual* (April 16, 2019).

[80] Lower courts have also started acknowledging that viral loads below a defined level, standing on their own, are sufficient to negate the realistic possibility of HIV transmission: see e.g., *R. v. Vatcher* (November 22, 2019), Ottawa, 0411-998-17-51-27 (Ont. C.J.); *R. v. J.T.C.*, 2013 NSPC 105, at paras. 55-

56, 63, 99-101; *R. v. J.T.C.*, 2013 NSPC 88, at paras. 14-15, 17, 19-21; *R. v. C.B.*, 2017 ONCJ 545, at paras. 87, 90-92, 99; *Thompson*, at paras. 97, 132-134.

[81] Without weighing in on the matter, as it is not before us, the apparent evolution in the medical and scientific communities' understandings around the transmissibility of HIV in the face of suppressed or undetectable viral loads illustrates precisely the kind of evolution the *Mabior* court left open for consideration in the future. This is the kind of situation where *stare decisis* would not bind lower courts to the *Mabior* rule.

[82] In my view, the new evidence in this case is not of a similar type. Its primary focus is not upon changes to the factual backdrop upon which the *Mabior* decision rests. Rather, its primary focus is upon desired changes to the legal foundations upon which the *Mabior* decision rests.

III. The New Evidence Does Not Add Anything New

1. The New Evidence

[83] At the reopening application, Dr. Smith expressed that he has changed his mind since *Mabior* about the appropriateness of using population-level statistics when considering the risk of HIV transmission in the context of the criminal law. He reinforced this view in his fresh evidence on appeal.

[84] As reflected in the *Mabior* decision, Dr. Smith provided evidence that the baseline risk of HIV transmission per act of unprotected vaginal-penile sexual intercourse (no condom and a non-low viral load), where the male partner is HIV-positive, varies from "study to study", but is somewhere between 1 in 2,000 and 1 in 384. The court also summarized other evidence, suggesting that the baseline risk of transmission in these circumstances ranges from 1 in 1,000 to 1 in 1,250: *Mabior*, at para. 97. In this case, Dr. Wobeser referred to this baseline risk of transmission as around 8 in 10,000.

[85] The Supreme Court relied upon the Cochrane Review, as put forward by Dr. Smith in *Mabior*, for the proposition that "consistent" condom use can reduce that baseline risk by 80 percent: *Mabior*, at para. 98. The court concluded that, despite the reduction in risk of transmission provided by condom use, something more was required to negate the "realistic possibility of transmission": *Mabior*, at para. 99. That something more is a low viral load.

[86] Contrary to his *Mabior* evidence, Dr. Smith now eschews the use of the Cochrane Report – predicated on population-level statistics – to determine the effectiveness of condoms at reducing the risk of HIV transmission. Dr. Smith now opines that: "it is incorrect to state that in any individual case condoms are only 80% to 85% effective" because, in his current view, correct and consistent condom use leads to 100 percent protection from transmission when considered on a per act basis where nothing goes wrong.

[87] While Dr. Smith acknowledges that condoms do fail from time-to-time, it is his view that the law should only consider what happened in each individual case. As he puts it: "[o]ne has to find out the truth of what occurred" and the "legal system should not be dealing with cases where there [has] not been transmission". He says that, instead, the legal system should only "function" by looking at the "outcome of the event", rather than the risk going into the event.

[88] In formulating his opinion, Dr. Smith relies upon a number of reports, including the Canadian Consensus Statement, where HIV physicians and medical researchers have expressed a similar view. That report is aimed at addressing what the authors perceive to "be at stake in individual criminal cases" and "does not extend to HIV transmission at a population level in relation to HIV prevention efforts" (emphasis added): at p. 136.

[89] Within that context, the authors focus upon condoms that are "used correctly" and where "no breakage occurs." The authors specifically point out that their opinion is based upon the assumption that the "condom was applied to the penis and worn throughout sex, and that no condom breakage occurred": at p. 136.[7] Assuming these prerequisites are met, the Canadian Consensus Statement says "condoms are 100% effective at stopping the transmission of HIV": at p. 136.

[90] Dr. Smith also relies upon the International Consensus Statement to a similar end. That report was prepared by 20 HIV scientists from different regions across the world. "Correct" condom use is defined as a condom being worn throughout the sex act and its integrity not being compromised: International Consensus Statement, at s. 2.2.

[91] Bearing that definition in mind, the International Consensus Statement concludes that when a condom is correctly used, in an individual act of sexual intercourse, there is zero risk of transmission of HIV because bodily fluids containing the virus, like blood, semen, pre-seminal fluid, vaginal and anal fluids, cannot come into direct contact with sites in the body of an HIV-negative person where infection

can be initiated, like mucous membranes or damaged tissue: International Consensus Report, at ss. 2.1 and 2.2.

[92] Finally, Dr. Smith relies upon the Department of Justice Report, that concludes with a recommendation that the criminal law should "generally not apply to persons living with HIV who … are not on treatment but use condoms … because the realistic possibility of transmission test is likely not met" (emphasis added): at p. 30. The appellant points out that in response to that report, the Attorney General of Canada adapted its policy direction to federal prosecutors, suggesting that the Director "shall generally not prosecute…where the person has not maintained a supressed viral load but used condoms or engaged only in oral sex or was taking treatment as prescribed, unless other risk factors are present" (emphasis added): see Federal Prosecution Policy.

[93] The Crown responds with evidence from two other experts: (a) Dr. William Yarber, a health behavioural scientist with specialized knowledge in the area of male condoms and problems with usage; and (b) Dr. David Fisman, the current Head of the Division of Epidemiology at the University of Toronto, with an expertise in, among other things, the epidemiology of sexually transmitted diseases including HIV. As will be explained later, Dr. Yarber catalogues the multiple challenges associated with "correct" condom use and the difficulties in achieving a perfect latex barrier to transmission. Among other things, Dr. Fisman addresses the importance of using population-level statistics when determining the risk of transmission associated with a sexual activity before it is undertaken.

2. There is No Basis to Revisit the Supreme Court's Reliance on Population-Level Statistics

[94] The appellant points to the following sentence from *Mabior*, at para. 98, to suggest that the court did not understand what he argues the new evidence shows, that consistent and correct condom use makes for a zero risk of transmission:

> Dr. Smith testified that consistent condom protection reduces the risk of HIV transmission by 80%, relying on the widely accepted Cochrane review …. It was pointed out that the 80% reduction in the transmission refers to consistent condom use: the reduction may be larger for consistent *and* correct condom use, but this has not been verified empirically. [Emphasis added.]

[95] The appellant and interveners argue that the new evidence now verifies empirically that consistent and correct condom use brings the risk of HIV transmission to zero and *Mabior* should be adapted accordingly. Although they accept that some people are irresponsible condom users, they argue that the lack of due care on the part of others should not be visited upon responsible condom users. In other words, the criminal law should not be used to punish those who correctly use their condoms because those individuals do not place their sexual partners at risk.

[96] The interveners clearly and helpfully summarize this position in the following passage reproduced from their factum:

> By definition, population-level estimates factor in instances where condoms are not used correctly; those instances reduce the overall observed effectiveness, at the population level, of condoms for HIV prevention. It is unfair to convict an individual condom user – whose correct use of a condom would mean zero risk of transmission – on the basis of a population-level estimate that condoms are "only" 80% effective in reducing the risk of transmission (already an exceedingly small per-act risk), particularly in the absence of a finding that that individual engaged in incorrect condom use. [Emphasis added.]

[97] In my view, there are three overarching difficulties with the appellant and interveners' position: (a) the position conflates "consistent and correct" condom use with the ideal scenario in which condoms function perfectly, thereby failing to account for real-world situations in which condoms do not function perfectly; (b) it is contrary to the principles underlying epidemiology and the criminal law; and (c) it is inconsistent with the *Charter* values animating the *Mabior* rule.

a. "Consistent and Correct" Condom Use Does Not Mean Zero Risk of Transmission

[98] First, the position conflates fundamentally different concepts. The term "correct condom use" is used as if it were a proxy for knowing in advance that a condom would be used perfectly and that the condom would function perfectly. These are not the same things.

[99] There is no dispute that a perfectly functioning latex condom provides a perfect barrier to HIV transmission. Indeed, the Supreme Court of Canada well appreciated this fact in *Mabior*, as reflected at

para. 98 of the decision: “It is undisputed that HIV does not pass through good quality male or female latex condoms”.

[100] But, as the Supreme Court of Canada also understood, condoms do not always work as they are intended to work: “condom use is not fail-safe, due to the possibility of condom error and human error”: *Mabior,* at para. 98. Indeed, from time-to-time, despite the very best intentions and efforts of sexual partners, condoms sometimes fail to work. Dr. Smith agreed during cross-examination that it is “not possible to know prior to a sexual encounter whether perfect or correct use versus condom failure may happen.”

[101] Indeed, this court recently captured this concept in *R. v. Boone,* 2019 ONCA 652, at para. 122:

> Dr. Tyndall agreed with Dr. Remis that condom use reduced the risk of transmission overall by about 80 percent. Dr. Tyndall also testified that if the condom was properly applied and did not malfunction during use, the risk reduction approached very near 100 percent. Of course, no one could know ahead of any particular sexual activity whether the condom would malfunction in some way.

[102] There is an ample record on appeal, primarily led through Dr. Yarber’s affidavit evidence, testimony, and accompanying reports, that supports the fact that sometimes condoms slip, break, leak, and otherwise fail. These events can happen despite efforts to the contrary.

[103] As the respondent points out, multiple experts in this case, including Dr. Wobeser, Dr. Smith, and Dr. Yarber, provided evidence demonstrating just how many things can go wrong with male latex condoms, including:

- Using a condom that has expired
- Using a condom that has been incorrectly stored, including in a pocket and sat on
- Using a condom that has been exposed to excessive heat
- Opening a condom package in a way that damages the condom
- Not squeezing the air out of the tip of the condom before application in order to leave a sufficient reservoir for semen
- Not rolling the condom onto the entire penis
- Using improper lubrication that can damage the condom
- Withdrawing the penis in a way that results in the condom slipping off or spilling semen
- Reusing a condom.

[104] Moreover, these problems can be magnified when condoms are used in less than perfect settings, such as when they are applied in the dark, in small spaces, in awkward positions, or under the influence of intoxicants. To adopt an expression used by the trial judge in this case, in the “real world”, even despite the best of intentions, things can and do go wrong with condom usage.

[105] In fact, this case involves precisely some of those “real world” kinds of circumstances that may lean more heavily toward things going wrong: sexual intercourse taking place in locations that are less than conducive to the careful handling of this piece of latex, including in the dark in cars, parks, bushes, and school yards.

[106] In addition, condom failure incidents are not always obvious. While some condom failure may come to the attention of the sexual participants, this is not always the case. As Dr. Fisman points out:

> You don’t have a biophysics lab present at the bedside after two people have sex so that you can look and see, is there any compromise of the condom’s integrity… and some of it may well be unrecognized because you’re talking about potentially very small quantities of fluid and very small particles.

[107] Indeed, the chances of noticing condom failure might be further minimized where one party to the sexual act has no knowledge that there is a risk of HIV transmission should the condom fail. Where a complainant is unaware of the risk, he or she may not be as vigilant with the condom use as might otherwise be the case.

[108] Again, the circumstances of this case underscore that fact. By way of example, A.C. testified that the appellant usually brought his own condoms, put them on himself and disposed of them. She did not pay much attention to the procedure. In fact, she was not even sure if the condoms contained ejaculate when they came off: “It was dark, so I couldn’t tell. The lights were always off.” As it turns out, unbeknownst to her, those condoms that she paid so little attention to were her sole line of defence against the baseline risk of HIV transmission because the appellant had not started taking antiretroviral medication during the many months while they were engaged in sexual acts.

[109] Accordingly, “correct” usage does not necessarily mean that the condom functioned perfectly. Even in situations where there is a well-intentioned effort to achieve perfect usage, things can and do go wrong.

b. Assessing Risk from a Population Level is Consistent with Epidemiology and the Criminal Law

[110] What the appellant and interveners are really looking for is a legal rule that favours determining the realistic possibility of transmission by looking to the actual effectiveness of condoms at the exact time they are used. As the appellant argued on appeal, it should be for the Crown to prove beyond a reasonable doubt that a condom failed before the criminal law could even possibly apply.

[111] This argument is inconsistent with risk assessment from an epidemiology perspective and is also inconsistent with the legal underpinnings of *Mabior.*

[112] As Dr. Fisman explains, looking to population-level statistics to predict risk at an individual level is the “premise that underpins the entire field of epidemiology” and is “crucial” to predicting “the risk for an individual person.” Any other approach assesses risk from an *ex post facto* perspective, one where the harm arising from the risk has either happened or not. As Dr. Fisman explains:

> [I]t’s very difficult to talk about probabilities when you are talking about an individual, because the event either happens or doesn’t happen with an individual, it’s a 0 or a 1. Whereas in a population we can get into estimation of risks. … Post hoc you know with certainty what happened, but it’s sort of horse-and-barn-door stuff, it’s nonmodifiable, which is why it’s important to have estimates of risk ex-ante.

[113] In contrast, I read Dr. Smith’s evidence as essentially supporting the idea that, for purposes of the criminal law, risk of HIV transmission should only be assessed based upon the “outcome of the event”. When asked about whether population data has some relevance to informing the “predictive probability of transmission” of the virus, he answered: “Well, I think in terms of preventive health education it would, but in terms of just legal system it would not.”

[114] Dr. Smith confirmed that this is his view of “how the legal system should function.” He went even further and provided his opinion that the “legal system” should not be dealing with cases involving only risk of transmission:

> I think that the legal system should not be dealing with cases where there [has] not been transmission. Personally, I think it would be reasonable for the legal system to deal with cases where there has been transmission.

[115] Of course, that is not a scientific or medical conclusion, but a legal one that is antithetical to the reasoning in both *Cuerrier* and *Mabior.* In my view, Dr. Smith’s evidence contains no new information about the effect of condom use on HIV transmission rates; rather, what has changed is his opinion that the criminal law should approach these risks differently than the Supreme Court chose to in those cases.

[116] Although the appellant and interveners do not go quite as far as Dr. Smith by suggesting that only transmission cases should fall within the reach of the criminal law, they heavily rely upon his evidence to advance the position that the risk of transmission should only be looked at from an after-the-fact perspective. They argue that, at its highest, an after-the-fact inquiry should be made into whether the complainant was actually put at risk. This stands in direct opposition to the current forward-looking *Mabior* approach to assessing whether there exists a realistic possibility of HIV transmission at the time when the unwitting sexual partner offers his or her consent to the sexual activity in question.

[117] In my view, their position is really a request to conduct a “case-by-case” approach to risk assessments in HIV non-disclosure cases. That approach was specifically rejected in *Mabior* because of the inherent lack of predictability that would result from any such approach: *Mabior*, at paras. 68-69. Indeed, it is that very kind of approach that led to great uncertainty in the wake of *Cuerrier* and why *Mabior* came along to inject certainty into this complex area of the law.

[118] It is important that the criminal law be predictable. People need to know with some degree of certainty, before they engage in conduct, whether that conduct will be labelled criminal or not. The desire in *Mabior* to provide clarity in the operation of the criminal law is one of the foundational principles upon which the decision rests, and one that pushed toward a clear and easily applied test for when the realistic possibility of transmission of HIV would be negated: *Mabior*, at paras. 14, 19.

[119] The appellant's and interveners' suggestion that the law move toward an assessment of whether there was a risk of transmission of HIV during a specific sexual encounter, based on whether condoms actually slipped, leaked, broke, or otherwise malfunctioned, would return the law in HIV non-disclosure cases to the undesirable world of uncertainty.

[120] Moreover, I do not accept the appellant's suggestion that the criminal law is designed only to address what actually happens as a result of what people do, not the risk they potentially put others at while doing it. Indeed, there are examples of the criminal law addressing its attention to risks before they materialize.

[121] As the respondent points out, drinking and driving and unsafe storage of firearm offences constitute two examples of the criminal law specifically targeting perceived risk of harm before that risk is actually visited upon others.

[122] I do not wish to be taken as suggesting that drinking and driving or unsafe storage of firearms offences are perfect analogies to HIV non-disclosure sexual assault-based offences. There is one important difference between them. When it comes to drinking and driving and unsafe storage of firearms offences, members of the public are not given the choice to voluntarily assume the risks associated with those activities. When it comes to HIV non-disclosure cases, though, members of the public are given that choice. The key is that they need to know there is a risk before they can choose to assume that risk.

[123] HIV non-disclosure cases are therefore targeted at the deception involved in unilaterally placing complainants at risk without giving them the choice to voluntarily assume that risk and decide how to best manage that risk.

[124] To this end, I would add the crime of fraud to this discussion. Indeed, the essential elements of fraud were discussed at some length in *Cuerrier* and, with some adaptation, formed the genesis of the approach to how fraud can vitiate consent in the HIV non-disclosure context: *Cuerrier*, at paras. 114-17. Drawing upon the court's prior authorities setting out the elements of fraud, including reference to *R. v. Théroux*, 1993 CanLII 134 (SCC), [1993] 2 S.C.R. 5, Cory J. emphasized in *Cuerrier* that the "essential elements of fraud are dishonesty, which can include non-disclosure of important facts, and deprivation or risk of deprivation" (emphasis added): at para. 116. In other words, a risk of deprivation to one's economic interests, through dishonest means, is sufficient for fraud. Take away the dishonesty and someone can voluntarily assume the risk of financial harm.

[125] *Cuerrier* took the same risk approach to HIV non-disclosure, by focussing on the risk to the complainant at the time that the consent is dishonestly procured. Take away the dishonesty and someone can voluntarily assume the risk of HIV transmission.

c. Assessing Risk from a Population Level is Consistent with *Charter* Values

[126] *Mabior* reflects an exquisitely difficult balance between the rights of those living with HIV and the rights of those offering their consent to sexual activities without all of the information they need and would like to make that decision.

[127] On the one hand, the court emphasized that the stigma attaching to a criminal conviction in this context should be "reserved for conduct that is highly culpable" in nature: *Mabior,* at para. 19. On the other hand, the court emphasized the *Charter* values of equality, autonomy, privacy, liberty, and bodily integrity, all of which promote respect for sexual participants and their dignity as human beings: see *Mabior*, at para. 45. See also *Ewanchuk*, at paras. 27-28; *Barton*, at paras. 88-90, 109. These are the *Charter* values animating the *Mabior* decision and underpinning the complainant's right to be informed of a partner's HIV status in the circumstances described in *Mabior.*

[128] It is against that backdrop that the court spoke of "[o]ur modern understanding of sexual assault", one that "is based on the preservation of the right to refuse sexual intercourse" and the need to interpret s. 265(3)(c) within that context: *Mabior,* at para. 45.

[129] In my view, the use of population-level statistics to assist in determining the risk of HIV transmission during condom-use-alone sexual intercourse is entirely consistent with our modern notion of consent to sexual activity and what may operate to vitiate that consent.

[130] From a consent perspective, it makes sense to consider the risk of HIV transmission during a sexual act from a forward-looking perspective. After all, if risk is to be looked at after condom failure, then

the complainant has already been put at risk without having voluntarily assumed that risk. This hindsight approach to risk, after the risk has been involuntarily and unknowingly assumed, would do little for the modern-day notion of consent and the preservation of the "right to refuse intercourse". In my view, the *Mabior* rule is about preventing the consenting party from having the risk of contracting an indisputably serious, life-altering disease unilaterally imposed upon him or her in the first place: *Mabior,* at para. 88.

[131] While I accept that HIV is now a manageable disease, it remains incurable and indisputably chronic, such that it could change the entire course of a sexual partner's life: Canadian Consensus Statement, at p. 138; International Consensus Report*,* at s. 2; Department of Justice Report, at pp. 3-6. While AIDS can be avoided, to date, HIV cannot be cured: Department of Justice Report, at p. 3. Among other health complications, HIV requires antiretroviral medication, leaves a person susceptible to other infections because of the immune system impairment, and brings about periods of ill health and disability: Department of Justice Report, at pp. 5-6.

[132] It is only by resorting to population-level statistics that forward-looking risk can be assessed.

3. The Risk of Condom Failure in the Cochrane Review is Not Overinflated

[133] The appellant also argues that the population-level statistics contained in the Cochrane Review are suspect. First, he says that those statistics – as relied upon by the Supreme Court of Canada in *Mabior* and by Dr. Wobeser at trial – are predicated on groups of "always condom users" and "never condom users".

[134] As for the always condom users, the appellant argues that there is likely some social acceptability bias embedded in the statistics because it involves self-reporting, where people will be motivated to suggest they took appropriate precautions prior to becoming seroconcordant (the non-HIV-positive sexual partner moving to a positive status). This would lead to some people reporting using condoms when they did not actually use condoms, causing some instances of transmission from sex without condoms to be recorded as transmission from sex with condoms. That could lead to condoms appearing less effective than they actually are.

[135] The appellant also suggests that there may have been some difficulties with some of the underlying studies informing the Cochrane Review. For instance, in one of the studies, where there had been four seroconversions involving people who claimed to have always used condoms, the authors of that study noted that there had been "improper or incomplete condom use" in a number of the cases. In another study, the appellant suggests that, because of the way in which the seroconversions were assigned to specific time frames, it may be that it had the effect of misclassifying the effectiveness of condoms. He argues that some seroconversions were assigned to timeframes during which the couple reported always using condoms, but transmission may have occurred during an earlier timeframe when they were not using condoms. Again, if this occurred, it would lead to condoms appearing less effective than they actually are.

[136] This argument is rooted in the suggestion that, even if it was right for the Supreme Court to assess the risk of transmission of HIV with the use of population-level statistics, it was wrong to have uncritically accepted the Cochrane Review as accurately containing the condom failure error rate across the population.

[137] The respondent relies upon the evidence of Dr. Yarber, an expert on condom use and failure rates. The appellant challenges Dr. Yarber's numbers, arguing that, in fact, the rates for condom breakage, leakage, slippage, late application, and early removal events are much smaller than he suggests.

[138] The respondent disputes the appellant's characterization of the statistics, claiming they are actually much higher than the appellant suggests. Relying upon a study that Dr. Yarber co-authored, the respondent suggests that condom use errors must be considered in light of studies showing the combined rates for different types of condom failure together, some of which are well over the 20 percent range: *Sanders et al.*, "Condom use errors and problems: a global view" (2012), 9 Sexual Health 81, at p. 90. That is, the chance of the condom slipping *or* breaking *or* otherwise failing – the chance of the condom failing in some way – can be over 20 percent.

[139] I do not intend to address the specific statistics for condom slippage, breakage, leakage, and the like. At the end of the day, in my view, the Cochrane Review relied upon by the Supreme Court in *Mabior* has not been shaken in any meaningful way by the new evidence here.

[140] Indeed, Dr. Smith acknowledged during cross-examination on the reopening application that the Cochrane Review is a meta-analysis that remains "widely respected as a valiant attempt to measure the average risk of transmission in the real world". Dr. Smith also referred to the Liu Study that suggests

much lower rates of transmission with condom use, but the validity of that study has been called into question. Dr. Fisman provides evidence that the study is highly questionable and, in fact, is "out of keeping with scientific consensus": see *Liu*, *et al.*, "Effectiveness of ART and Condom Use for Prevention of Sexual HIV Transmission in Serodiscordant Couples: A Systematic Review and Meta-Analysis" (2014) 9:11 PLoS ONE e111175. "Serodiscordant" means one partner is infected and the other is not.

[141] I agree that the Cochrane Review, as Dr. Smith suggested on the reopening application, is still "widely accepted". Indeed, the Public Health Agency of Canada performed a synthesis of current medical evidence relating to HIV transmission rates published in 2018 and relied in part on data from the Cochrane Review: *Traversy LeMessurier*, *et al.*, "Risk of Sexual Transmission of Human Immunodeficiency Virus with Antiretroviral Therapy, Supressed Viral Load and Condom Use: A Systematic Review" (2018), 190, Can. Med. Assoc. J. E1350. An earlier version of that synthesis was also relied upon by the Department of Justice in determining the rate of HIV transmission when condoms are used alone: Department of Justice Report, at p. 8. The International Consensus Statement also relied on the Cochrane Review: see fns. 17, 22, 69.

[142] According to Dr. Fisman, whose evidence I accept, the Cochrane Review represents a "reasonable" assessment of condom effectiveness across the population, "as imperfect as that is." For every act of vaginal intercourse, the Cochrane Review concluded that condom use resulted in an 80.2 percent relative reduction in HIV transmission, the best-case estimate being 94.2 percent and the worst-case estimate being 35.4 percent. In other words, as Dr. Fisman put it, condoms "could be better than we think they are" or they could be "worse than we think they are." Indeed, the Cochrane Review itself acknowledges that condom effectiveness could be under- or overestimated by the study and, importantly, the Supreme Court of Canada had that evidence before it when *Mabior* was decided.

[143] Even if the reduction rate for the transmission of HIV is slightly higher than what the Cochrane Review suggests, the fact remains that, from an admissibility perspective, that new evidence is not sufficiently cogent to be granted admission.

[144] While the appellant quarrels with the precise reduction in risk of transmission arising from condom use alone, even if he is right, his position cannot succeed. To this end, it is notable that the Supreme Court decided that the potential reduction in baseline HIV transmission rates arising from the taking of antiretroviral medication was in the range of 89 to 96 percent: *Mabior*, at para. 101. Yet the court was not satisfied that even that level of reduction in baseline risk of transmission could qualify as negating the realistic possibility of HIV transmission.

[145] Therefore, even if I were to accept (which I do not), that at a population level, the use of condoms alone reduce the risk of transmission of HIV up to even the 96 percent mark, on the *Mabior* analysis, that would still be insufficient, on its own, to negate the court's view of what constitutes a realistic possibility of transmission.

[146] I conclude this section by making two practical observations in response to the appellant's and interveners' characterization of the *Mabior* decision as criminalizing an "infinitesimal" risk of transmission. They emphasize that the baseline risk of HIV transmission is so "infinitesimal" that it cannot possibly rise to the level of a realistic possibility of harm, let alone when that baseline risk is pulled down by another at least 80 percent through condom use. I note that the appellant and interveners are not alone in that position: Martha Shaffer, "Sex, Lies, and HIV: Mabior and the Concept of Sexual Fraud" (2013), 63 U. Toronto L.J. 466, at pp. 472-73; Isabel Grant, "The Over-Criminalization of Persons with HIV" (2013), 63 U. Toronto L.J. 475, at pp. 479-80.

[147] It is important to note, though, that the argument suggesting that there is only an "infinitesimal" risk of transmission arises from statistics predicated on two things: (a) a per-sex-act consideration of risk; and (b) only the baseline risk relating to vaginal-penile intercourse.

[148] First, the baseline statistic for risk of transmission in *Mabior* is based upon a single act of vaginal-penile intercourse. As pointed out by Dr. Wobeser, though, that risk repeats itself with every repeated act of sexual intercourse. Therefore, even if the per-act baseline risk, as reduced by condom use, could be called "infinitesimal", one cannot lose sight of the fact that the risk adds up over time. In other words, even if the risk of engaging in a behaviour with an infected partner once could be called infinitesimal, when that behaviour is repeated, so too is the risk of transmission.

[149] As Dr. Fisman explained, the risk is "cumulative with each sexual act", meaning that following a number of sex acts involving the same serodiscordant couple, the "Bernoulli (or coin-toss) model" would apply. The "risk of the event occurring at least once would be estimated using a formula" that applies an "exponent equivalent to the number of sex acts that have occurred". Put simply, the risk of transmission exponentially increases with each sexual act involving the same serodiscordant couple.

[150] In my view, the repeated risk of harm that comes with each act of sexual intercourse between the same serodiscordant couple partially informs the *Mabior* rule that condom use alone does not negate the "realistic possibility of transmission". While some HIV non-disclosure cases involve one-time encounters, others involve repeated acts of sexual intercourse where there is no disclosure made to the unwitting partner, such as the acts of vaginal sex with A.G. and A.C. in this case. Clearly, the cumulative risk for these complainants rose with each act of intercourse.

[151] Second, I would make the observation that, when it comes to sexual intercourse, the baseline transmission rates differ somewhat significantly between vaginal and anal intercourse. One systemic review, adopted in the Department of Justice Report, at p. 10, places the baseline transmission rate for "receptive vaginal intercourse" (risk to the receptive partner) at 8 in 10,000 (0.08 percent), while it places the transmission rate of "receptive anal intercourse" at 138 in 10,000 (1.38 percent). See also International Consensus Statement, at ss. 2.3.2. and 2.3.3.

[152] In my view, these two factors, cumulative risk over many sex acts, and differing baseline risks depending upon the nature of the sex acts, informs the wisdom of the *Mabior* approach in creating a singular, easy-to-understand, and easy-to-apply rule for the application of the criminal law. Under the present *Mabior* regime, the criminal law cannot apply differently based upon the nature of a sexual act or the number of times those acts take place within the same serodiscordant couple. Any other approach would carry serious implications in terms of equality and return this already complex area of the law to the world of uncertainty.

[153] Accordingly, while the statistical backdrop for the *Mabior* decision may be at the low end of what is meant by a realistic possibility of transmission, there are other scenarios to which the statistical backdrop looks much different.

IV. Policy Reasons to Change *Mabior*

[154] I will conclude by addressing the interveners' arguments about policy. As they say, it is "bad public policy to criminalize people who use condoms." They advance four arguments in support of that position. They maintain that the criminalization of HIV non-disclosure where condoms are used:

- is too blunt an instrument because the HIV-positive person's conduct is not truly blameworthy in nature, particularly given that the risk of HIV transmission in these circumstances is non-existent or negligible at worst;
- ignores scientific evidence and results in "state-sanctioned stigma and discrimination against people living with HIV";
- has the effect of contributing to a broad societal misunderstanding about HIV and serves to exacerbate the stigma surrounding the disease, all of which can work to the detriment of public health; and
- compounds the disadvantage of already significantly disadvantaged groups.

[155] There is no doubt that the criminal law is the bluntest of instruments, properly reserved for only those situations where conduct is so morally blameworthy that it deserves to be labelled "criminal".

[156] Nor can there be any doubt that the stigma associated with a criminal conviction only compounds the difficulties of those living with HIV, an already vulnerable group, many of whom come from historically marginalized and disadvantaged situations: See e.g. Department of Justice Report, at p. 4.

[157] The fact is that there are many different models for how to approach HIV non-disclosure cases. Some of those other models were reviewed by the Supreme Court of Canada in *Mabior*: at paras. 49-55. And, as noted in *Mabior,* at para. 51, there are few jurisdictions that criminalize deception that only exposes a partner to the risk of transmission (as opposed to actual transmission).

[158] Not only is the deception that exposes a sexual partner to a risk of transmission criminalized in Canada, but the most frequently chosen path of prosecution is by way of the most serious sexual offence known to law: aggravated sexual assault, an offence punishable by up to life in prison.

[159] Although this appeal raises the singular issue of the effectiveness of condoms at preventing HIV transmission, there is much to be said for the fact that other things may have changed since *Mabior*. A prime example of change involves the current understanding around suppressed and undetectable viral loads. This significant change is reflected in the policies of some Attorneys General in Canada not to prosecute matters involving these circumstances. There are others, like the federal Attorney General, who have also started to put in place specific condom-related prosecution policies, directing that, as a

"general" rule, there be no prosecutions in situations where condoms are used as long as there are no other risk factors present.

[160] The ability of the common law to adapt is important in this context. Even so, the interveners' arguments call upon this court to overturn the clear legal result in *Mabior* based upon policy arguments.

[161] While there may come a day where there is a reconsideration of the intersection between the law of aggravated sexual assault and HIV non-disclosure risk of transmission cases, this is not that case. The sole issue raised in this appeal relates to the suggestion that, since *Mabior,* there have been changes to how we should understand the effectiveness of condoms at preventing HIV transmission. To that end, I adopt the trial judge's observation that "when the scientific evidence as a whole is examined with respect to condom use in real life situations, nothing has changed in the past five years from the time *Mabior* was decided in 2012 to the present day".

[162] The *Mabior* decision reflects the Supreme Court's appreciation for the fact that perfectly operating latex condoms provide a perfect barrier to the transmission of HIV. It also reflects the court's understanding that sex happens in the real world and that, in that world, human error and condom failure are concerns across the population. It also reflects the court's decision to criminalize the risk of transmission from a forward-looking perspective, one that takes into account the need for certainty in the criminal law. Finally, it accommodates an interpretation of s. 265(3)(c) of the *Criminal Code* that is consistent with our modern notion of consent to sexual activity.

[163] In my view, there is nothing in the new evidence that reveals a change in the facts upon which *Mabior's* legal reasoning rests. The fresh evidence on appeal is not cogent and is not admissible. The trial judge did not err in excluding Dr. Smith's evidence on the reopening application.

CONCLUSION

[164] On consent, I would amend count 3 on the indictment to reflect the offence commencing on October 20, 2013 and continuing to June 24, 2014.

[165] I would dismiss the fresh evidence application. I would dismiss the appeal.

Released: "P.L." August 5, 2020

"Fairburn J.A."
"I agree. P. Lauwers J.A."
"I agree. Gary Trotter J.A."

---

[1] Although the *Mabior* decision does not specifically define what constitutes a low viral load, it describes a viral load of less than 1,500 copies of HIV present in a millilitre of blood as "low": at para. 100.
[2] Although the complainants in this case testified about also having had condomless oral sex with the appellant, the trial judge's reasons focus on the risks of transmission associated with the acts of vaginal intercourse. Therefore, these reasons are similarly focused on the acts of vaginal sexual intercourse.
[3] The appellant and interveners also draw this court's attention to the trial decision in *Thompson,* what they put forward as the only post-*Mabior* decision that suggests that condom-use alone (combined with no ejaculation) is sufficient to negate the realistic possibility of HIV transmission.
[4] The respondent also raises a concern about the final prong of the *Palmer-Truscott* test: diligence. In my view, there is no need to address that concern given that the appeal fails on the cogency element.
[5] See, for instance, cases that include convictions for offences in addition to aggravated sexual assault: *R. v. Iamkhong*, 2009 ONCA 478, 250 O.A.C. 220; *R. v. Booth*, 2005 ABPC 137, 382 A.R. 116; *R v. Boone*, 2019 ONCA 652; *R. v. Aziga*, 2011 ONSC 4592, appeal as of right filed. See also, Department of Justice Report, at pp. 11 and 13.
[6] *R. v. D.C.*, 2012 SCC 42, [2012] 2 S.C.R. 626, was released at the same time as *Mabior,* simply applying the *Mabior* test to the facts of that case.
[7] The new evidence on appeal is focused upon male condoms. As this case involved the use of male condoms, I remain similarly focused.

Key Messages/Points

- Only respiratory tuberculosis (TB), with limited exceptions, is infectious; contact follow-up should be carried out for both sputum smear-negative and smear-positive cases. The objective of contact follow-up is to identify and treat any secondary cases, and to identify contacts with latent TB infection (LTBI) in order to offer preventive treatment. Source-case investigation is recommended for children under 5 years old with a diagnosis of active TB disease.
- Interviews with the infectious case to identify contacts should include questions about locations/activities of potential exposure as well as specific named contacts. The discussion of site-based, social network contact investigation as well as the section on contact follow-up in homeless populations has been expanded from the 6th edition of the Standards.
- Prioritization of contact follow-up is recommended by the infectiousness of the source case, extent of exposure and immunologic vulnerability of those exposed. Thus, the most effort is put into contacts who are most at risk of being infected and/or most at risk of developing active TB (tuberculosis) disease if infected.
- The classic concentric-circle approach to contact follow-up is no longer recommended. Rather, the initial follow-up should include non-household contacts from the outset when case infectiousness and contact vulnerability indicate, rather than waiting.
- Contacts may be grouped as follows:

  High priority
  - household contacts plus close non-household contacts who are immunologically vulnerable, such as children under 5 years.

Medium priority

- close non-household contacts with daily or almost daily exposure, including those at school and work.

Low priority

- casual contacts with lower amounts of exposure.

- For smear-positive/cavitary/laryngeal TB (tuberculosis), it is recommended that the initial contact follow-up include both high- and medium-priority contacts. For smear-negative, non-cavitary pulmonary TB (tuberculosis), the initial contact follow-up should be for high-priority contacts only. In both situations, contact investigation is iterative: it should be expanded if the initial follow-up results indicate that transmission has occurred.
- A single evaluation at least 8 weeks after the end of exposure (with tuberculin skin testing [TST (tuberculin skin testing)] and symptom assessment) is recommended in most non-household contact settings, in order to maximize participation and minimize overdiagnosis of "conversion" related to boosting. Initial plus 8 week post-exposure TST (tuberculin skin testing) is recommended for household and other high-priority contacts. Two-step TST (tuberculin skin testing) is not recommended in the setting of a contact investigation.
- TST (tuberculin skin testing) is no longer recommended as a primary assessment tool in the contact follow-up of elderly residents in long-term care, in whom it is less reliable and for many of whom the risks of treatment of LTBI (latent TB infection) in old age will outweigh any benefit. The focus for these individuals should be on early detection of secondary cases.

Introduction

The first priority of TB (tuberculosis) control programs is always recommended to be the early identification and successful treatment of all TB (tuberculosis) cases. This is because treatment rapidly reduces the risk of TB (tuberculosis) transmission to others. The next priority should be evaluation and follow-up of close contacts of active cases in order to identify secondary cases, source cases in some situations and those with recently acquired LTBI (latent TB infection), to offer this group treatment [1-3]. Typically, 1%-2% of close contacts are found to have active disease at the time of contact investigation [4].In addition, about 5% of newly infected contacts will develop active disease within 2 years of exposure [5-8]. TB (tuberculosis) programs in North America typically find a median of 4 (average 6) close contacts for each TB (tuberculosis) case [4] [9].

Reporting of active TB (tuberculosis) is required in all Canadian jurisdictions. In part this is to ensure that contact investigation can be carried out quickly, in an organized, collaborative manner.

With limited exceptions, only TB in the respiratory tract is infectious and requires contact investigationFootnote 10.Patients who present with nonrespiratory disease can also have concomitant respiratory involvement; thus it is important for all TB patients to have chest radiography (and sputum testing if there are any respiratory symptoms or chest x-ray abnormalities) as part of their medical work-up. Patients with miliary TB are often culture-positive on sputum or other airway secretions and occasionally smear-positiveFootnote 11.Induced sputum cultures have been found to be positive in up to 50% of cases of pleural TB, even in the absence of pulmonary disease on chest x-rayFootnote 12.Therefore, both miliary and pleural TB should also be considered as potentially contagious.

Factors associated with TB transmission are outlined in Chapter 2, Pathogenesis and Transmission of Tuberculosis. Cases who are sputum smear-positive or have cavitary disease on chest x-ray are significantly more infectious than smear-negative or non-cavitary casesFootnote 2 Footnote 8 Footnote 9. Adolescence, adult age, coughing, sneezing and singing also increase the risk of transmissionFootnote 1.Transmission is rarely thought to occur outdoors; however, indoor environments that are poorly ventilated, dark and damp can lead to increased concentration and survival of Mycobacterium tuberculosisFootnote 13 Footnote 14. In infected contacts who are vulnerable because of young age (under 5 years), HIV or other causes of significant immune suppression infection may progress quickly to active disease;Footnote 8 early diagnosis often depends on good contact follow-up.

Contact investigation often demands considerable time, expertise and coordination. It is usually best carried out by public health/ TB (tuberculosis) control authorities in collaboration with treating clinicians and other providers. Anxiety, stigma and lack of knowledge about TB (tuberculosis) among those exposed may be major issues. Provision of clear, credible and consistent information about TB (tuberculosis) and the contact follow-up plan is important.

Definitions

Index case: the first case or initial active case from which the process of contact investigation begins.

Source case: the person who was the original source of infection for secondary case(s) or contacts. The source case can be, but is not necessarily, the index case.

Contact: a person identified as having been exposed to an active case of disease. The closeness and duration of exposure usually corresponds with the risk of becoming infected.

Objectives of Contact Investigation

Contact investigation has three main objectives. In order of priority these are as follows:

1. Identify and initiate treatment of secondary cases of active TB (tuberculosis) disease.
2. Identify and treat the source case who infected the index case, if the index case is under 5 years old.
3. Identify contacts with LTBI (latent TB infection) in order to offer preventive treatment.

Principles of Contact Investigation

Prioritize the Work

This is the most important principle. It is advisable to prioritize by the infectiousness of the source case, extent of exposure and immunologic vulnerability of those exposed. Thus, the most effort can be put into contacts who are most at risk of being infected and/or most at risk of developing active TB (tuberculosis) disease if infected. Contact investigation is iterative: it should be expanded if initial follow-up results indicate that transmission has occurred.

Rapid Initiation of Contact Investigation

Rapid evaluation of close contacts allows prompt identification of those who already have active disease and, if active disease has been excluded, allows initiation of treatment of LTBI (latent TB infection) for newly infected contacts before disease occurs.

As soon as a suspected case of TB (tuberculosis) has been reported, it is advisable for public health authorities to ensure that all the medical investigations to confirm the diagnosis and determine the degree of infectiousness are under way (chest radiography plus sputum collection as necessary, even for patients with suspected extrapulmonary TB (tuberculosis)) and that the patient is in airborne infection isolation. Initiation of adequate TB (tuberculosis) treatment is the most effective way to rapidly decrease infectiousness and the risk to others. If the clinical suspicion of pulmonary TB (tuberculosis) is sufficiently strong to begin TB (tuberculosis) treatment pending microbiologic confirmation, then investigation of household contacts should also begin promptly, especially for any children under 5 years old, HIV (human immunodeficiency virus)-infected contacts and others at high risk of disease progression if infected [10].A positive nucleic acid amplification test result is sufficient grounds to begin contact investigation (refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance). Investigation of contacts beyond the high-priority group (refer below) should always await microbiologic confirmation of the diagnosis.

Assessment of Transmission Risk

Infectiousness of the index case

The single greatest factor determining the extent of contact investigation is the degree of infectiousness of the index case. Neither drug-resistant TB nor coinfection with HIV increases the infectiousness of the case; therefore, the recommended approach and prioritization of the contact investigation is the same. However, treatment of LTBI among contacts should be guided by the drug sensitivity pattern of the source case.

Sputum status is the most reliable indicator of infectiousness. The "worst" (i.e. most positive) result is used to evaluate infectiousness [15].Cases of laryngeal TB (tuberculosis) are considered four to five times more contagious than smear-positive pulmonary cases, as they are likely to have a large number of bacteria due to extensive concurrent pulmonary disease [1] [16] [17].

Cavitary disease on chest x-ray has been repeatedly linked to higher infectiousness, independent of smear status. Chest CT (computed tomography) may detect smaller, early cavitation that is not apparent on the chest x-ray; however, it is not clear whether these individuals are as infectious as those who have cavitation visible on chest x-rayFootnote 10.

Coughing is the least reliable indicator of infectiousness but is generally linked to it, particularly within households. There are several well-documented clusters of TB (tuberculosis) transmission related to cough-inducing medical procedures and to smoking crack cocaine [18].Singing and similar activities (e.g. playing wind instruments) are also associated with increased risk of transmission [19].

In general, children under age 10 with TB (tuberculosis) are not considered infectious. However, in unusual circumstances, even very small children can transmit TB (tuberculosis) - for example, if there has been contamination and inadequate cleaning of respiratory equipment [20].By contrast, adolescents can be very effective transmitters of TB (tuberculosis), partly because they can have extensive disease by the time it is diagnosed, and particularly because in high school they can have large numbers of contacts [21] [22]. It is recommended that any child presenting with adult-type pulmonary TB (tuberculosis) (cough, cavitation on chest x-ray, smear-positive sputum) should be considered infectious and contact investigation undertaken.

Source case investigation

When active TB (whether pulmonary or extrapulmonary) is diagnosed in any child under 5 years old, an immediate search for an infectious source case close to the child is recommendedFootnote 10.Most often the source case is an adolescent or adult in the household, or other care-giver. Source case investigation is also recommended when a cluster of TST conversions is identified in an institutional setting with no known source case. However, source case investigations usually give very low yield; even for young children a source case is identified

in less than half of investigationsFootnote 10 Footnote 23. Source-case investigation is not recommended for adult TB cases, nor for children or adults who are well but have a positive TST result on a routine screening (outside of an institutional cluster of TST conversions, as above).

Nonrespiratory TB is considered noninfectious, so long as concurrent pulmonary disease has been ruled out; no contact follow-up is necessary. Rare exceptions involve aerosolizing medical procedures (e.g. autopsy, high-pressure irrigation of draining TB abscesses). Source-case investigations for nonrespiratory TB are not recommended other than for children under 5 years old, as aboveFootnote 10.

Likely period of infectiousness

Cases of pulmonary TB (tuberculosis) are generally considered to become infectious at the time of onset of cough or worsening of a baseline cough. If no cough is reported or if the duration is difficult to determine, the onset of other symptoms attributable to TB (tuberculosis) may be used to estimate the onset of infectiousness. In practice, however, it is often difficult to know with certainty when symptoms began.

Generally, priority should always be given to contact tracing during the period when the TB (tuberculosis) patient had respiratory symptoms (e.g. a cough). However, guidelines published by the US Centers for Disease Control and Prevention [10] recommend that the patient with smear-positive or symptomatic disease should be considered to have been infectious for 3 months before onset of respiratory symptoms or the first positive finding consistent with TB (tuberculosis), whichever is longer. Asymptomatic cases with a negative smear and no cavities seen on chest x-ray should be considered infectious 4 weeks before the date that TB (tuberculosis) was suspected. However, these guidelines are based on expert opinion rather than clear epidemiologic evidence.

For contact follow-up purposes, the period of infectiousness ends when the index case is in effective airborne isolation from others (this may be before or after diagnosis) or is no longer infectious, whichever comes first. Refer to Chapter 15, Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings, for a description of when isolation may be discontinued for a suspected or confirmed TB (tuberculosis) case.

Degree of exposure to the index case

The interview of an infectious TB (tuberculosis) patient for contact tracing is one of the most important parts of the investigation. It takes considerable skill and is most successful when done by staff with training/experience in public health interview techniques [24].Trust and rapport are important for full disclosure, and the initial interview can also lay the foundation for long-term adherence to TB (tuberculosis) treatment. Face-to-face interviewing, in privacy, is ideal. Most TB

(tuberculosis) patients in Canada were born in countries with high TB (tuberculosis) incidence or in First Nations/Inuit communities (refer to Chapter 1, Epidemiology of Tuberculosis in Canada), so language and cultural perceptions about TB (tuberculosis) and health are very important. Interviews are best carried out in the language the patient is most comfortable with. It is recommended that a professional interpreter or an objective third party (not a family member) be used for interpretation if possible, either in person or participating by telephone. Interviewers should always be respectful and sensitive to patient concerns and beliefs about TB (tuberculosis), should incorporate education about TB (tuberculosis) and stress the confidentiality of contact investigations. Note that legislation may permit or require release of information about the case's diagnosis to specific individuals (e.g. to public health authorities) or in specific circumstances. For example, although precautions can be taken to avoid identification of the case in public or to contacts, some information may have to be shared with selected individuals (e.g. a school principal) in order to identify or reach contacts and ensure that they too get the medical follow-up they need.

Ideally, the treating physician and laboratory should report all new or suspect cases of TB (tuberculosis) to the appropriate public health authority within 48 hours. The first public health communication with a new infectious patient (and/or the health care providers if the patient is hospitalized) should ideally begin within 1 calendar day of the case being notified. The purpose of this brief initial communication is to achieve adequate airborne isolation, provide any urgent support, identify the household contacts and direct any who are ill to immediate TB (tuberculosis) assessment. Interviewing to determine the full set of contacts should be initiated within 3 working days. Interviewing is usually best extended over two (or more) sessions, a week or more apart, as the patient becomes more familiar with public health staff, and the initial stress and anxiety over the diagnosis are resolving. Proxy or supplemental interviews (ideally with patient permission) with family, close friends, coworkers, etc., may be helpful if patients are unable or unwilling to participate. It is important to include questions about the places where the case spends time regularly, not just names of individual people, and to get contact details whenever possible (name, alias/nickname, phone, address, email, age, nature of interaction).

Interviews to identify contacts should include the following information:

- Any contact with children and their ages
- Any contact with immunosuppressed people (HIV (human immunodeficiency virus) positive, cancer patients, etc.)
- Description of the household/congregate setting; household contacts and their ages (includes anyone who regularly sleeps in the home)
- Close friends and relatives who are seen at least once per week - how often, for how long?

- Work or school location and description of setting (type of work, size of room, ventilation, etc.)
- Transportation to work/school - bus, car-pool, etc.
- Place of worship, clubs, sports teams, recreation programs or hobbies
- Any other places or groups the case has regularly been in or with while infectious
- Any contacts who are ill with potential TB (tuberculosis) symptoms or who have known TB (tuberculosis)
- Any major events (e.g. weddings, funerals, parties) the case attended while infectious
- Any recent travel or visitors staying at the home within the previous 2 years - if so obtain details

A site visit to assess the home is strongly recommended, even if the initial interview is carried out in hospital (for feasibility of home isolation, identification of additional household contacts, identification of any social/practical issues relevant to treatment adherence, etc.). Site visits to the school or workplace and other exposure locations are also very helpful to make contact follow-up decisions (environmental characteristics such as size, layout, use of the space and ventilation; interviews with a direct supervisor can help to identify potential contacts). Discretion is important, as a site visit may precipitate unnecessary anxiety and/or lead to a breakdown of confidentiality and repercussions for the case. In this regard, it is advisable to arrange site visits directly with senior personnel, such as a school principal, division manager or occupational health manager and emphasize with them the importance of maintaining confidentiality as much as possible. Refer to Site-based screening below.

There are so many variables in TB transmission that it is very difficult to quantify the amount of exposure that constitutes a significant riskFootnote 25.In theory, there is no amount of exposure to infectious TB that is absolutely without risk; in practice, each case should be evaluated on its specific characteristics. For context, one study of almost 3,000 contacts demonstrated that TST-positive contacts had a mean of 65 hours more exposure than TST-negative contactsFootnote 26.By contrast, in an outbreak investigation among university students exposed to an index case with laryngeal and cavitary pulmonary TB, the risk of infection per hour of exposure was over 1% in many classes; some contacts converted with as little as 3-4 hours of exposure per weekFootnote 27.Exposure in cramped, ill-ventilated spaces may lead to transmission in much shorter exposure times, and genetic fingerprinting has occasionally discovered apparent transmission following close but very brief exposureFootnote 28.

Organized and Systematic Contact Investigation: Prioritizing Contacts

An organized, systematic approach will allow the TB program to put the most effort into those contacts at most risk. In the 6th edition of the Standards, the traditional "concentric circle" approach to prioritizing TB contact follow-up emphasized starting with contacts who have the most exposure (e.g. household contacts) and expanding stepwise to those with progressively less exposure whenever there is evidence of transmission, until the level of TB infection reaches background rates. However, this approach does not take into account contacts who may have less extensive exposure but, if infected, are immunologically vulnerable to rapid development of active TB. It can also lead to long delays in appropriate contact follow-up when the index case is already known to be highly infectious. A fundamental difficulty is that transmission can be very difficult to evaluate when the background rate of positive TST results is unknown or is high (for example, people who immigrated to Canada from high-incidence countries). This is often the case in Canada, where the majority of TB cases - and many of their close contacts - are foreign-born; it is also the context in many Aboriginal communities. A strictly concentric circle approach can also be difficult to apply in complex congregate settingsFootnote 22 Footnote 29.

Instead, recommended priorities for initial contact follow-up and criteria for expansion are outlined below. These are guidelines: it is always important to consider the specific circumstances, work from first principles of TB (tuberculosis) transmission and re-evaluate according to the results of the investigation as they become available.

For TB (tuberculosis) follow-up purposes, contacts may be categorized as follows:

Household contacts are those who regularly sleep in the same household as the infectious case on an ongoing basis (e.g. three or more times per week). This may include members of an extended family, room-mates, boarders, "couch-surfers," etc. Household members often have the greatest exposure to the TB (tuberculosis) case [8] [22] [26].

Close non-household contacts are those who have regular, extensive contact with the index case and share breathing space daily or almost daily but do not sleep in the same household most of the time. Close non-household contacts may include caregivers, regular sexual partners, close friends or extended family. They also include daycare and primary/secondary school classroom contacts, and coworkers who work in close proximity, particularly in small rooms. The amount of time that high school classmates spend in the same room as the case will depend on the number of shared courses; prioritize those who share the most actual time together. Similarly, in almost all workplaces it is possible (and important) to define the group of colleagues who spend the most time in the same air space as the case. Regular contacts in specialized health care settings such as dialysis units or rehabilitation programs may also qualify. It is not social closeness to the

TB case but, rather, the amount of time in a shared airspace that is the critical issue. For example, computer personnel may report working very closely with others in their group but spend little time together in shared air space if the work is largely done electronically.

Casual contacts are those who spend time regularly but less frequently with the infectious case. These may include high school classmates who share fewer courses with the case, classmates in college/university classes, less exposed colleagues at work; members of a club, team, weekly children's play-group or other social/recreational/religious group; extended family members who are seen occasionally; other students on a school bus.

Community contacts are those living in the same community or attending the same school or workplace but in a different classroom or area of the workplace. Individuals who have only transient or occasional exposure are in this group.

The highest priority contacts are those with the most exposure and those with the highest risk of progression to active TB (tuberculosis) if infected, as follows:

- household contacts, including those exposed as "household members" in congregate settings such as homeless shelters, jails and long-term care facilities (generally, room-mates or cell-mates)
- contacts who are close non-household or casual contacts AND who are at high risk of progression of LTBI (latent TB infection) to TB (tuberculosis) disease, e.g. age under 5 years, HIV (human immunodeficiency virus), dialysis, transplant, silicosis (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, and Chapter 6, Treatment of Latent Tuberculosis Infection)
- contacts exposed (i.e. without an N95 mask) during bronchoscopy, sputum induction, autopsy or other aerosolizing medical procedures (refer to Chapter 15).

Medium-priority contacts are the close non-household contacts who are not at high risk of rapid progression from LTBI (latent TB infection) to active TB (tuberculosis). Most close non-household contacts fall into the medium-priority group.

Casual contacts are low priority. It is generally recommended that the investigation be expanded to this group only if there is evidence of transmission or the case is considered to be extremely infectious (e.g. laryngeal TB, refer to Chapter 2, Transmission and Pathogenesis of Tuberculosis). However, the specific circumstances should always be considered. For example, a choir group meeting once per week may pose significantly more risk than a weekly outdoor soccer game; children riding on long daily school bus routes in winter, when windows are usually closed, may have considerable exposureFootnote 30.

It is rare for community contacts to need investigation (e.g. an entire school beyond the exposed classrooms, general customers of grocery stores or fast-food restaurants)Footnote 31.Such an extensive investigation should be undertaken only in very unusual circumstances; consultation with experienced public health colleagues is advised.

For respiratory TB (tuberculosis) cases who are sputum smear-positive, or have cavitary disease, or have laryngeal TB (tuberculosis), the initial investigation should include both high priority and medium priority contacts. If there is evidence of transmission (refer below) within these two groups, consideration should be given to expanding contact follow up to casual contacts. *For laryngeal TB (tuberculosis)*, also consider including any casual contacts (social/recreational groups, etc.) from the outset [10].

For smear negative respiratory TB (tuberculosis) cases, household members should always be assessed in the initial contact investigation, along with any other high-priority contacts. However, investigation should be expanded to medium-priority contacts (e.g. other close non-household contacts) only if there is evidence of transmission [10] [15].

High-priority contacts should be assessed for both smear-negative and smear-positive cases. Whenever possible, initial assessment (TST (tuberculin skin testing) and symptom assessment, then medical assessment and chest radiography if the TST (tuberculin skin testing) result is ≥5 mm or the patient is symptomatic, plus sputum if symptomatic or the chest x-ray is abnormal) of the high-priority contacts should begin within 7 working days of their being identified as contacts and be completed within 1 month. High-priority contacts should ideally have both an initial and a second TST (tuberculin skin testing) (at least 8 weeks from the last day of exposure) to identify conversion. Participation rates for TB (tuberculosis) skin testing may be higher if it is done directly by TB (tuberculosis) program staff, at home or at a TB (tuberculosis) clinic [10].

Especially among non-household contacts, participation rates often drop significantly between initial and post-8-week screenings as the level of initial concern declines. Thus, in most non-household settings it is most practical to aim for a single round of screening after 8 weeks from the break in contact. In populations in which many people have prior exposure to TB (tuberculosis) or BCG vaccination (e.g. immigrants from high-incidence countries), this also avoids false TST (tuberculin skin testing) "conversion" related to boosting. If casual contacts are investigated, only a single TST (tuberculin skin testing) after 8 weeks from the last day of exposure is recommended [32].

Expanding Contact Investigation

Transmission is considered to have occurred if a secondary case is identified in any contact, if there are any TST (tuberculin skin testing) converters, if the prevalence rate of TST (tuberculin skin testing) >10 mm among contacts is significantly higher than expected (for example, 60% among contacts when the expected prevalence rate is 40%, refer to Table 1) or if a child contact under age 5 years is infected without another probable source. TST (tuberculin skin testing) results in Canadian-born contacts, particularly children, may be the most useful in assessing transmission. A TST (tuberculin skin testing) result is considered positive in contacts with a TST (tuberculin skin testing) result of 5 mm or greater or in converters who have had an increase of 6 mm from a previous TST (tuberculin skin testing) result of 5-9 mm. A history of BCG vaccination does not alter the interpretation of the TST (tuberculin skin testing) results (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, for more information). When there is evidence of transmission, the contact investigation should first address any high-priority contacts who have not yet been assessed and investigate moderate-priority contacts if this has not already been done. Consideration should then be given to expanding to casual contacts. Genotyping to compare index and secondary cases should be requested, but further contact tracing should not be delayed while results are pending.

Table 1. Expected range of prevalence of TST (tuberculin skin testing) results (≥10 mm induration) in various Canadian populations [A]

Population	Expected range of prevalence of TST (tuberculin skin testing) ≥10 mm (%)		
	BCG status not specified	BCG vaccinated	Non-BCG vaccinated
Canadian-born non-Aboriginal children [B]	N/A	N/A	1-3
Canadian-born non-Aboriginal adults	13	65	7
Canadian-born Aboriginal children	5-29	6-25	0-5
Canadian-born Aboriginal adults	14-30	29-50	17-21
Foreign-born children	15-23	N/A	N/A
Foreign-born adults	53-61	73	25
Health care workers	11-46	27-77	5-18
Residents of long-term care facilities (age ≥60)	6-25	71	18
Residents of homeless shelters	45	N/A	N/A
Correctional facility inmates	12-72	90	63
Correctional facility staff	5-33	N/A	N/A

Population	Expected range of prevalence of TST (tuberculin skin testing) ≥10 mm (%)		
	BCG status not specified	**BCG vaccinated**	**Non-BCG vaccinated**
Injection drug users (TST (tuberculin skin testing) ≥5 mm)	31	N/A	N/A
Injection drug users (TST (tuberculin skin testing) ≥10 mm)	66	N/A	N/A
People with pre-existing medical conditions (TST (tuberculin skin testing) ≥5 mm)	14-24	N/A	N/A
People with pre-existing medical conditions (TST (tuberculin skin testing) ≥10 mm)	18-26	N/A	N/A
Overall community	6-36	N/A	N/A

N/A = Non applicable

A Based on *Compendium* of Latent Tuberculosis Infection (*LTBI (latent TB infection)*) Prevalence Rates in Canada, Public Health Agency of Canada, 2012 (for an electronic copy of the full compendium, contact *TB_surveillance@phac-aspc.gc.ca)*.

B Although the Aboriginal status was not specified in the study, it was assumed that the vast majority of the reference population belonged to the Canadian-born non-Aboriginal category.

There is often pressure on a public health department or physician to initiate widespread contact investigation - e.g. to an entire school - from the outset. If this is done, however, it is often impossible to interpret the results of a positive TST (tuberculin skin testing) result (or interferon gamma release assay [IGRA (Interferon Gamma Release Assay)]) in individual patients. Contacts may then be mistakenly identified as recently infected and the investigation expanded yet further. This can also lead to widespread concern about the risk of transmission to community contacts. If expansion of the investigation beyond high- and medium-priority groups is considered, the decision should be based on evaluation of any evidence of transmission in the initial investigation, the probability of finding infected individuals among less exposed contacts and the likelihood that these casual contacts will follow up on screening and LTBI (latent TB infection) treatment recommendations. Contacts with less exposure have a positive TST (tuberculin skin testing) prevalence rate that is usually four to eight times less

than that among household contacts [4] [8] [33] [34]. Also, contact participation rates in TB (tuberculosis) screening, follow-up and LTBI (latent TB infection) treatment tend to be lower in less close contacts, contacts of less infectious cases and in adults compared with children [35].

Additional Approaches to Contact Tracing

DNA genotype fingerprinting:

DNA fingerprinting is available to all Canadian TB control programs, on request or routinely, through the public health laboratories. It can be a useful adjunct to epidemiologic investigations to confirm or disprove suspected linkages between cases and to evaluate potential specimen mix-upsFootnote 36 Footnote 37. It can be particularly helpful in populations in which contact follow-up is challenging and resource intensive, such as the homeless; routine use of fingerprinting for homeless cases may identify linkages not otherwise suspected and guide expanded contact investigationFootnote 38 Footnote 39. Rapid fingerprinting techniques (spoligotyping, MIRU [Mycobacterium Interspersed Repetitive Units]) are helpful to quickly identify or rule out potential new cases in evolving clusters or outbreaks. Fingerprinting can also be very useful, and reassuring, in the evaluation of potential clusters if the results do not show matching outside known household secondary cases.

Location-based contact investigation and social network analysis:

All cases should routinely be asked about the locations where they spend time. Particularly when infectious cases are unable or unwilling to name specific contacts, or when cases are occurring without identifiable exposure risks or sources, identifying locations where the case spent time may be more productive than traditional name-based approaches [40].Investigations have identified transmission occurring at bars, crack use sites, etc., [41-43] which can then be targeted for broad location-based screening clinics and TB (tuberculosis) education/outreach. Epidemiologic links among cases can be enhanced when questions about common locations are included in case interviews.

Social networks analysis examines the social relationships between cases and contacts to identify settings and behaviours that characterize transmission events. Social network analysis has been extensively studied in sexually transmitted infections and more recently in the study of TB (tuberculosis) outbreaks [40] [43-45]. Formal social network analysis, using special computer software, may be particularly helpful in outbreaks (refer to Pajek-Program for Large Network Analysis).

Site-base screening and congregate settings:

In some settings, it is far more practical and feasible to carry out contact investigation for an entire group (such as a class at school or coworkers in a work setting) than attempt to identify the specific individuals who were most exposed. Practical factors, such as the ability to reliably measure the degree of exposure of different individuals in the setting, the administrative ability to provide efficient testing and TB (tuberculosis) education, and the ramifications of extending the investigation to a larger group later if it becomes necessary, should be taken into account in deciding on the extent and number of people to be tested. Similarly, in certain settings (e.g. shelters for the homeless) in which contacts may be difficult to identify or to find, it may be helpful to do wider testing from the outset.

School, workplace and other congregate setting investigations are usually best carried out on site. This leads to higher participation rates among contacts, better communication and less anxiety; it is usually the most effective and efficient way of carrying out the investigation and obtaining the necessary information. However, for this type of investigation it is important to be very organized. The following approach is recommended:

- Identify a single individual at the setting who will be responsible for organizational aspects of the contact investigation and act as liaison, usually a school principal, workplace manager or occupational health manager.
- Protect the confidentiality of the index case (Note investigations should be carried out in compliance with relevant legal/legislative requirements, and that provincial/territorial legislation may permit disclosure in specific circumstances). This may not be easy; there may be considerable pressure for details, and in many situations others may be able to guess the identity of the case. Particularly if the identity of the case is widely known or suspected, enlist the help of setting personnel (e.g. the principal or manager) to plan for successful reintegration of the TB case once noninfectious.
- Visit the site beforehand to get a sense of the environment and organize the screening arrangements; get input from the setting's liaison person to ensure that screening is carried out at a time and in a way that offers the best opportunity for contacts to come to the screening.
- Check that adequate staffing will be available for the screening.
- Include key players at the site, such as occupational health services, human resources or other administrative staff, and union health and safety representatives in planning and communication; they may benefit from information about TB ahead of a general information session as others will likely look to them for advice.
- Prepare a communication plan; identify one individual who will be responsible for media and communications to the general public if necessary; alert public health

communications staff.

- Offer general information/education sessions about TB and the contact follow-up for all parents/employees/residents before the screening sessions; if the number of contacts is relatively small, a separate session specifically for them may be helpful.
- Identify the referral plan for contacts who are TST positive or symptomatic; treat all contacts referred for medical evaluation consistently, ideally by a limited number of health care providers working in coordination with public health. It can be confusing and alarming for a group of contacts if the work-up and treatment advice are inconsistent from person to person.
- Ensure the results of the medical evaluation are provided promptly to the appropriate public health authority.

Contact investigations carried out in work or school settings may be associated with high levels of anxiety. Good organization, communication and transparency (to the extent possible while protecting case confidentiality) are critical aspects of all site-based or expanded contact investigations. Anxiety and misinformation can be minimized by limiting the delay between contacting the site and conducting testing, ensuring that key people at the setting get the same information at the same time, and by holding general education sessions about TB (tuberculosis) and the investigation plan. Communication from all personnel involved in the investigation should be clear, credible and consistent, especially with regard to the actual level of risk involved, interpretation of the TST (tuberculin skin testing) and decisions regarding treatment of LTBI (latent TB infection).

A standard approach to the evaluation of contacts for the presence of active disease and evidence of recent infection:

All identified contacts should be interviewed systematically regarding their exposure to the case, presence of symptoms, risk factors for progression to active TB (tuberculosis) if infected and history of treatment of TB (tuberculosis) or LTBI (latent TB infection). If there are any concerns, rapid evaluation to exclude active TB (tuberculosis) should be carried out. Once active disease has been excluded, contacts should receive a TST (tuberculin skin testing) unless there is a history of prior treatment of TB (tuberculosis) or a documented prior positive TST (tuberculin skin testing) result. The TST (tuberculin skin testing) should be carried out and interpreted regardless of BCG vaccination status. A TST (tuberculin skin testing) of 5 mm or more is considered positive for contacts. Refer also to Chapter 4, Chapter 6 and Chapter 9, Pediatric Tuberculosis.

Note that TB (tuberculosis) assessment of contacts may involve TST (tuberculin skin testing) or an IGRA (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection).

A two-step TST (tuberculin skin testing) is not recommended in the setting of a contact investigation: Skin test conversion can occur as early as 3 weeks after exposure, and it will generally be impossible to differentiate between true TST (tuberculin skin testing) conversion and a boosted reaction in the setting of a contact investigation (refer to Chapter 2 and Chapter 4). This is another reason why only those with significant exposure should be considered contacts.

Window treatment of LTBI for those most susceptible: Contacts who are at very high risk of progression to active disease if infected (children under 5 years; HIV positive or other immunosuppressed individuals) should receive window prophylaxis in the interval between a negative initial TST result and the definitive TST at least 8 weeks after the last day of exposure because of the high risk of progression to active TB if infected. Refer to Chapter 6 and Chapter 9 for additional information.

Evaluation of Contact Investigation:

The results of each contact investigation should be reviewed as they become available, to guide expansion and/or additional follow-up efforts. In addition, program-wide outcomes should be reviewed annually. Along with qualitative assessment of successes and challenges, they are important elements for program evaluation and future planning. Key indicators should include the following:

- initial list of contacts for each infectious TB case, completed within 7 calendar days;
- assessment of close contacts completed and LTBI treatment started, if indicated and not contraindicated or refused, within 28 calendar days;
- proportion of contacts with a diagnosis of LTBI who begin treatment;
- proportion of contacts beginning treatment for LTBI who complete treatment; and
- proportion of contacts completing LTBI (latent TB infection) treatment who show active TB (tuberculosis) disease within 2 years after completion.

Summary Points

Recommended Steps in Contact Investigation and Follow-Up

1. The treating physician and laboratory should report all new or suspected cases of TB (tuberculosis) within 48 hours to the appropriate public health authorities.
2. Each new active case should be interviewed by public health authorities to identify household and other close contacts promptly. TB (tuberculosis) programs should prioritize contacts by the infectiousness of the source case, the extent of the exposure and the risk of progression to active TB (tuberculosis) if infected.

3. Each contact should be interviewed regarding the circumstances and duration of exposure, presence of symptoms, previous history of tuberculosis, TB (tuberculosis) exposure and prior TST (tuberculin skin testing).
4. Public health authorities and the treating physician should collaborate to ensure that contacts with no previous history of TB (tuberculosis) or documented positive tests receive a TST (tuberculin skin testing) and symptom assessment.
5. In the context of contact investigation, a positive TST (tuberculin skin testing) result is 5 mm or greater on initial or repeat testing, or an increase of at least 6 mm from a previous TST (tuberculin skin testing) of 5-9 mm. A history of BCG vaccination does not alter the interpretation of the skin test results for contacts. TST (tuberculin skin testing) should be repeated at least 8 weeks after the last exposure for all high-priority contacts who had an initial negative test. Refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, for guidance.
6. A medical evaluation to rule out active TB should be performed for all contacts who have symptoms compatible with TB; a positive TST result, whether before exposure or at initial or repeat testing; and (regardless of the results of the initial TST) all children under age 5, as well as contacts who are HIV seropositive or severely immunocompromised, according to the recommendations in Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance, Chapter 9, Pediatric Tuberculosis, and Chapter 10, Tuberculosis and Human Immunodeficiency Virus. This should include chest radiography, plus sputum collection as indicated.
7. Once active TB (tuberculosis) has been ruled out, treatment of LTBI (latent TB infection) should be offered according to the recommendations in Chapter 6, Treatment of Latent Tuberculosis Infection, Chapter 9, Pediatric Tuberculosis, and Chapter 10, Tuberculosis and Human Immunodeficiency Virus.
8. Public health authorities should determine the need to extend the contact investigation on the basis of the contagiousness of the index case, the results of the investigation of high-priority contacts and the nature of the exposure of additional contacts.
9. Extended contact investigations should be carried out in a systematic and organized manner; public health/TB control should coordinate these investigations.

The results of the contact investigation should be evaluated by the TB (tuberculosis) management program.

Contact Investigations in Special Settings

Homeless and Underhoused People and Those with Drug Addictions

Contact tracing for cases who are homeless, heavy users of illicit drugs and other highly marginalized individuals is very challenging and resource intensive. It is easy to become frustrated and overwhelmed. These challenges can be made more manageable and successful by recognizing that such cases are not "business as usual," keeping priorities clearly in mind, training staff and allocating adequate resources.

Many homeless TB (tuberculosis) cases may suffer from alcoholism, drug addiction or mental illness, which complicates the management of their TB (tuberculosis) [46].They may have poor access to health services and multiple medical comorbidities, resulting in delayed TB (tuberculosis) diagnosis, worsening of the disease, prolonged periods of infectiousness and thus large numbers of contacts who need to be assessed. High baseline prevalence rates of TST (tuberculin skin testing) positivity also mean that a large number of contacts will require further assessment and possible treatment of LTBI (latent TB infection) [47-51].

Information that is easily collected from other individuals with TB can prove very difficult to gather from homeless individuals. They may not know the names of friends/associates or only a street name, or where to find them; recall may be severely limited by addiction or mental illness and sometimes by mistrust of authorities. Drug users may be very reluctant to implicate those they use drugs with for fear of legal prosecution. It may be most productive to try to identify any particularly close friends by name and otherwise to focus on setting-based follow-up. Cases may be highly mobile, with many locations exposed. Shelters may have bed logs, which can be used to identify room-mates; in large shared rooms, prioritize those who spent the most nights with the case and slept closest. Bear in mind that ventilation patterns, including fans, can affect transmission. Rooming houses (also known as single-room occupancy hotels) are often very cramped and poorly ventilated. Homeless shelters may be closed during the day; ask about meals, drop-in centres providing services for the homeless (day-use shelters), libraries, bars, parks, etc. Shelter staff or social service agency workers may be able to identify daily patterns, or friends, and family of the case. If there are gaps in the available history during the infectious period, it may also be worthwhile to check for recent hospitalizations or detainment in a correctional facility. It will be extremely helpful to involve staffs who are familiar with the local homeless sector in contact follow-up.

Homeless contacts are often difficult to locate, and have significant challenges following through on screening, medical evaluation, and preventive treatment for LTBIFootnote 52.Non-judgmental and supportive TB staff, and judicious use of incentives and enablers may help increase participation rates. Active participation and encouragement from trusted staff at the shelter or day-program (e.g. a drop-in centre or soup kitchen) during screening clinics is especially helpful. Persistence and flexibility are critical. Someone who is not co-operative one

day may be willing to participate another time; interventions which can be carried out on-site or in a single session generally have more success than those involving extra visits or travel (e.g. sputum collection on site, portable chest x-ray , IGRA vs TST planting and reading)Footnote 53-55. The primary focus should generally be on early detection of secondary cases; LTBI should be assessed and treated only if individuals meet the medical and social criteria for treatment of LTBI.

Refer also to Chapter 15, Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings, for additional discussion on the prevention of TB (tuberculosis) in homeless shelters.

Correctional Facilities

Residents of correctional facilities often have a higher prevalence of TB infection and disease; large outbreaks of TB have occurred in prisons in the United States, Russia and elsewhereFootnote 56-58. Older facilities in particular are often overcrowded and poorly ventilated, increasing the risk of spread. Some residents have comorbid medical conditions, such as HIV infection, that increase progression of TB infection to active disease; mental illness and mistrust of authorities can make clinical assessment difficult.

When an infectious case of TB (tuberculosis) is identified in a correctional facility, contacts can include fellow inmates and employees at the facility, transportation staff, visitors, courthouses, and family or community members exposed before the case was incarcerated. Multiple corrections facilities may be involved, as both provincial and federal inmates are often moved between sites, and both case and contacts may have had multiple incarcerations during the infectious period [45].However, where inmates are given a TST (tuberculin skin testing) on admission and/or annually, these results may be available as a baseline for contact follow-up. To assist in the identification of contacts, correctional facilities should track inmate transfers, releases and movement within a facility and within the system.

Levels of anxiety may be very high among corrections staff during a TB investigation and have sometimes resulted in facility closures or work stoppages. Ongoing relationships with local public health/TB control staff can help mitigate this. It is extremely helpful to include senior corrections staff, particularly chiefs/directors of health care, and union health and safety representatives early in planning and communication; if multiple facilities are involved, provincial/territorial or senior federal corrections officials should be included. If suspect cases are identified during contact follow-up, they should be removed from the general

ranges/shared cells pending diagnostic confirmation. Suspect and confirmed infectious cases should be kept in airborne isolation rooms if available within correctional facilities or transferred to hospital.

Correctional Service Canada has developed guidelines for TB (tuberculosis) prevention and control in institutions that house inmates sentenced to 2 years or longer. Contact publichealth@csc-scc.gc.ca to obtain a copy.

Health Care Institutions

Hospital TB (tuberculosis) contact follow-up benefits from close coordination and collaboration between public health/TB (tuberculosis) control staff and hospital infection control/occupational health staff. While almost every type of health care institution has been implicated in nosocomial transmission, there is very little by way of published hospital contact follow-up studies to guide thoughtful contact follow-up [59-61]. Unless the contact investigation is conducted in an organized, systematic fashion, with the basic principles of transmission in mind, it may result in hundreds of "contacts" with limited or unknowable exposure and often dismal participation and follow-up completion rates. It is often very useful to measure air exchange rates in specific hospital exposure locations, in order to help prioritize contact follow-up. It is also important to confirm whether there were any unprotected aerosolizing procedures, such as intubation, carried out on the infectious case (i.e. when staff did not use N95 masks). Some types of patients are extremely vulnerable (e.g. transplant patients) and even short exposures may be relevant (refer to Chapter 6). Visitors to the case and to room-mates may have significant exposure. Hospital infection control and occupational health departments often take advantage of TB (tuberculosis) exposures to get staff TST (tuberculin skin testing) documentation up to date, but within this larger group of staff being tested it is important to distinguish those who have the most actual exposure to the infectious case - particularly if there are conversions detected. Pooling the results of contact follow-up within and outside of the hospital can help to focus the investigation and determine the need, if any, for expansion. Notification of contacts may come from the hospital and/or public health authority, and testing can be done by the hospital, public health authority or personal physicians, but the plan should be agreed on by all parties to avoid confusion and gaps.

Individuals who are immunosuppressed are at much higher risk of TB disease after infection with TB; thus, TB exposures in specialty services or clinics may pose an especially high risk. For example, among dialysis patients in British Columbia, the annual rate of TB was 25 times higher than among age-matched population controlsFootnote 62.Nosocomial transmission of TB to people with HIV is well documented in both inpatient and outpatient settingsFootnote 63 Footnote 64. Refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, Chapter 6,

Treatment of Latent Tuberculosis Infection, and Chapter 10, Tuberculosis and Human Immunodeficiency Virus, for additional information on assessment and management of these contacts. Also, refer to Chapter 15, Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings.

Long-Term Care

Many of the same issues for hospitals apply to TB (tuberculosis) exposures in long-term care facilities. For residents who are contacts of an infectious case of TB (tuberculosis), the most critical follow-up is assessment for active disease through careful symptom evaluation, chest radiography and sputum testing. Diagnosis of active TB (tuberculosis) in the elderly can be difficult, and expert clinical consultation may be necessary. Gastric washings may be easier to obtain than spontaneous or induced sputum in demented or very elderly residents. TST (tuberculin skin testing) is not recommended as a primary contact assessment tool for residents over 65 years [65].Interpretation of TST (tuberculin skin testing) results in the elderly is often complicated by both immune suppression and the potential for boosting related to remote TB (tuberculosis) exposure or BCG [66-69]. As well, for many elderly contacts the risks of LTBI (latent TB infection) treatment outweigh the potential benefits. However, contacts among staff and visitors ≤65 years old should receive a TST (tuberculin skin testing). In the absence of secondary cases, their results are likely to be a more reliable indicator of transmission in the facility.

Remote Communities

Contact investigation in a remote community may be especially challenging. Access to diagnostic tests, staffing, TB expertise and resources may be difficult. In remote First Nations or Inuit communities there may also be significant language and cultural barriers to successful contact tracing. Nowhere are organization, education, communication and a collaborative, nonjudgmental approach more important. The provincial/territorial TB program, the local public health/TB control program, Health Canada's First Nations and Inuit Health Branch if it is involved in the delivery or funding of health services in the community, local health care providers and the community should work closely together to identify secondary cases and contacts quickly, and then to see that they are properly managed over the duration of medical investigation and treatment. A mobile or portable radiography unit may need to be brought to the community; liberal use of sputum screening may also be useful in coordination with the public health laboratory. Otherwise, a special effort should be made to facilitate the timely transport of people with suspected TB to a larger medical centre

for investigation. Directly observed preventive therapy is a treatment option for newly infected contacts in First Nations and Inuit communitiesFootnote 70.Also, refer to Chapter 14, Tuberculosis Prevention and Care in First Nations, Inuit and Métis Peoples.

Contacts During Air Travel and Other Public Transport

The World Health Organization (WHO (World Health Organization)) publishes guidelines [71] outlining the procedures for notifying certain contacts of people with infectious TB (tuberculosis) who have travelled on an international flight with a total duration of ≥8 hours within the previous 3 months. The 8 hour duration is based on epidemiologic studies reviewed in the WHO guidelines. In Canada, reports of people with TB (tuberculosis) who report a history of air travel while infectious should be made to the Public Health Agency of Canada (PHAC (Public Health Agency of Canada)) through the provincial/territorial TB (tuberculosis) program (even if the flight occurred more than 3 months ago, as passenger records are usually still available). The reporting form and detailed guidelines can be found at Public Health Agency of Canada, Reporting Forms website. The report to PHAC should be made as soon as possible (even if culture and antibiotic sensitivity results are still pending), as this speeds up the process of risk assessment and securing the necessary passenger information from the airline. However, a systematic review of 12 studies suggests that the value of actively screening airplane passengers is limited [72].

The few published reports of contact tracing after exposure to TB (tuberculosis) on buses and trains indicate that transmission is sometimes possible on repeated daily exposure, such as on school buses or on long-distance trips [73].Such events appear to be rare, involving highly infectious cases and specific environmental circumstances (e.g. daily travel on a crowded long-duration school bus route in winter). There is no evidence to support contact tracing related to local public transportation, particularly given the logistic hurdles and considerable inefficiency of contact tracing in these circumstances [73].

Possible Contact with Infectious TB (tuberculosis) Cases During Residence or Travel in a Country with High TB (tuberculosis) Incidence

Refer to Chapter 13, Tuberculosis Surveillance and Screening in Selected High-Risk Populations.

Management of a TB (tuberculosis) Outbreak

TB outbreaks generally last for several years; response and control are major undertakings [74-76]. In addition, outbreaks are more likely to occur in already challenging settings, such as homeless, impoverished, or other marginalized populations, isolated Inuit or First Nations

communities, etc [44] [54]

Definition

The definition of an outbreak of any disease is the occurrence of more cases in a given population than expected in a given time. Spatial or temporal associations may suggest ongoing transmission and an outbreak. TB (tuberculosis) outbreaks may be identified only retrospectively, after cases have been found to be linked epidemiologically or by genetic analysis. Any such clustering within the last 2 years should suggest a possible outbreak and prompt further investigation.

The following working definition of outbreak for planning investigations is based on that proposed by the U.S. Centers for Disease Control and Prevention: [22]

- During and because of a contact investigation, two or more of the identified contacts are diagnosed as secondary cases of active TB; or
- Any two or more cases occurring within 1 year of each other are discovered to be linked, but the linkage is recognized outside of a contact investigation. For example, two patients who received a diagnosis of TB (tuberculosis) independently, outside of a contact investigation, are found to work in the same office, yet they were not previously identified as contacts of each other. A more extreme example is when a second generation of transmission has already occurred at the time an index case is diagnosed - i.e. secondary cases have already generated their own secondary cases. The linkage between cases should be confirmed by genotyping results if cultures are available.

This definition emphasizes the pace of secondary cases occurring and the ability of the TB (tuberculosis) program to keep up with multiple contact investigations. In practice, the ability of the local TB (tuberculosis) program to manage a growing cluster of TB (tuberculosis) cases and the concurrent contact investigations in a timely way, within its usual operations, is also a key factor in determining whether or not to consider the situation an outbreak for response purposes. Most situations that have been recognized as TB (tuberculosis) outbreaks involve chains of many more than two secondary cases, or one previously unrecognized link to a secondary case, and extend over several years. The above definition is an operational one intended to help identify and contain rapidly evolving clusters. Note that a slower cluster of linked cases that spans several years may still require heightened TB (tuberculosis) program response for an identifiable population group yet not be an "outbreak" by the above definition.

Goals

The goals of the investigation and management of an outbreak of TB (tuberculosis) are as follows:

- to promptly identify the source case or cases, so that the risk of ongoing transmission of infection is rapidly reduced by isolation and initiation of appropriate treatment
- to rapidly identify new cases of active TB (tuberculosis) within the at-risk population, and initiate airborne isolation and treatment
- to identify people with recently acquired LTBI (latent TB infection), so that preventive therapy can be given before active disease develops.

Managing an Outbreak

Organization and resources

Given the scale and duration of most TB (tuberculosis) outbreaks, it is important that there be adequate staffing and resources for investigation and management from the onset of the response efforts. Assistance from outside the TB (tuberculosis) program may be necessary. Advice from experienced colleagues who have managed TB (tuberculosis) outbreaks elsewhere can be invaluable.

The following components are recommended in any TB (tuberculosis) outbreak response:

- an identified outbreak manager, appointed for the duration, with overall responsibility for management and coordination of the outbreak response;
- public health/TB control staff to register and case-manage patients with TB, define infectiousness, coordinate the investigation and provide consultation and communication with those in the field;
- sufficient field staff to carry out the contact investigation and follow-up; for outbreaks dispersed across remote communities, mobile specialized teams may be an effective strategy to support local staff;
- information technology (IT)/database and epidemiologic support;
- consistent, coordinated clinical and diagnostic supports with expertise in TB; prompt, local access to chest radiography of adequate quality, identified medical consultants with expertise in TB to review chest radiology, evaluate patients for TB, hospitalize if necessary, and manage suspected cases and contacts in a consistent manner, without delay; for remote communities telemedicine links (including review of digital radiology) can be extremely effective, hospital facilities that can offer airborne isolation rooms, diagnostic examinations and treatment without delay, links to public health laboratories for specialized supports (arrangements to handle larger numbers of specimens,

fingerprinting, etc.), rapid and safe transportation of specimens and, if necessary, patients;
- sufficient case-management and DOT staff to provide supervision of the complete course of drug treatment for all active cases - at least 1 year's additional staffing after the outbreak is over may be required;
- communications personnel to provide regular updates to the media and community on the status of the investigation;
- staff and resources to carry out the evaluation.

Roles and responsibilities

It is crucial, from the onset of the investigation, that the roles of all those involved in the investigation and management are clearly defined. Establishing an outbreak coordinating group, including the key individuals from public health/TB (tuberculosis) control, clinical expert care, hospitals, laboratory, the affected community and communications, can be very helpful. Collaboration and regular feedback among all levels of health care are important. There should be clear agreement to be followed in the investigation and the management of suspected cases and contacts, and written protocols.

Communication with health care providers

Local health care providers, particularly those who are most likely to first see new cases of TB (tuberculosis) in the outbreak population (emergency room, primary care in the outbreak neighbourhood, etc.) are key partners. Presentation at medical rounds, written notification about the outbreak and other ongoing communication will help to raise the index of clinical suspicion for TB (tuberculosis), provide up-to-date information about TB (tuberculosis) diagnosis and management, and help decrease barriers to care, including early hospitalization for suspected infectious cases when necessary.

Staff training

Given the scale of TB outbreaks and response, many staff involved may not be experienced in TB work; including training and education/clinical rounds at all the organizations involved in the response plan can be helpful.

Prompt isolation and treatment of cases of active disease

An outbreak should markedly raise the index of clinical suspicion for TB (tuberculosis) when anyone in the affected community presents with compatible symptoms, particularly for respiratory (i.e. infectious) TB (tuberculosis). All suspected infectious cases should be

promptly isolated - in hospital if necessary - and investigated to confirm the diagnosis and the degree of infectiousness. Suspect cases should not return to congregate settings until infectious TB (tuberculosis) has been ruled out.

Case-finding, identification of source case, and contact investigation

In outbreaks among homeless and other marginalized populations, outreach street nursing, primary care clinics on site at shelters or other homeless services, and other low-threshold types of care are often critical for early diagnosis [44, 75, 75, 76]. Shelter staff may be the first to identify an ill resident; training about TB and infection control precautions, basic symptom screening on admission, and mechanisms to rapidly isolate and refer suspect TB cases for medical evaluation should be implemented.

If not apparent, the source case or cases should be identified through aggressive investigation of all symptomatic individuals in the at-risk community. Once the initial investigation is under way, a review of the history of TB (tuberculosis) in the community is important. Review of "old cases" by provincial/territorial and local public health/TB (tuberculosis) programs may identify previously inadequately treated cases. In some circumstances it may be helpful to locate and reassess previously identified high-risk contacts who were lost to follow-up or did not take or complete treatment for LTBI (latent TB infection).

In small communities or in closed settings it may be more efficient to screen the entire community or those in the facility at baseline, especially as it may be difficult to determine the exact level of contact in a small, close-knit community. In some settings, especially if members are very mobile, offering on-site active case-finding (sputum and/or chest radiography as well as symptom screening) on an ongoing basis over an extended period of time may be the only way to ensure that most contacts are identified and screened [53-55, 75-77]. Many remote communities have members who travel back and forth frequently to other communities; tracking these individuals is particularly difficult, yet they can be a conduit to spread the outbreak to additional communities. Coordination and shared follow-up arrangements with TB programs in these other communities may be very helpful in the assessment and management of mobile contacts and cases.

In populations in which treatment of LTBI (latent TB infection) is not realistic as a major outbreak control strategy, the primary emphasis should be on early detection and treatment-to-cure of active cases, rather than extensive efforts to do skin testing. Examples include elderly residents (over 65 years) in long-term care facilities and some homeless populations (e.g. older alcoholics). Also, refer to Chapter 15.

A heightened index of clinical suspicion and perhaps case finding efforts should be maintained for several years after the outbreak subsides, as there is usually a pool of recently infected people remaining in the community. It may be possible to follow infected contacts who refuse or are not eligible for treatment of LTBI (latent TB infection) in order to detect early TB (tuberculosis) disease (e.g. periodic clinical assessment for 2 years after exposure).

Data management and epidemiologic support

Contact investigation and management in a TB (tuberculosis) outbreak is very data-heavy. Tracking hundreds of contacts, often through multiple sites and assessments, demands a good database and IT support. Rapid, thoughtful evaluation of the aggregate results as they become available requires a dedicated epidemiologist.

Identify fundamental causes

TB (tuberculosis) outbreaks mainly take place in settings where rapid transmission is possible - inadequate housing (overcrowding, inadequate ventilation) and prolonged infectiousness often related to limited health care access. A high prevalence of vulnerability factors among contacts accelerates the development of secondary cases: the presence of many young children, diabetes and other causes of immunosuppression, smoking, malnutrition, etc. In facility-based outbreaks (homeless shelters, hospitals, jails) a systematic assessment of conditions and practices, including ventilation, may identify areas for intervention (also, refer to Chapter 15). Individual cases can be treated and cured, but it is very difficult to contain outbreaks or reduce endemically high rates of TB (tuberculosis) without addressing the fundamental causes. These aspects, too, should be recognized, and when possible addressed in the outbreak response.

Community outreach and education

TB (tuberculosis) outbreaks can be anxiety-provoking and stigmatizing. Often they take place in a context of limited or inaccurate information about TB (tuberculosis) and sometimes quite negative cultural/historical associations. All these can prolong the situation through delayed diagnosis if individuals either do not recognize the significance of their symptoms or are afraid to receive a diagnosis of TB (tuberculosis). It is crucial to provide information about TB (tuberculosis) and the outbreak response to the affected community or setting as early as possible in the investigation of the outbreak, with regular updates for them and for the general local population. The information should be in a style and format that is accessible and takes into account the cultural and practical setting of those affected. Standard materials

may need to be adapted, ideally with input from community members. Peer outreach may be very useful, particularly for hard-to-reach individuals. This will help reduce the level of anxiety and will likely lead to greater cooperation and adherence to recommendations.

Evaluate the process and outcome of the outbreak investigation

Ongoing evaluation and a formal evaluation at the end of the outbreak, including both the process and outcome of the outbreak investigation, are crucial. DNA genotyping of isolates may be useful in identifying the presence of an outbreak, mapping its extent and evaluating the results of the outbreak investigation and control. Identification of key contributing factors, often social determinants of health, may point to future non-TB (tuberculosis)-specific interventions.

Chapter 15 - Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings

PDF Document, 751 KB - 49 pages

Canadian Tuberculosis Standards 7th Edition

- Table of Contents
- Preface
- Acknowledgements
- Chapter 1. Epidemiology of Tuberculosis in Canada
- Chapter 2. Pathogenesis and Transmission of Tuberculosis
- Chapter 3. Diagnosis of Active Tuberculosis and Drug Resistance
- Chapter 4. Diagnosis of Latent Tuberculosis Infection
- Chapter 5. Treatment of Tuberculosis Disease
- Chapter 6. Treatment of Latent Tuberculosis Infection
- Chapter 7. Nonrespiratory Tuberculosis
- Chapter 8. Drug-resistant Tuberculosis
- Chapter 9. Pediatric Tuberculosis
- Chapter 10. Tuberculosis and Human Immunodeficiency Virus
- Chapter 11. Nontuberculous Mycobacteria
- Chapter 12. Contact Follow-up and Outbreak Management in Tuberculosis Control
- Chapter 13. Tuberculosis Surveillance and Screening in Selected High-risk Populations
- Chapter 14. Tuberculosis Prevention and Care in First Nations, Inuit and Métis Peoples
- Chapter 15. Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings
- Chapter 16. Bacille Calmette-Guérin (BCG) Vaccination in Canada

Appendices

- Appendix A. Glossary
- Appendix B. Canadian Tuberculosis Surveillance Systems
- Appendix C. Tuberculosis Training and Education Resources
- Appendix D. Tuberculosis and Mycobacteriology Laboratory Standards: Services and Policies
- Appendix E. Contributors

Chapter 15 - Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings

Toju Ogunremi, BSc, MSc
Dick Menzies MD, MSc
John Embil, MD, FCAP

Table of Contents

1. Key Messages/Points
2. Major Recommendations
3. Introduction and General Principles
    - 3.1 Determinants of Transmission of *Mycobacterium tuberculosis*
    - 3.2 Respiratory (Pulmonary or Laryngeal) TB (tuberculosis) Disease
    - 3.3 Number of Patients with Respiratory TB (tuberculosis) Disease
    - 3.4 HIV (human immunodeficiency virus) Infection
    - 3.5 Delayed Diagnosis
    - 3.6 Incorrect, Ineffective or No Therapy
    - 3.7 Inadequate Ventilation
    - 3.8 Duration of Exposure and Proximity to Infectious Patient
    - 3.9 Overcrowding
4. Risk Classification
    - 4.1 Health Care Settings
    - 4.2 HCW (healthcare workers) Activities
    - 4.3 Laboratory Personnel Handling *M. tuberculosis*
5. Prevention and Control of Transmission of *M. Tuberculosis*
    - 5.1 Administrative Controls within Hospitals
    - 5.2 Tuberculosis Management Program
    - 5.3 Risk Assessment
    - 5.4 Education of HCW (healthcare workers)s

Key Messages/Points

- The scope of this chapter includes hospitals; other health care settings; and residential and community care settings.
- Health care organizations and individual health care workers (HCW (healthcare workers) (health care workers)s) have a shared responsibility to apply effective tuberculosis infection prevention and control measures.
- The risk of health care associated transmission of *M. tuberculosis* varies with the type of setting, HCW (healthcare workers) occupational group, patient care activity, patient/resident/client population and the effectiveness of tuberculosis (TB (tuberculosis)) infection prevention and control measures.
- The most important contributors to health care associated transmission of *M. tuberculosis* are patients with unrecognized, respiratory TB (tuberculosis) disease. Hence, the most important element of any TB (tuberculosis) management program is rapid diagnosis, isolation and start of effective therapy for these patients.
- Remote and isolated health care settings in which at-risk populations are cared for should have access to resources to facilitate implementation of essential administrative, environmental and personal protective controls.

Major Recommendations

- All health care settings should have a TB (tuberculosis) management or infection prevention and control program supported at the highest administrative level. This involves a hierarchical approach to infection prevention and control measures categorized as administrative, environmental and personal protection controls.
- Airborne precautions should be initiated immediately for everyone with suspected or confirmed respiratory TB (tuberculosis) disease admitted to a hospital. The criteria for discontinuation of airborne precautions include the following: establishment of an alternative diagnosis, clinical improvement, adherence to effective therapy,

sputum smear and/or culture conversion, and drug-susceptibility tests that indicate fully sensitive organisms or low clinical suspicion of drug resistance.

- U.S. National Institute for Occupational Safety and Health (NIOSH (National Institute for Occupational Safety and Health) (National Institute for Occupational Safety and Health))-certified respirators (N95 or higher filter class) should be used by HCW (healthcare workers)s providing care for or transporting patients with suspected or confirmed respiratory TB (tuberculosis) disease.
- Masks should be used by patients/people with suspected or confirmed respiratory TB (tuberculosis) disease when outside an airborne infection isolation room.
- Baseline tuberculin skin testing (TST (tuberculin skin testing)) is recommended for all HCW (healthcare workers)s in health care and community care settings. Recommendations for periodic and serial (repeated) TST (tuberculin skin testing) for HCW (healthcare workers)s vary with the setting. Interferon-gamma release assays are not recommended for serial testing.

Introduction and General Principles

While the incidence of tuberculosis (TB (tuberculosis)) in Canada is generally low, exposure to people with unsuspected active respiratory TB (tuberculosis) disease followed by transmission of *M. tuberculosis* does occur in health care settings [1] [2]. A survey of TB (tuberculosis) control services in all Canadian provinces and territories in 2008 reported a total number of 1,562 cases of active TB (tuberculosis) disease and 11,935 people treated for latent TB (tuberculosis) infection (LTBI (latent TB infection)) [3]. Approximately 50% of people with active TB (tuberculosis) disease in this survey were admitted to hospital for an average of 21 days. Although the overall number of people admitted to Canadian health care facilities with active TB (tuberculosis) disease is low, both health care and community settings (e.g. homeless shelters and drop-in centres) serving at-risk populations continue to pose a hazard for the transmission of *M. tuberculosis* [4] [6]. Populations at risk of active TB (tuberculosis) disease include people with a history of active TB (tuberculosis) disease; staff and residents of homeless shelters; urban poor; staff and inmates of correctional facilities, including previously incarcerated people; injection drug users; people born in Canada prior to 1966; Aboriginal Canadians; people infected with human immunodeficiency virus (HIV (human immunodeficiency virus)); those born or previously residing in countries with a high TB (tuberculosis) incidence (in Asia, Eastern Europe, Africa and Latin America); and HCW (healthcare workers)s serving these at-risk groups [7] [10].

Literature reviews show that the incidence of LTBI (latent TB infection) among HCW (healthcare workers)s increases with certain occupational risk factors, including number of years working in health care settings where patients with active respiratory TB (tuberculosis) are cared for, providing direct care to those with respiratory TB (tuberculosis) disease, working in emergency departments or medical wards, providing services for patients infected with HIV (human immunodeficiency virus), and participating in aerosol-generating medical procedures (e.g. sputum induction and bronchoscopy) on individuals with TB (tuberculosis) [5] [11] [12].

In hospitals, clinics, community care centres and correctional facilities, where people congregate and share indoor air (in the same room or via the building ventilation system), the risk of *M. tuberculosis* transmission can be increased if ventilation and other infection prevention and control measures are inadequate. In addition, exposure to people with active, undiagnosed and untreated respiratory TB (tuberculosis) disease has resulted in high rates of positive TST (tuberculin skin testing) results in HCW (healthcare workers)s [1] [2] [5] [13]. Reported TB (tuberculosis) outbreaks within health care facilities are often due to failure to implement appropriate TB (tuberculosis) infection prevention and control measures [4]. These observations have heightened concerns and resulted in the formulation of recommendations for the prevention of health care associated transmission of *M. tuberculosis* to HCW

(healthcare workers)s, patients and visitors [7] [14] [15]. A review of the literature suggests that implementation of a full hierarchy of infection prevention and control measures in many hospitals, as recommended in published guidelines, has led to successful reduction in *M. tuberculosis* transmission [5] and is therefore considered integral to preventing transmission in hospitals, other health care settings, and residential and community care facilities.

This chapter reviews factors that determine or affect transmission of *M. tuberculosis* within hospitals, other health care settings, and residential and community care settings while focusing on measures to prevent transmission. The term HCW (healthcare workers)s refers to individuals in health care settings who provide health care or support services, such as physicians, nurses, nurse practitioners, paramedics, emergency first responders, respiratory therapists, unregulated health care providers, clinical instructors, students, volunteers, and housekeeping, dietary and maintenance staff [16].

Recommendations are based, as much as possible, on published evidence to date. However, the evidence applicable to infection prevention and control of *M. tuberculosis* that is based on randomized controlled trials, generally considered the strongest level of evidence, is limited. This type of study design is generally not feasible or practical when analyzing risk factors or situations involving natural exposure (e.g. TB (tuberculosis) outbreaks). As a result, the majority of the available evidence comes from observational studies, such as cohort or case-control studies, and from qualitative analyses of outbreaks. This chapter cites the evidence base from these primary studies, as well as from several published literature reviews [5] [9] [17] and from a systematic review that includes recommendations from the US Centers for Disease Control and Prevention (CDC (Centers for Disease Control and Prevention)) [7]. Recommendations are itemized in boxes, tables or algorithms with the strength of the recommendation and the quality of its evidence indicated (refer to Preface for explanation of rating). Where detailed information is beyond the scope of this chapter or further references are of interest, refer to the relevant chapter(s) in this book.

Determinants of Transmission of Mycobacterium tuberculosis

Aerosolization of infectious *M. tuberculosis* bacteria occurs when individuals with respiratory TB (tuberculosis) disease cough, sneeze, sing, play wind instruments or speak. Cough-inducing procedures (e.g. bronchoscopy, sputum induction) as well as some laboratory and autopsy procedures can also cause aerosolization of mycobacteria. Once infectious *M. tuberculosis* bacteria are aerosolized, they are carried throughout a room or building by air currents and can be inhaled by another individual, with the possibility of resulting in TB (tuberculosis) infection. Although the risk of transmitting *M. tuberculosis* is highly variable, the presence of certain factors (refer to section Factors associated with increased risk of transmission of *M. tuberculosis bellow*) predicts an increased transmission risk. In general, the more of these factors present, the greater the risk of *M. tuberculosis* transmission. For further discussion on determinants of *M. tuberculosis* transmission, refer to Chapter 2, Transmission and Pathogenesis of Tuberculosis.

Factors Associated with Increased Risk of Transmission of *M. tuberculosis*

- **Patient factors**
  - Respiratory (pulmonary or laryngeal) disease [A]
  - Number of Patients with Respiratory TB (tuberculosis) Disease [A]
  - Respiratory secretions that are acid-fast bacteria (AFB (acid-fast bacteria)) smear positive
  - Presence of cough
  - HIV (human immunodeficiency virus) infection [A]
  - Atypical manifestations of disease
- **Diagnostic/laboratory risk factors**

- Cough-inducing procedures, e.g. sputum induction, bronchoscopy or administration of aerosolized therapies
- Delayed diagnosis [A]
- Autopsy and preparation of pathology specimens
- Improper handling of laboratory specimens containing *M. tuberculosis*

- **Treatment factors**
  - Incorrect, ineffective or no therapy [A]
  - Delayed treatment
- **Environmental factors**
  - Inadequate ventilation to remove airborne infectious *M. tuberculosis* [A]
  - Inadequate TB (tuberculosis) infection prevention and control measures for containment of *M. tuberculosis*
  - Duration of exposure and proximity to infectious patient [A]
  - Overcrowding [A]
  - Absence of sunlight
  - High humidity

A
These factors are discussed below.

Respiratory (Pulmonary or Laryngeal) TB (tuberculosis) Disease

People with laryngeal TB (tuberculosis) disease show the highest infectivity of all forms of TB (tuberculosis). While most people with nonrespiratory TB (tuberculosis) alone are not infectious, it is important to exclude concomitant respiratory involvement, which occurs in a significant proportion of those with nonrespiratory TB (tuberculosis) [18]. Pleural TB (tuberculosis) disease in the absence of concomitant respiratory involvement is not considered infectious, refer to Chapter 2, Transmission and Pathogenesis of Tuberculosis.

Number of Patients with Respiratory TB (tuberculosis) Disease

It is generally understood that the number of hospitalized patients with respiratory TB (tuberculosis) disease, particularly before diagnosis and treatment, is an important determinant of institutional transmission risk. Results from one study involving 17 acute-care hospitals in Canada showed that with effective implementation of infection prevention and control measures the number of patients might not be the best indicator of transmission risk. In this study, institutional risk of *M. tuberculosis* transmission was found to be better correlated with delayed diagnosis and treatment [19] .Thus, prompt diagnosis followed by early isolation and appropriate treatment has a mitigating effect on this risk factor [5].

HIV Infection

There is no clear evidence that people infected with *M. tuberculosis* are more infectious if they are coinfected with HIV (human immunodeficiency virus). However, there will often be rapid development of active TB (tuberculosis) disease, [20] and HIV (human immunodeficiency virus)-related TB (tuberculosis) disease will often have atypical clinical manifestations, leading to delayed diagnosis. The increased risk of *M. tuberculosis* transmission by this population is related to the potential for delayed isolation if the index of suspicion for respiratory TB (tuberculosis) disease is low. Also, refer to Chapter 10, Tuberculosis and Human Immunodeficiency Virus.

Delayed Diagnosis

Refer to section "Identification of patients with active respiratory TB (tuberculosis) within hospitals" in this chapter.

Incorrect, Ineffective or No Therapy

The administration of incorrect or ineffective therapy or no therapy at all contributes to the risk of transmission. Refer to Chapter 5, Treatment of Tuberculosis Disease.

Inadequate Ventilation

The exchange of indoor air with outdoor air reduces the risk of infection by diluting the concentration of viable airborne *M. tuberculosis* bacteria present [1]. Theoretically, the risk of transmission should decrease exponentially with increasing fresh-air ventilation.

Duration of Exposure and Proximity to Infectious Patient

The risk of TB (tuberculosis) infection varies with duration of exposure, form of tuberculous disease and type of patient care activity. In one study, an hour of exposure during bronchoscopy on a patient with unrecognized smear-positive disease resulted in a 25% risk of infection [12] and in another study exposure to a patient with laryngeal TB (tuberculosis) resulted in a 1.7% risk of infection per hour [21]. Even when the relative risk of infection is low, repeated exposure can lead to a higher cumulative risk. For example, if a HCW (healthcare workers) is exposed for 1 hour each week, the cumulative risk can approach 100% after 10 years of repeated exposure.

Overcrowding

Overcrowding contributes to transmission in settings like homeless shelters and correctional facilities. The relative importance of select factors (such as overcrowding, duration of exposure and proximity to infectious people in a confined space) to *M. tuberculosis* transmission has not been quantitatively described in the literature, but some reports suggests that their impact is highly variable [22].

Risk Classification

Health Care Settings

The risk of health care associated transmission of *M. tuberculosis* to HCW (healthcare workers)s, patients (or residents) and visitors varies with the type of setting, occupational group, effectiveness of TB (tuberculosis) infection prevention and control measures, and patient/resident population [7]. A review of the community profile of TB (tuberculosis) disease, as well as the risk category of the health care facility and unit, can be used to conduct facility and/or unit risk assessments. This provides a framework for institutions to predict whether their workers are at increased risk of TB (tuberculosis) exposure so that the necessary infection prevention and control strategies can be implemented.

An approach to classifying risk of *M. tuberculosis* transmission in health care settings is described in Table 1. The risk categories presented have been modified from previous classifications [4] [23] and are based upon review of the available literature [7]. While the number of people with respiratory TB (tuberculosis) disease in a facility during a year is considered a key determinant of transmission risk, the likelihood of exposure to any one patient or resident can vary considerably among facilities. To account for this, the classification below is based on the number of active patient or resident beds and number of cases of respiratory TB (tuberculosis) disease diagnosed in the facility in a typical year.

Table 1. Risk classification for health care settings

Risk category	Facility size	Number of active TB (tuberculosis) cases present annually
Low	Hospitals: ≥200 beds	<6
	Hospitals: <200 beds	<3
	Long-term care institutions including homes for the aged, nursing homes, chronic care facilities, hospices, retirement homes, designated assisted living centres and any other collective living centre	<3
Not considered low	Hospitals: ≥200 beds	≥6
	Hospitals: <200 beds	≥3
	Long-term care institutions (as listed above)	≥3
	Infirmaries in correctional facilities [A]	≥3

A
Correctional facilities that have never reported active TB (tuberculosis) cases can be considered low risk.

HCW (healthcare workers) Activities

Patient care activities performed by HCW (healthcare workers)s are associated with varying degrees of exposure risk and subsequent infection with *M. tuberculosis* (Refer to section Risk categories for activities performed by health care workers). This risk increases with the duration of exposure and higher amounts of airborne mycobacteria. As a result, it is recommended that HCW (healthcare workers)s perform a risk assessment prior to interactions with people suspected of or confirmed as having active TB (tuberculosis) disease [16]. This risk assessment involves evaluating the likelihood of exposure to *M. tuberculosis* for a specific patient care activity, with a specific patient, in a specific environment and under particular conditions. This is referred to as a point-of-care risk assessment and is described in a recent publication from the Public Health Agency of Canada (PHAC) [16]. The assessment informs HCW (healthcare workers)s' decisions regarding the appropriate infection prevention and control measures needed to minimize the risk of exposure for themselves, other HCW (healthcare workers)s, patients and visitors.

Risk Categories for Activities Performed by Health Care Workers

- **High-risk activities**
  - Cough-inducing procedures (such as sputum induction)
  - Autopsy
  - Morbid anatomy and pathology examination
  - Bronchoscopy
  - Mycobacteriology laboratory procedures, especially handling cultures of *M. tuberculosis*
- **Intermediate-risk activities**
  - Work requiring regular direct patient contact on units (such as emergency departments) where patients with respiratory TB (tuberculosis) disease may be present [A]
  - Work in pediatric units where patients with TB (tuberculosis) may be admitted [B]
  - Cleaning of rooms of patients with respiratory TB (tuberculosis) disease
- **Low-risk activities**
  - Work requiring minimal patient contact (such as clerical, reception and administration)
  - Work on units where patients with respiratory TB (tuberculosis) disease are unlikely to be present [C]

A

This includes work done by all HCW (healthcare workers)s in these units.

B

Pediatric patients with respiratory TB (tuberculosis) disease should be considered infectious until infectiousness is ruled out by radiography and negative acid-fast bacteria sputum smears in patient, parents or caregivers. Refer to section "Isolation considerations for pediatric patients" in this chapter and Chapter 9, Pediatric Tuberculosis.

C

Classification of such units as low risk may be inaccurate if the population they are serving has a high incidence of TB (tuberculosis) (e.g. patients born or previously residing in countries with a high TB (tuberculosis) incidence or other at-risk populations). Some of the longest delays in diagnosis may occur in such settings.

Laboratory Personnel Handling *M. tuberculosis*

There are risks associated with handling *M. tuberculosis* in the laboratory that are not typically present in health care settings. Compared with the general population, laboratory HCW (healthcare workers)s have been found to have a greater risk of acquiring LTBI (latent TB infection) [7]. Although this risk stems mainly from aerosol formation during specimen or isolate manipulation, other mechanisms of transmission have been described in this setting. At the time of publication of these Standards, PHAC's Laboratory of Biosafety and Biosecurity was in the process of preparing a biosafety guideline, *Mycobacterium tuberculosis* Complex (MTBC (Mycobacterium tuberculosis Complex)) Biosafety Directive. Refer to Appendix D for details on laboratory standards. Recommendations on safe laboratory procedures, training programs, infection control plans, respiratory protection, TST (tuberculin skin testing) screening for personnel and safe transportation of samples are also available from other sources [7] [24] [25].

Prevention and Control of Transmission of *M. Tuberculosis*

Current recommendations for the prevention of health care associated transmission of *M. tuberculosis* involve a hierarchical approach to infection prevention and control measures, including the following:

- **Administrative controls** - institutional policies or measures that aim to reduce the time between the arrival of people with respiratory TB (tuberculosis) disease at a health care facility, diagnosis of their condition and placement in an airborne infection isolation room (AIIR (airborne infection isolation room) (airborne infection isolation room)). The purpose of these policies is to provide overarching protection for all HCW (healthcare workers)s, patients and visitors in a facility. Administrative control measures include occupational health programs incorporating skin testing of HCW (healthcare workers)s for LTBI (latent TB infection) after exposure and at regular intervals, access to treatment of LTBI (latent TB infection), exclusion of HCW (healthcare workers)s with respiratory TB (tuberculosis) disease, facility and unit risk assessments, as well as a HCW (healthcare workers) education program. Details on performing a risk assessment and on HCW (healthcare workers) education can be found elsewhere [7] [16].
- **Environmental (engineering) controls** - environmental measures to reduce the likelihood of exposure of HCW (healthcare workers)s, other patients and visitors to viable airborne *M. tuberculosis*. These include mechanical ventilation systems (to supply clean air) in patient care areas, use of ultraviolet germicidal irradiation (UVGI (ultraviolet germicidal irradiation)) and high-efficiency particulate air (HEPA (high-efficiency particulate air)) filters.
- **Personal protection controls** - measures directed to individual HCW (healthcare workers)s either to prevent infection (such as use of respirators) or to prevent disease if infected (such as detection and treatment of LTBI (latent TB infection)).

Each control measure is further explained below.

Administrative Controls within Hospitals

Recommendations

(*Conditional recommendations, based on very weak evidence*)

All hospitals, regardless of risk category, should have a TB (tuberculosis) Management Program (or TB (tuberculosis) Infection Prevention and Control Program) supported at the highest administrative level with components detailed below. This program may be facilitated through existing infection prevention and control programs with administrative responsibility clearly delineated.

Other health care settings may refer to the hospital TB (tuberculosis) Management Program to identify procedures that are applicable to the setting.

Tuberculosis Management Program

The goal of a TB (tuberculosis) management program is to prevent *M. tuberculosis* transmission to HCW (healthcare workers)s, patients and visitors.

Risk Assessment

The first step of an effective TB (tuberculosis) management program in a hospital or other health care setting should be to perform an organizational risk assessment in order to decrease the risk of patient and HCW (healthcare workers) exposure to and acquisition of *M. tuberculosis*. The exposure risk for HCW (healthcare workers)s engaged in different activities should be evaluated during this assessment. For further information on an organizational risk assessment, refer to a recent PHAC publication [16].

In hospitals of all risk categories, the following features should be in place as components of the TB (tuberculosis) management program:

- Policies and procedures should clearly delineate administrative responsibility for developing, implementing, reviewing and evaluating various program components. The evaluation should include quality control and audits for all components of administrative, environmental and personal protection controls. Personnel with responsibility for the program within the facility should be designated.
- Policies and procedures should be in place for rapid identification, isolation and treatment of patients; reduction of health care associated transmission through environmental controls; and protection of staff through appropriate use of personal protective equipment, education and TST (tuberculin skin testing).
- An annual review of the indices of health care associated transmission should be done. This includes (i) TST (tuberculin skin testing) conversion rates among HCW (healthcare workers)s; (ii) the total number of people with respiratory TB (tuberculosis) disease admitted annually; (iii) the number of occupational exposure episodes (i.e. admitted individuals with respiratory TB (tuberculosis) disease who were not placed under airborne precautions while receiving care); and (iv) the number of previously admitted patients whose TB (tuberculosis) was diagnosed only at autopsy.
- An annual summary of the clinical, epidemiologic and microbiologic features of patients whose TB (tuberculosis) is diagnosed within the hospital should be made available to HCW (healthcare workers)s caring for these patients. This will increase awareness of which patients in the population served are at risk of respiratory TB (tuberculosis) disease and the clinical manifestations.
- Additional considerations (such as higher index of suspicion or increased vigilance to prevent transmission before diagnosis) are recommended when caring for immunocompromised patients, whose infection may

carry a higher risk of progression from LTBI (latent TB infection) to active TB (tuberculosis) disease. This includes patients in oncology, HIV and haemodialysis units or clinics.

In hospitals that are not considered low risk (Table 1), the following additional items should be in place as components of the TB (tuberculosis) Management Program:

- The hospital Infection Prevention and Control Committee (or other appropriate existing committee) should be given responsibility for the TB (tuberculosis) management program. Committee members should include people with day-to-day responsibility for infection prevention and control. There should also be representation from senior administration; occupational health and safety; laboratory, nursing and medicine; and other health disciplines or groups as needed (e.g. respiratory technology, public health, central supply, housekeeping, laundry, pharmacy, physical plant and maintenance).

In low-risk hospitals (Table 1), the following additional items should be in place as components of the TB (tuberculosis) management program:

- The TB (tuberculosis) management program may consist of screening protocols for diagnosis in patients with symptoms of respiratory TB (tuberculosis) disease and pre-arrangement to transfer all such patients to another centre where appropriate environmental measures are available.
- In hospitals with a transfer-out policy, there should be at least one separate, well-ventilated area [26] or a single room with the door closed, away from high-risk patients, [16] where patients can be maintained until they are transferred.
- Hospital administrators in collaboration with appropriate jurisdictional authorities, should coordinate the planning of adequate numbers of hospitals with resources to receive such patients with minimum delay.

Education of HCW (healthcare workers)s

A very important component of any TB (tuberculosis) management program is education of HCW (healthcare workers)s on how to protect themselves from exposure to *M. tuberculosis*. HCW (healthcare workers)s should be educated about TB (tuberculosis) infection prevention and control measures at the time of hiring and periodically thereafter. Education for HCW (healthcare workers)s should be relevant to their duties. For health care professionals, this should include awareness of epidemiologic and medical risk factors for TB (tuberculosis), signs and symptoms of active TB (tuberculosis) disease (respiratory and nonrespiratory) and mechanisms of transmission. All HCW (healthcare workers)s, including orderlies, housekeeping and maintenance staff, should be educated to respect signage and to understand the importance of administrative, environmental and personal protection controls in the prevention of transmission.

Identification of Patients with Respiratory TB (tuberculosis) Disease Within Hospitals

Delayed diagnosis occurs in almost half of all hospitalized patients in whom respiratory TB (tuberculosis) disease is subsequently detected. This often results in significant exposure for HCW (healthcare workers)s and other patients. One study found that for each unrecognized case of respiratory TB (tuberculosis) disease, an average of 24 HCW (healthcare workers)s were exposed [27]. Certain locations within the hospital, such as emergency departments, are a frequent point of first contact with the health care system for people with undiagnosed respiratory TB (tuberculosis) disease [28] [29]. This was observed in a Canadian study: from 1994 to 1998, 47% of 250 people with TB (tuberculosis) made a total of 258 visits to emergency departments during the 6 months before their diagnosis [28].

Recommendations

(Conditional recommendations, based on strong evidence)

- A cough of 2- 3 weeks' duration with or without weight loss and fever in a person belonging to one of the at-risk groups below should prompt a thorough investigation to determine whether active respiratory TB (tuberculosis) is the cause: [7] [10]
    - People with a history of active TB (tuberculosis);
    - Staff and residents of homeless shelters;
    - The urban poor;
    - Staff and inmates of correctional facilities and previously incarcerated people;
    - Injection drug users;
    - Aboriginal Canadians residing in communities with high TB (tuberculosis) rates;
    - People infected with HIV (human immunodeficiency virus);
    - People born in Canada and other low TB (tuberculosis) incidence countries prior to 1966;
    - People born or previously residing in countries with a high TB (tuberculosis) incidence in Asia, Eastern Europe, Africa and Latin America;
    - People with high risk factors listed in Chapter 6, Table 1;
    - HCW (healthcare workers)s serving at-risk groups.

To consider someone a suspect for active respiratory TB (tuberculosis) disease (for investigation and/or initiation of airborne precautions), cough of 2 weeks duration is a more sensitive criterion, but cough of 3 weeks duration will be more specific. Selection of 2 or 3 weeks as the criterion depends on the local experience and epidemiology of TB (tuberculosis).

The TB (tuberculosis) incidence rate in Canada prior to 1966 was similar to that in a high TB (tuberculosis) incidence country (refer to Chapter 1, Epidemiology of Tuberculosis in Canada) thus the inclusion of this birth cohort as an at-risk group.

Concomitant respiratory TB (tuberculosis) disease should be ruled out in cases of nonrespiratory TB (tuberculosis). Refer to Chapter 2, Transmission and Pathogenesis of Tuberculosis, and Chapter 7, Nonrespiratory Tuberculosis.

Prompt diagnosis of active respiratory TB (tuberculosis) can be a major challenge if the clinical features of TB (tuberculosis) are atypical, such as negative AFB (acid-fast bacteria) sputum smears, non-cavitary lesions on chest radiograph and the absence of cough and sputum production [19]. Atypical features of respiratory TB (tuberculosis) disease are more frequently observed in the elderly and people who are immunocompromised because of medical conditions (renal failure, HIV (human immunodeficiency virus)) or therapy (steroids, anti-tumour necrosis factor). Refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance.

Airborne Precautions for Patients with Suspected or Confirmed Respiratory TB (tuberculosis) Disease

Recommendations

(Strong recommendations, based on strong evidence)

- Airborne precautions should be initiated as soon as possible for all those with suspected or confirmed respiratory TB (tuberculosis) disease who are admitted to a hospital.
- Patients (including children of any age) who show signs and symptoms of TB (tuberculosis), or whose respiratory secretions, e.g. sputum or bronchial alveolar lavage, have yielded AFB (acid-fast bacteria), or who have a chest radiograph indicative of active TB (tuberculosis) should be immediately isolated in an AIIR (airborne infection isolation room). Refer to Figure 1.

Recommendations

(Conditional recommendations, based on very weak evidence)

- Once airborne precautions have been initiated, the patient should remain in the AIIR (airborne infection isolation room) until isolation is discontinued by designated medical personnel. Patients kept under airborne precautions can leave an AIIR (airborne infection isolation room) for medical reasons.
- A patient may be allowed to leave an AIIR (airborne infection isolation room) but only if it can be ensured that he or she adheres to airborne precautions; these include the proper wearing of a mask.
- Refer to Figure 1 for detailed recommendations.

In the absence of an AIIR (airborne infection isolation room), the patient should be placed into a single room (with the door closed and a portable air filtration unit used if available) until transfer to a facility where an AIIR (airborne infection isolation room) is available. Airborne precautions also include the use of respirators by HCW (healthcare workers)s caring for patients with suspected or confirmed active TB (tuberculosis) disease.

Isolation Considerations for Pediatric Patients

If isolation in the hospital is necessary for young children (under 5) with suspected or confirmed respiratory TB (tuberculosis) disease, it should be noted that they likely acquired their disease from adult family contacts, who may pose a risk to HCW (healthcare workers)s and other patients while visiting. Thus, for these patients, considerations for infection prevention and control in the hospital should include potentially infectious family members [30] [31]. Visitors (limited to immediate adult family or guardians) should be screened by symptoms and radiography for active TB (tuberculosis) disease and should wear a mask during visits (when not in the AIIR (airborne infection isolation room)) until active TB (tuberculosis) disease is ruled out. Refer to Chapter 9, Pediatric Tuberculosis, for information on TB (tuberculosis) infection and disease in children.

Figure 1. Recommended steps for isolation for suspected or confirmed active respiratory TB (tuberculosis) disease in hospital[A]

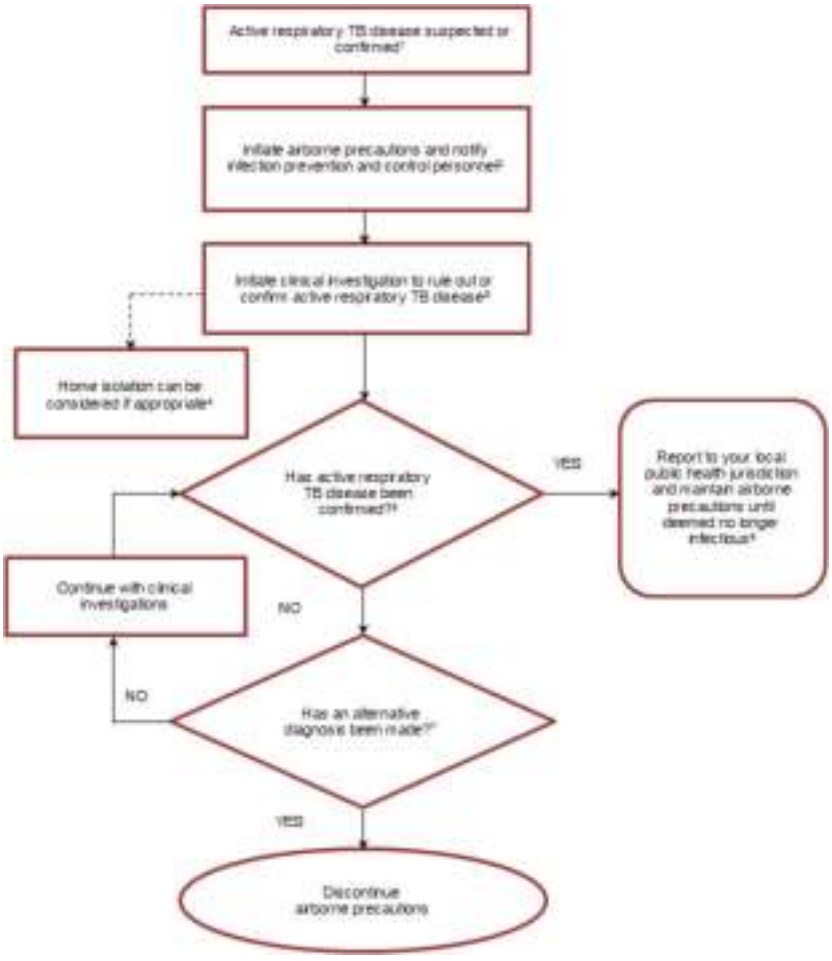

Figure 1. Legend

A) Includes infirmaries in correctional facilities

1) It is recommended that patients suspected of having active respiratory TB (tuberculosis) disease be isolated immediately rather than wait for confirmation of disease prior to initiating airborne precautions.

Airborne precautions are recommended during procedures that may generate aerosols from wound drainage in non-respiratory active TB (tuberculosis) disease.

Refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance.

2) Airborne precautions include (in addition to routine practices):

- placement in an AIIR (airborne infection isolation room);
- respirator use by healthcare workers and if deemed necessary, by visitors also;
- mask use by patient when out of AIIR (airborne infection isolation room);
- restriction of patient to AIIR (airborne infection isolation room) except for medically essential procedures;
- education of patient, families and visitors on the precautions.

Visitors should be restricted to immediate family or guardians. Visiting family or guardians of pediatric patients should be screened for active respiratory TB (tuberculosis) disease. Visits by children under age five and immunocompromised persons should be discouraged.

3) Cough inducing procedures (e.g., sputum specimen collection, sputum induction) should be performed in an AIIR (airborne infection isolation room).
Refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance, for details of clinical investigations.

4) Refer to Figure 2 Legend for conditions for home isolation.

5) The examination of smears of respiratory specimens for acid-fast bacteria is widely used as a presumptive rapid test, however mycobacterial culture provides a definitive diagnosis of active TB (tuberculosis) disease.

6) Airborne precautions may be discontinued when the patient has clinical evidence of improvement, three consecutive negative sputum smears for acid-fast bacteria and there is evidence of adherence to at least two weeks of effective therapy. Multi-drug resistant TB (tuberculosis) cases and those with mono-resistance to rifampin (RMP (rifampin)) should have three consecutive negative sputum cultures after six weeks of incubation prior to discontinuing airborne precautions.

7) Airborne precautions can be discontinued if another diagnosis is made (e.g., cancer, non-tuberculous pneumonia) and concomitant active respiratory TB (tuberculosis) disease is considered unlikely.

AIIR (airborne infection isolation room): airborne infection isolation room

Transport of Patients with Suspected or Confirmed Respiratory TB (tuberculosis) Disease

Recommendations

(Conditional recommendations, based on very weak evidence)

- Prior to transport, HCW (healthcare workers)s involved in patient transport, transport personnel and the receiving health care facility should be advised of the infectious state of the patient.
- Patients should be escorted by a HCW (healthcare workers) during transport/transfer of patients from one facility to another or within a facility.

- Patients with respiratory TB (tuberculosis) disease should wear a mask, and HCW (healthcare workers)s involved in transport should wear a respirator (Refer to section "Respirators and masks").
- If transport between facilities is required, patients should not use public transport.
- Patients should be transported in well-ventilated vehicles (i.e. with the windows open when possible).
- Where air transport is required (e.g. from remote settings), transport personnel should refer to their organization's policies on medical transport of patients with airborne infections.

Preventing Patient-to-Patient Transmission of *M. tuberculosis* Within Hospitals

Measures should be taken to reduce the risk of *M. tuberculosis* transmission to people within the hospital, including patients, HCW (healthcare workers)s, other staff, volunteers and visitors. Until placement in an AIIR (airborne infection isolation room), a patient with suspected or confirmed active respiratory TB (tuberculosis) should wear a mask as a source control measure to prevent viable *M. tuberculosis* from being disseminated (refer to section "Respirators and masks"). Source control measures, patient placement in a single room and limiting of patient movement all contribute to reducing the risk of patient-to-patient transmission [16]. When availability of single rooms is limited, priorities for placement of patients should be determined by risk assessment. Patients with suspected or confirmed respiratory TB (tuberculosis) disease have priority and should not share rooms with each other, since their strains and levels of infectivity may be different [16].

A review of HCW (healthcare workers)s' LTBI (latent TB infection) screening records for conversions as well as patient surveillance data and medical records for cases of respiratory TB (tuberculosis) disease can help to identify whether patient-to-patient transmission occurred before initiation of airborne precautions. This possibility should be considered under the following circumstances: [7]

- A high proportion of people with respiratory TB (tuberculosis) disease were admitted to or examined in the same setting during the year preceding onset of their disease.
- Isolates from multiple patients in the same health care facility have identical anti-mycobacterial susceptibility and molecular genotypes.
- An increase occurred in the number of people with drug-resistant respiratory TB (tuberculosis) disease compared with the previous year (applicable if the transmission was from a drug-resistant patient).

Refer to Chapter 12, Contact Follow-up and Outbreak Management in Tuberculosis Control, for further information.

Discontinuation of Airborne Precautions

Institutional policies should designate people with the authority (e.g. the infection prevention and control personnel) to discontinue airborne precautions as well as manage both breaches of and adherence to airborne precautions.

Recommendations

(*Strong recommendations, based on moderate evidence*)

Suspect TB (tuberculosis) cases

- Airborne precautions may be discontinued if three successive samples of sputum (spontaneous or induced) are negative on smear unless TB (tuberculosis) is still strongly suspected and no other diagnosis has been made [24] [32] [33].

Note: Where feasible, three sputum specimens (either spontaneous or induced) can be collected on the same day, a minimum of 1 hour apart with at least one of them taken in the early morning. As previously done, the evidence used to inform sputum collection recommendations for discontinuation of airborne precautions originates from

available studies related to diagnosis of respiratory TB (tuberculosis) disease. Refer Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance for the current evidence base.

A single negative AFB (acid-fast bacteria) smear from bronchial alveolar lavage does NOT definitively exclude respiratory TB (tuberculosis) disease; three induced sputa provide superior yield for the diagnosis and therefore are preferred to a single bronchoscopy. Refer Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance, for further explanation and references.

Confirmed TB (tuberculosis) cases

Although the degree and duration of infectiousness of patients after initiation of effective therapy remains unclear, it is known that effective therapy (i.e. therapy with two or more drugs to which the TB (tuberculosis) organisms are susceptible) will rapidly reduce cough and the number of viable bacteria in the sputum.
Note: Drug susceptibility test results are usually available within 4 weeks in a smear-negative, culture-positive case and 3 weeks in a smear-positive case; this confirms the effectiveness of therapy to date. Refer to Appendix D on Tuberculosis and Mycobacteriology Laboratory Standards: Services and Policies.

Recommendations
(*Strong recommendations, based on moderate evidence*)

Confirmed TB (tuberculosis) cases

- **Patients with smear-negative, culture-positive drug-susceptible respiratory TB (tuberculosis):**

  These patients should be kept under airborne precautions until there is clinical evidence of improvement and a minimum of 2 weeks of effective therapy has been completed. Patients may be discharged to home isolation for the period requiring airborne precautions provided there is clinical improvement, drug-resistant TB (tuberculosis) is not suspected and there is no contraindication for home isolation (refer to Figure 2).
- **Patients with smear-positive, culture-positive drug-susceptible respiratory TB (tuberculosis):**

  These patients should be kept under airborne precautions until there is clinical evidence of improvement, evidence of adherence to at least 2 weeks of effective multidrug therapy based on the known antibiotic sensitivity of the patient's organism, and three consecutive negative AFB (acid-fast bacteria) sputum smears [34]. Patients may be discharged to home isolation for the period requiring airborne precautions provided there is clinical improvement, drug-resistant TB (tuberculosis) is not suspected and there is no contraindication for home isolation (Figure 2).

Note: Specimens can be collected within 1 hour of each other on the same day, with at least one of them taken in the early morning. As previously done, the evidence used to inform sputum collection recommendations for discontinuation of airborne precautions originates from available studies related to diagnosis of respiratory TB (tuberculosis) disease. Refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance for the current evidence base. In patients who are no longer able to spontaneously produce a sputum specimen, sputum induction is useful and appropriate. More invasive testing, such as bronchoscopy, is not recommended for monitoring response to therapy.

Although smear-positive patients are still potentially infectious, their household contacts have already been heavily exposed and are often receiving therapy for LTBI (latent TB infection) when discharge from hospital is being considered. Thus, the risk of further transmission to these contacts should be balanced by the social, mental and physical health benefits of the patient's return home.

Recommendations

(*Strong recommendations, based on moderate evidence*)

Confirmed TB (tuberculosis) cases

- **Patients with persistent smear-positive sputa:** Patients may be discharged to home isolation for the period requiring airborne precautions provided there is clinical improvement, drug-resistant TB (tuberculosis) is not suspected and there is no contraindication for home isolation (Figure 2). If sputum specimens continue to be culture-positive after 4 months of anti-tuberculosis treatment or if culture results become positive after a period of negative results, drug susceptibility tests should be repeated and a TB (tuberculosis) expert consulted [7].
- **Patients known to have active multidrug-resistant TB (tuberculosis) or mono-resistance to RMP (rifampin)**: These patients should be kept under airborne precautions for the duration of their hospital stay or until three consecutive sputum cultures (not smears) are negative after 6 weeks of incubation. Also refer to Chapter 8, Drug-resistant Tuberculosis.

Figure 2. Recommended steps for isolation for suspected or confirmed active respiratory TB (tuberculosis) disease in the home

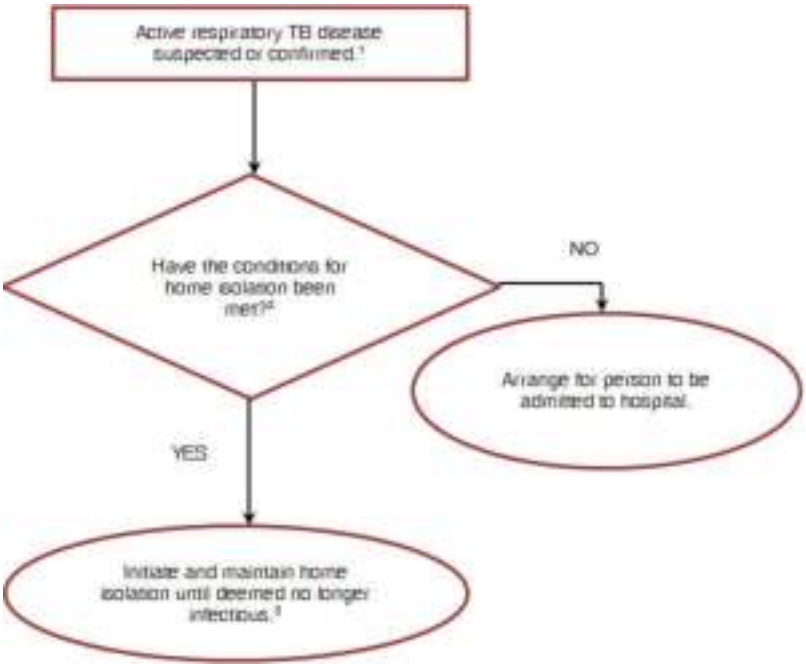

Figure 2. Legend

1) Refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance.
The person being assessed for active respiratory TB (tuberculosis) disease should wear a mask. HCW (healthcare workers)s should wear a respirator when sharing a common airspace with the person.

2) Conditions for home isolation:

- Supervised therapy, if indicated, has been arranged;
- The person does not share a common airspace with non-household members (e.g., rooming house) and the household air is not being recirculated to other housing units (e.g., apartment complex);
- All household members have been previously exposed to the person. If any household members are TST (tuberculin skin testing) negative, they should be informed and understand the potential risks;

- No children under the age of 5 or persons with immunocompromising conditions are present in the home (an exception would be if they are receiving prophylaxis or treatment for active TB (tuberculosis) disease or latent TB (tuberculosis) infection);
- No visitors should be allowed in the home except for HCW (healthcare workers)s;
- The person is counselled on and is willing and able to comply with limitations to their movement outside of the home (e.g., does not go to work, school or any other public indoor environment);
- The person should not be allowed to use any form of public transportation (if absolutely necessary, a taxi can be used to attend essential healthcare appointments provided the person is wearing a mask);
- The person should be allowed to ambulate outdoors since the risk of transmission is negligible provided they are not in very close contact with susceptible individuals for prolonged periods of time.

3) Home isolation may be discontinued when the patient has clinical evidence of improvement, three consecutive negative sputum smears for acid-fast bacteria and there is evidence of adherence to at least 2 weeks of effective therapy. Multi-drug resistant TB (tuberculosis) cases and those with mono-resistance to RMP (rifampin) should have three consecutive negative sputum cultures after 6 weeks of incubation prior to discontinuing home isolation. HCW (healthcare workers)s: health care workers.

Environmental (Engineering) Controls Within Hospitals

Ventilation Guidelines

Ventilation recommendations for AIIR (airborne infection isolation room)s and select areas in hospitals are of critical importance because of their impact on reducing the risk for health care associated transmission of *M. tuberculosis*. Increasing air changes per hour (ACH (air changes per hour)) from 1 ACH (air changes per hour) to 6 ACH (air changes per hour) will result in four to five times more rapid clearing of infectious microorganisms from the air within a room. However, further increases above 6 ACH (air changes per hour) will have progressively less effect, and increases above 12 ACH (air changes per hour) may provide minimal additional benefit [29] [35]. In general, as air exchange rates are increased, there are increased costs for building and maintaining the ventilation system.

A number of recognized organizations have made recommendations regarding ventilation levels to reduce the risk of health care associated transmission of airborne pathogens, including *M. tuberculosis* and varicella-zoster viruses [7] [36] [37]. These organizations have published different ventilation standards for AIIR (airborne infection isolation room)s and other patient care areas within hospitals (refer to Table 2). Differences among these recommendations are not based on consideration of different evidence but, rather, on the risk-benefit assessment of each organization. Refer to Table 2 for current ventilation recommendations by different organizations.

General hospital areas

It is important to ensure that there is adequate ventilation in general (i.e. non-isolation) areas such as inpatient rooms and examination or treatment rooms. This is because people with unsuspected respiratory TB (tuberculosis) disease may be placed in them, posing a risk of transmission to other patients and HCW (healthcare workers)s [1]. Recent literature on room ventilation rates has not provided definitive evidence for the ideal number of ACH (air changes per hour) to prevent transmission of TB (tuberculosis) in non-isolation rooms within hospitals [38].

Airborne infection isolation rooms (all hospitals except low risk with transfer-out policy)

Measures to ensure that adequate ventilation is in place are outlined below and are also discussed in more detail in other guidelines [7] [16].

Recommendations

(Strong recommendations, based on moderate evidence)

- With the exception of rooms in which operative procedures are done, the direction of air flow should be inward from the hall into the room (negative pressure), and then the air should be exhausted outdoors. If an anteroom is used, the air from both the anteroom and patient room should be exhausted outdoors [16]. To achieve this, the ventilation system should be designed to function such that the anteroom and/or the AIIR (airborne infection isolation room) are at lower pressure relative to the hallway outside. An anteroom is not essential if the pressure differential is adequate. Refer to the CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention)'s recent recommendations on pressure differentials [7].
- Windows and doors should be kept closed at all times, including during and after aerosol-generating procedures (long enough for air clearance in the room). Opening the window may cause reversal of the direction of air flow, depending upon the prevailing wind direction and outdoor temperature.
- Air should be exhausted to the outdoors through a dedicated exhaust system, ideally exiting from the roof of the building. It is important that the exhausted air does not re-enter the building or an adjacent occupied building. If the air will be recirculated, or if the exhausted air could re-enter the building, it should be passed through a HEPA (high-efficiency particulate air) filter before being exhausted [7]. Within existing facilities, use of HEPA (high-efficiency particulate air) filtration units that recirculate air back into the room and/or ultraviolet germicidal irradiation (which has bactericidal activity against *M. tuberculosis)* may be adjunctive methods to remove or reduce viable airborne *M. tuberculosis*; these are discussed later in this chapter.
- The rate of air changes and direction of air flow should be verified at least every 6 months when the room is not being used as an AIIR (airborne infection isolation room). When the AIIR (airborne infection isolation room) is in use, the direction of air flow should be verified daily using electronic pressure monitors, and should be recorded. Where electronic monitors are unavailable, such as in older buildings, in resource-constrained settings or in temporary isolation settings, smoke tubes placed at all four corners of the door can be used [16].
- The number of AIIR (airborne infection isolation room)s required in hospitals not considered low risk should be based on the number of patients admitted each year with suspected respiratory TB (tuberculosis) disease. In organizations with very few admissions for TB (tuberculosis), the number of AIIR (airborne infection isolation room)s should be decided by the organizational authorities according to an analysis of AIIR (airborne infection isolation room) utilization in the previous 2 or 3 years. The Canadian Thoracic Society suggests one or two more AIIR (airborne infection isolation room)s than what was needed in the past at peak times. Appropriate resources should be made available to hospitals that will have such rooms and therefore receive patients with respiratory TB (tuberculosis) disease.

Sputum induction and administration of aerosolized pentamidine (all hospitals)

Recommendations

(Strong recommendations, based on moderate evidence)

- The smaller the room where these procedures are performed the easier and more practical it is to achieve required ventilation levels. Ideally, specially constructed "booths" (which are commercially available) should be used.
- Doors and windows should remain closed during and after the procedure, long enough for air clearance in the room (refer to Table 3).
- The air should be exhausted through a dedicated exhaust system or HEPA (high-efficiency particulate air) filtered.

Bronchoscopy and autopsy (all hospitals)

Areas where these procedures are performed tend to be much larger, making it difficult to achieve consistently high levels of ventilation with an inward direction of air flow. The increased risk of transmission associated with these activities warrants the significant expenditures required to achieve higher ventilation requirements.

Recommendations

(Strong recommendations, based on moderate evidence)

- Doors and windows should remain closed during and after the procedure, long enough for air clearance in the room (refer to Table 3).
- The air should be exhausted through a dedicated exhaust system or HEPA (high-efficiency particulate air) filtered.

Table 2. Ventilation recommendations for selected areas in health care facilities

Area	Number of mechanical air changes per hour Recommending agency				Direction of air movement (all agencies) [A]
	CTS (Canadian Thoracic Society) (2013)	CSA (2010)	CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) (2005)	ASHRAE (2008) in FGI (2010)	
Autopsy suite	12	20	12	12	Inward

Area	Number of mechanical air changes per hour Recommending agency				Direction of air movement (all agencies) [A]
	CTS (Canadian Thoracic Society) (2013)	CSA (2010)	CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) (2005)	ASHRAE (2008) in FGI (2010)	

CTS (Canadian Thoracic Society)
Canadian Thoracic Society

CSA
Canadian Standards Association [36]

CDC (Centers for Disease Control and Prevention)
US Centers for Disease Control and Prevention [7]

ASHRAE
American Society of Heating Refrigeration and Air-conditioning Engineers [37]

FGI
Facilities Guidelines Institute [37]

A
Direction of airflow from hallway or corridor relative to space; inward means from hallway into room. The US CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) provides further detail on direction of airflow specific to some inpatient settings, such as emergency departments and surgical suites/operating rooms [7].

B
Six ACH (air changes per hour) for existing room and 12 ACH (air changes per hour) for new constructions.

C
Note that the CTS (Canadian Thoracic Society) recommendations for these areas were developed following a systematic review of the available evidence on ventilation rates for preventing transmission of *M. tuberculosis*. The scope of the review included general hospital areas, emergency departments, as well as trauma and radiology waiting rooms.

D
Air-cleaning devices may be used to increase the equivalent ACH (air changes per hour).

E
Portable or fixed HEPA (high-efficiency particulate air) filtration units may be used as a temporary measure to help older facilities achieve the minimum required number of air exchanges per hour, but the facilities should be considered for upgrade. Refer to CSA document for details [36].

F
Portions of a structure can be renovated if facility operation and patient safety in the renovated areas are not jeopardized by existing features of sections retained without complete corrective actions. Refer to ASHRAE document for details [37].

G
Not stated, no recommendation made specific to these areas.

H
Recommendation is for patient corridor.

Note that the CTS (Canadian Thoracic Society) ventilation recommendations in Table 2 should be considered a minimum, as the CSA recommends higher ventilation rates for all areas. The CTS (Canadian Thoracic Society) recommendations were developed on the basis of a systematic review of currently available published evidence. Specific ACH (air changes per hour) rates are not recommended here; rather, Table 2 provides health care organizations with current recommendations provided by various organizations. In deciding which recommendations to implement, hospital administrators may need to take into account factors such as resources, facility design and available scientific evidence. The current paucity of evidence for adequate ACH (air changes per hour) rates to prevent transmission of *M. tuberculosis* and gaps in existing literature indicate that further research is needed in this area.

Entering rooms after generation of infectious aerosols has ended or patient with respiratory TB (tuberculosis) disease has been discharged

Health care workers often ask when it is safe to enter a room previously occupied by a patient with respiratory TB (tuberculosis) disease without needing to wear a respirator or when a procedure room can be used for another patient after generation of infectious aerosols has ceased. As shown in Table 3, this is dependent upon the level of ventilation in the room (expressed as ACH (air changes per hour)), if room sizes are relatively similar.

Table 3. Time needed (by number of air changes per hour) to remove airborne microorganisms after generation of infectious droplet nuclei has ceased [A]

Air changes per hour	Minutes required for removal of airborne microorganisms	
	99% removal	99.9% removal
2	138	207
4	69	104
6	46	69
12	23	35
15	18	28
20	14	21
50	6	8

A
This table was adapted from the CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) recommendations [7].

The values apply to a room in which the generation of aerosols has ceased, and ongoing mixing of the air in the room is assumed. Consideration should also be given to keeping the relative humidity of the air in the hospital at ≤60%. This range has been cited to minimize environmental contamination and provide acceptable indoor air quality [7].

Cleaning of rooms

If a room previously occupied by a patient with respiratory TB (tuberculosis) disease has been ventilated for the appropriate amount of time (refer to Table 3), the routine hospital cleaning procedures used in non-isolation rooms may be used for terminal cleaning of AIIR (airborne infection isolation room)s [7] [16]. If a room is still in use during cleaning, housekeeping personnel should wear a respirator (refer to section "Respirators and masks" below).

Ultraviolet Germicidal Irradiation

There is good evidence that short wave ultraviolet germicidal irradiation (UVGI (ultraviolet germicidal irradiation)) has excellent bactericidal activity against *M. tuberculosis* and can reduce infectious droplet concentrations by an amount equivalent to ventilation with 20 ACH (air changes per hour), depending upon the room volume and type of lights used [39]. Upper-room UVGI (ultraviolet germicidal irradiation) is considered a supplement or adjunct to ventilation [40]. Use of UVGI (ultraviolet germicidal irradiation) has been controversial because of potential skin cancer and eye damage. However, the risk of skin cancer with new, commercially available UVGI (ultraviolet germicidal irradiation) units is essentially eliminated. Possible eye complications can be avoided by proper installation of these units above head height, as well as a schedule of regular inspection and maintenance. A detailed review of the use of UVGI (ultraviolet germicidal irradiation) was published in 2010 [41]. This technology is being used with increasing frequency in settings such as homeless shelters to reduce airborne infectious microorganisms without the cost of renovating the heating, ventilation and air conditioning (HVAC (heating, ventilation and air conditioning)) system. For further information on the safe and effective use of UVGI (ultraviolet germicidal irradiation), including proper installation above head height and maintenance, refer to the recent CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) guidance document for using upper-room UVGI (ultraviolet germicidal irradiation) to control spread of *M. tuberculosis* in health care settings [40]. Use of UVGI (ultraviolet germicidal irradiation) may be considered in bronchoscopy and sputum induction rooms, emergency departments, autopsy areas and HIV (human immunodeficiency virus) clinics if ventilation is inadequate and cannot be upgraded. It can also be used where exposure is unpredictable, such as emergency departments in hospitals that are not considered low risk (refer to Table 1).

High-efficiency Particulate Air (HEPA (high-efficiency particulate air)) Filtration

HEPA (high-efficiency particulate air) filtration can be used to filter the exhaust from airborne infection isolation rooms, bronchoscopy suites or rooms where sputum induction is performed. Small HEPA (high-efficiency particulate air) units, either fixed or portable, may also be used to filter recirculated air in a room without the need for an increase in the amount of outdoor air supplied. HEPA (high-efficiency particulate air) filters require careful monitoring and regular change, as clogged filters will result in decreased efficacy. People performing maintenance and replacing filters on any ventilation system that is probably contaminated with *M. tuberculosis* should wear a respirator [7] (refer to section "Respirators and masks"). For further information on HEPA (high-efficiency particulate air) filtration and details on safety issues when handling spent filters, refer to the CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) guidelines [7].

With both UVGI (ultraviolet germicidal irradiation) and HEPA (high-efficiency particulate air) filtration environmental controls, regular maintenance (including procedures for installation, removal and disposal) and corresponding documentation are necessary.

Personal Protection Controls Within Hospitals

Personal protection controls are the final level in the hierarchy of control measures for preventing health care associated transmission of *M. tuberculosis.*

Respiratory Protection Program

Respiratory protection is one element of personal protection control measures. All hospitals should have a respiratory protection program in place. An essential component of the program involves selecting appropriate NIOSH (National Institute for Occupational Safety and Health)-certified respirators for HCW (healthcare workers)s, as discussed below. For cost-efficiency purposes, it is also important to provide respirator models with inherently

good fit characteristics, as these have been shown to fit more than 90% of workers [42] [43]. The health care organization should ensure that appropriate respirators are available as needed for use by HCW (healthcare workers)s, other staff and visitors, contractors, etc., and that masks, as needed for use by patients with respiratory TB (tuberculosis) disease, are available.

Another essential component of a hospital respiratory protection program is education of HCW (healthcare workers)s regarding the occupational risk of TB (tuberculosis) and the role of respiratory protection in reducing that risk.

Respirators and Masks

Respiratory protection of HCW (healthcare workers)s involves the use of a respirator with a filter class equivalent to or higher than an N95, to prevent inhalation of aerosols containing infectious microorganisms. The most widely used respirators by HCW (healthcare workers)s in North America are the NIOSH (National Institute for Occupational Safety and Health)-certified half-facepiece disposable respirators with an N95 filter class, commonly referred to as N95 respirators [15] [16]. These respirators are certified to filter 95% of particles of diameter 0.3 microns (µm) or larger with less than a 10% leak, thus protecting wearers against airborne infectious microorganisms such as *M. tuberculosis.* [7] [44]

A mask (either surgical or procedure) is used as a physical barrier. Masks are worn by HCW (healthcare workers)s to protect their skin and mucous membranes (nose and mouth) from droplets from an infected patient (or source). Masks are not designed for respiratory protection of HCW (healthcare workers)s as they are less than 50% effective in filtering small droplet nuclei (1-5 microns) containing *M. tuberculosis* [45].

Masks worn by patients with respiratory disease serve as a source control measure to trap the droplets that these patients expel. There is concern that because masks are loose-fitting they may allow the escape of airborne droplets (particularly during coughing); tight-fitting respirators, on the other hand, may be uncomfortable for patients (particularly those with limited respiratory reserve).

It is recommended that in all hospitals, including those with a transfer-out policy for cases of active TB (tuberculosis) disease, N95 respirators should be available for HCW (healthcare workers)s whenever a patient is suspected of or confirmed to have respiratory TB (tuberculosis) disease. This is particularly important because most low-risk hospitals will not have AIIR (airborne infection isolation room)s in which to house patients while awaiting transfer.

Fit Testing

Fit testing is used to determine whether a particular size and model of respirator fits a given person by assessing leakage around the face-respirator seal. Each time HCW (healthcare workers)s put on a respirator, a user seal check (according to manufacturer's instructions) is required to determine whether the respirator is properly sealed to the face. When TB (tuberculosis) patients are housed in AIIR (airborne infection isolation room)s, the contribution of respirators in preventing TB (tuberculosis) transmission to HCW (healthcare workers)s appears to be minimal [46]. Hence, despite published literature on fit testing [47] [49] there is insufficient evidence showing that a fit testing program results in reduced risk of health care associated transmission of *M. tuberculosis*. Nevertheless, most Canadian jurisdictions require fit testing for HCW (healthcare workers)s to determine their ability to obtain a satisfactory seal during respirator use [50]. HCW (healthcare workers)s are referred to jurisdictional requirements regarding the processes and frequency of fit testing. In the absence of requirements, consult provincial/territorial public health authorities.

Respirator recommendations for HCW (healthcare workers)s

(Strong recommendations, based on strong evidence)

- NIOSH (National Institute for Occupational Safety and Health) (National Institute for Occupational Safety and Health)-certified respirators (N95 or higher filter class) should be used by HCW (healthcare workers)s providing care to patients with suspected or confirmed respiratory TB (tuberculosis) disease.
- NIOSH (National Institute for Occupational Safety and Health) (National Institute for Occupational Safety and Health)-certified respirators (N95 or higher filter class) should be used by HCW (healthcare workers)s involved in the transport of patients suspected of or confirmed as having respiratory TB (tuberculosis) disease, e.g. paramedics.
- Refer to jurisdictional requirements for fit testing of respirators.

Mask recommendations for patients

(Strong recommendations, based on strong evidence)

- Masks should be used by patients with suspected or confirmed respiratory TB (tuberculosis) disease when leaving their AIIR (airborne infection isolation room)s.
- Masks should be used by patients with suspected or confirmed respiratory TB (tuberculosis) disease during transfer to a different location.

Screening for LTBI (latent TB infection) as Part of Infection Prevention and Control in Hospitals

Baseline TST (tuberculin skin testing) (all HCW (healthcare workers)s in all health care facilities)

The importance of conducting proper baseline TST (tuberculin skin testing) for all potentially exposed HCW (healthcare workers)s in all health care settings cannot be overemphasized. At the time of employment, many HCW (healthcare workers)s may already be TST (tuberculin skin testing) positive because of prior exposure, particularly HCW (healthcare workers)s born or previously residing in countries with high TB (tuberculosis) incidence who may have been exposed and infected before moving to Canada. In addition, older Canadian-born HCW (healthcare workers)s in some provinces/territories may have received bacille Calmette-Guérin (BCG) vaccination, which can interfere with TST (tuberculin skin testing) results. Prior exposure to *M. tuberculosis,* nontuberculous mycobacterial infection or BCG vaccination can result in a boosting phenomenon that is misdiagnosed as a TST (tuberculin skin testing) conversion. The occurrence of boosting phenomena has been documented in 3% to 10% of Canadian HCW (healthcare workers)s [13] [51]. Therefore, a two-step TST (tuberculin skin testing) is recommended (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection). PHAC has developed a compendium of the expected prevalence of TST (tuberculin skin testing) positivity in various Canadian populations; refer to Chapter 12, Contact Follow-up and Outbreak Management in Tuberculosis Control, for a summary table from the compendium.

Periodic TST (tuberculin skin testing) (specific clinical personnel in hospitals not considered low risk or those performing high-risk activities in all health care settings)

Recommendations for serial screening of specific HCW (healthcare workers)s for LTBI (latent TB infection) are given in the box below. Periodic TST (tuberculin skin testing)s should not be performed on previously TST (tuberculin skin testing)-positive HCW (healthcare workers)s as there is no value in doing so; rather, they should be referred for medical evaluation by a physician experienced in TST (tuberculin skin testing) interpretation and treatment of LTBI (latent TB infection), and should also be educated on the signs and symptoms of active TB (tuberculosis) disease (refer to Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance). Information on performing a TST (tuberculin skin testing), the definition of skin test conversion and management of the TST (tuberculin skin testing)-positive worker can be found in Chapter 4. Diagnosis of Latent Tuberculosis Infection.

Post-exposure TST (tuberculin skin testing) (all hospitals)

Any HCW (healthcare workers) who has unprotected exposure (termed an exposure episode) to a patient eventually confirmed to have respiratory TB (tuberculosis) disease should be considered at risk of having been infected. This includes situations in which a patient with undiagnosed respiratory TB (tuberculosis) disease was not in an AIIR or was cared for by a HCW (healthcare workers) who was not wearing a respirator. Exposure could also occur when such patients are not treated for a sufficient amount of time or with an effective regimen before isolation is discontinued.

Recommendations for screening HCW (healthcare workers)s for LTBI (latent TB infection)
(Strong recommendations, based on moderate evidence)

- Baseline two-step TST (tuberculin skin testing) for all HCW (healthcare workers)s upon starting work. An exception applies where documented results of a prior two-step TST (tuberculin skin testing) exist, in which case a single-step TST (tuberculin skin testing) should be given and prior TST (tuberculin skin testing) results transcribed into the HCW (healthcare workers)'s health record.
- Annual TST (tuberculin skin testing) for HCW (healthcare workers)s (with negative baseline TST (tuberculin skin testing)s) involved in intermediate-risk activities in health care settings not considered low risk and those involved in high-risk activities in all health care settings (refer to Tables 2 and 3).

Note: After 2 or more years of annual screening, if the annual risk of infection (based on TST (tuberculin skin testing) conversion rate in those screened) is shown to be less than 0.5%, consideration could be given to reducing the frequency of screening to every other year or to developing criteria that restrict annual screening to fewer workers who are at higher risk, and not testing the remaining workers except after exposure.

Recommendations for screening HCW (healthcare workers)s for LTBI (latent TB infection)
(Strong recommendations, based on moderate evidence)

Post-exposure:

- Single TST (tuberculin skin testing) 8 weeks after exposure for TST (tuberculin skin testing)-negative HCW (healthcare workers)s exposed to people with respiratory TB (tuberculosis) disease without adequate protection.
- For previously TST (tuberculin skin testing)-positive HCW (healthcare workers)s exposed to people with respiratory TB (tuberculosis) disease without adequate protection:
  - Refer for medical evaluation and educate on signs and symptoms of active TB (tuberculosis) disease. Refer Chapter 3, Diagnosis of Active Tuberculosis and Drug Resistance.
  - For HCW (healthcare workers)s with a history of BCG (Bacille Calmette-Guérin) vaccination, refer Chapter 4, Diagnosis of Latent Tuberculosis Infection, for information on the use of interferon-gamma release assays.

Protocols for TST (tuberculin skin testing) can be found in Chapter 4, Diagnosis of Latent Tuberculosis Infection.

Any HCW (healthcare workers) who has unprotected exposure (termed an exposure episode) to a patient eventually confirmed to have respiratory TB (tuberculosis) disease should be considered at risk of having been infected. This includes situations in which a patient with undiagnosed respiratory TB (tuberculosis) disease was not in an AIIR (airborne infection isolation room) or was cared for by a HCW (healthcare workers) who was not wearing a respirator. Exposure could also occur when such patients are not treated for a sufficient amount of time or with an effective regimen before isolation is discontinued.

Interferon-gamma release assay (IGRA (Interferon-gamma release assay))

The use of IGRA for serial (repeated) testing of HCW (healthcare workers)s is not recommended because serial testing studies have shown high rates of conversions and reversions, unrelated to exposure or treatment. There is no consensus on the appropriate cut-offs for deciding on IGRA conversions and reversions, and data show substantial variability in IGRA results around the cut-off used for LTBI (latent TB infection) diagnosis. Thus, TST (tuberculin skin testing) is the preferred test for serial testing for new LTBI (latent TB infection) (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, for details).

IGRAs may be useful for confirming a positive TST (tuberculin skin testing) in low-risk HCW (healthcare workers)s who are found positive on baseline TST (tuberculin skin testing) as part of their pre-employment screening.

BCG vaccination

The efficacy of BCG vaccination against *M. tuberculosis* has varied from zero to more than 80% in randomized controlled trials [52]. As a result, it is not recommended that HCW (healthcare workers)s be routinely vaccinated with BCG. Refer to Chapter 16, Bacille Calmette-Guérin (BCG) Vaccination in Canada, for details about the vaccine. The issue more relevant to most health care settings in Canada is how to interpret a positive TST (tuberculin skin testing) or IGRA when there is a history of BCG vaccination in adulthood (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, for information on this). Also, refer to The Online TST (tuberculin skin testing)/IGRA interpreter External Link. A summary of the provincial and territorial usage of BCG over time is available from PHAC at the Tuberculosis Prevention and Control External Link website and a BCG world atlas is available at BCG World Atlas: A Database of Global BCJ Vaccination Policies and Practices External Link.

Adherence to TB (tuberculosis) Infection Prevention and Control Measures

Low adherence to TB (tuberculosis) infection prevention and control measures by HCW (healthcare workers)s and to treatment of LTBI (latent TB infection) by both HCW (healthcare workers)s and patients will impede TB (tuberculosis) prevention efforts. Pre-employment screening for active TB (tuberculosis) disease is not sufficient to prevent *M. tuberculosis* transmission incidents involving HCW (healthcare workers)s in health care settings. Periodic HCW (healthcare workers) screening, recommended as above, and a high index of suspicion coupled with early assessment of HCW (healthcare workers)s with symptoms suggestive of TB (tuberculosis) are needed. Employers have reported greater success in encouraging HCW (healthcare workers)s to participate in screening programs when they are performed in conjunction with some other required activity (e.g. orientation, WHMIS (Workplace Hazardous Materials Information System) [Workplace Hazardous Materials Information System] training, employee updates, vaccination days) [14]. Administrative controls such as HCW (healthcare workers) training and education, in addition to a convenient schedule and location for screening, can increase adherence to TB (tuberculosis) infection prevention and control measures [7] [53].

Infection Prevention and Control of *M. Tuberculosis* in Specific Units and Populations Within Hospitals

Specific Units

All patients exhibiting signs and symptoms of TB (tuberculosis) in a hospital setting should be assessed to rule out active TB (tuberculosis) disease. In certain units, special consideration is required to prevent the transmission of TB (tuberculosis) to HCW (healthcare workers)s, other patients and visitors. A unit that treats or cares for at-risk patients (e.g. chemotherapy, HIV and dialysis units) should have a plan in place for how it will manage a patient with respiratory TB (tuberculosis) disease so that the patient's treatment is not interrupted and other people are not exposed.

Recommendations for Screening HCW (healthcare workers)s for LTBI (latent tuberculosis infection)
(Strong recommendations, based on strong evidence)

- **Intensive care unit (ICU (Intensive care unit)):** Every patient with suspected or confirmed respiratory TB (tuberculosis) disease who requires care in an ICU should be placed in an appropriately ventilated AIIR (airborne infection isolation room) within the ICU. If this is not available, arrangements should be made to transfer the patient to a facility with an AIIR (airborne infection isolation room) within the ICU as quickly as possible. For patients requiring intubation and mechanical ventilation, an appropriate bacterial filter should be placed on the endotracheal tube to prevent contamination of the ventilator and the ambient air [16]. When endotracheal suctioning is performed a closed suction apparatus should be used.
- **Emergency department:** A high index of suspicion for TB (tuberculosis) is required when assessing patients presenting with signs and symptoms of respiratory TB (tuberculosis) disease. Such patients should be immediately transferred to an AIIR (airborne infection isolation room). If such a room does not exist within the emergency department but exists elsewhere in the hospital, patients should be promptly transferred to this room until respiratory TB (tuberculosis) disease has been excluded (refer to section "Transport of patients with suspected or confirmed active respiratory TB (tuberculosis)").
- **Surgery:** Surgery should either be postponed (if feasible) until the TB (tuberculosis) patient is no longer considered infectious or scheduled to allow adequate ventilation of the room after surgery (refer to Table 3). Surgery is sometimes required in patients with multidrug-resistant or extensively drug resistant TB (tuberculosis), or to drain tuberculous abscesses. Because of the presence of infectious mycobacteria (and anaesthesia gases), the air supplied to the operating room should be exhausted to the outside and not exit the room to other patient care areas. HCW (healthcare workers)s should wear appropriate respirators (refer to section "Respirators and masks"). Post-operative recovery of the patient with suspected or confirmed respiratory TB (tuberculosis) disease should take place in the operating room or in an AIIR (airborne infection isolation room).

Special Populations

There are certain individuals whose immunocompromising conditions or immunosuppressive therapy places them at higher risk of progression from LTBI (latent TB infection) to active TB (tuberculosis) disease [7] [54]. They include HIV-infected individuals, transplant patients, people undergoing anti-tumour necrosis factor therapy and those undergoing dialysis or treatment for renal disease. A high incidence of LTBI (latent TB infection) and anergy has been reported among patients with chronic renal failure requiring dialysis [55] [56]. The risk of active TB (tuberculosis) disease in this population appears to be high in the first 6 to 12 months after dialysis is initiated [56]. Providing care for patients in a specialized clinic or in other settings might require special considerations, a higher index of suspicion for respiratory TB (tuberculosis) disease or increased vigilance to prevent transmission before diagnosis. Refer to Chapters 10 and 13 for further information. The CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) provides guidance on infection prevention and control considerations for dialysis units [7].

Prevention of Transmission of *M. Tuberculosis* Within Other Health Care Settings

Although the principles of TB (tuberculosis) infection prevention and control are the same across the continuum of health care, there is variation in the risk associated with different settings, and thus modification of the control measures applied is required. The availability of control measures needs to be considered when recommending interventions to prevent transmission of TB (tuberculosis) in non-hospital health care settings.

Long-term Care Facilities

Long-term care (LTC (long-term care)) facilities include homes for the aged, nursing homes, chronic care facilities, hospices, retirement homes, designated assisted living centres and any other collective living centre. Residents of LTC (long-term care) facilities are considered to be at the same risk as other populations in the community, with the exception of those belonging to at-risk groups (Refer to "Identification of patients with active respiratory TB (tuberculosis) within hospitals"). Due to the decreasing utility of TST (tuberculin skin testing) to diagnose LTBI (latent TB infection) after age 65 and the increasing risk of adverse effects from LTBI (latent TB infection) treatment in this age group, screening with a posterior-anterior and lateral chest x-ray for active TB (tuberculosis) is preferred upon admission for those over 65 years old. Refer to Chapter 12, Contact Follow-up and Outbreak Management in Tuberculosis Control, for further discussion and references. A baseline 2-step TST (tuberculin skin testing) is still recommended upon admission for those 65 years old and under who also belong to an identified at-risk group. Detailed screening recommendations for both HCW (healthcare workers)s and residents in LTC (long-term care) facilities are provided in Table 4.

Ambulatory Care/Outpatient Clinics

Ambulatory care settings include locations where health services are provided to patients who are not admitted to inpatient hospital units. This includes, but is not limited to, outpatient diagnostic and treatment facilities (e.g. diagnostic imaging, phlebotomy sites, pulmonary function laboratories, TB (tuberculosis) treatment facilities), community health centres or clinics, physician offices and offices of allied health professionals (e.g. physiotherapists) [7] [16]. If the patient mix includes members of at-risk populations, a high index of suspicion should be maintained for the presence of respiratory TB (tuberculosis) disease. Refer to section "Identification of patients with active respiratory TB (tuberculosis) within hospitals" for a description of this population.

Recommendations

(Conditional recommendations, based on weak evidence)

- If possible, visits by people with suspected or confirmed respiratory TB (tuberculosis) disease should be postponed until no longer infectious.
- If a visit cannot be postponed, it should be scheduled at the end of the day to minimize exposure to others, and, when possible, staff should be alerted of these visits to allow for prompt use of precautions [16].
- The patient should be provided with a mask before arrival or immediately upon reception to be worn until an AIIR (airborne infection isolation room) becomes available. If unavailable, the patient should be temporarily assessed or treated in a single room with the door closed, away from vulnerable patients, and transferred as soon as medically feasible to a facility with AIIR (airborne infection isolation room)s if admission is required [16].
- HCW (healthcare workers)s caring for people with suspected or confirmed respiratory TB (tuberculosis) disease in outpatient clinics should wear a respirator (Refer to section "Respirators and masks").
- Refer to Table 4 for further infection prevention and control recommendations for this setting.

Paramedics and Other Emergency Medical Services

Exposure to airborne infectious agents remains a substantial hazard for emergency medical services (EMS (emergency medical services)) providers. Such exposure can occur during resuscitation or routine transportation of patients.

Recommendation

(Strong recommendation, based on strong evidence)

EMS providers should wear appropriate respirators when attending to people with suspected or confirmed respiratory TB (tuberculosis) disease. Refer to section "Transport of patients with suspected or confirmed active respiratory TB (tuberculosis)."

Remote and Isolated Health Care Settings

In remote and isolated communities there are many challenges to TB (tuberculosis) infection prevention and control. Resource limitations may result in difficulties with access to adequate diagnostic facilities for bacteriologic examinations and chest radiography. In some remote and isolated First Nations and Inuit communities, the average TB (tuberculosis) incidence rates are high but vary considerably among communities [57]. Refer to Chapter 14, Tuberculosis Prevention and Care in First Nations, Inuit and Métis Peoples.

Respiratory TB (tuberculosis) disease should be ruled out for anyone presenting with unexplained cough for more than 2 weeks with or without fever, unexplained weight loss, hemoptysis, loss of appetite and night sweats. This requires a chest radiograph and analysis of three sputum smears for AFB (acid-fast bacteria). The most important measure for infection prevention and control is a high index of suspicion in members of at-risk populations (refer to section "Identification of patients with active respiratory TB (tuberculosis) within hospitals") with rapid use of diagnostic procedures (including sputum examinations and chest radiography) and early initiation of therapy. If chest radiography is difficult to organize because patients must fly out of the community, then sending sputum samples for AFB (acid-fast bacteria) smear and TB (tuberculosis) culture may be a more rapid way to make a diagnosis.

Recommendations

(Strong recommendations, based on moderate evidence)

- In high-prevalence areas where primary care nurses may be required to collect sputum samples for examination for AFB (acid-fast bacteria), they should wear a respirator and separate themselves from the area where the person is providing the sputum specimen.
- Health care facilities that care for at-risk populations should have access to resources that will facilitate implementation of essential administrative, environmental and personal protective controls.
- Refer to Table 4 for further infection prevention and control recommendations for this setting.

Where resources remain limited because of lack of the infrastructure needed to implement necessary infection prevention and control measures, strategies used in low-resource countries could be implemented: [58]

- Schedule visits from people with suspected or confirmed respiratory TB (tuberculosis) disease at the end of the day or after regular hours.
- If patients needing medical attention cannot be transferred to a facility with an AIIR (airborne infection isolation room), cohort smear- positive TB (tuberculosis) patients, provided they are receiving treatment and there is no suspicion of drug resistance (or the prevalence of drug-resistance is known to be very low) [26].
- Establish effective out-patient services with community-based treatment programs (in homes) to complete treatment started in the hospital, especially where AIIR (airborne infection isolation room)s are unavailable [58].
- When outdoor temperature permits, use natural ventilation to assist in reducing the risk of transmission of airborne pathogens. The World Health Organization has produced evidence-based guidelines on natural ventilation with minimal hourly ventilation rates [59].

Home Care Settings

Home care is delivered to patients who reside in their home or a community care residence. *M. tuberculosis* transmission to HCW (healthcare workers)s who work in home-based health care settings has been documented with recommendations developed to prevent transmission [7]. The room in the home where the patient spends considerable amounts of time should be well ventilated [16].

Recommendations

(Conditional recommendations, based on very weak evidence)

- Home care agencies in consultation with public health authorities should develop a system for screening at-risk clients for signs of respiratory TB (tuberculosis) disease before and during visits, thus facilitating earlier diagnosis and use of appropriate infection prevention and control measures.
- HCW (healthcare workers)s caring for clients with respiratory TB (tuberculosis) disease at home should wear a respirator (refer to section "Respirators and masks").
- HCW (healthcare workers)s should not perform cough-inducing or aerosol-generating medical procedures on clients with suspected or confirmed infectious TB (tuberculosis) disease, because recommended infection prevention and control measures will probably not be in place in the home [7].
- Refer to Table 4 for further infection prevention and control recommendations for this setting.
- Refer to Figure 2 on home isolation and Chapter 5, Treatment of Tuberculosis Disease.

Prevention of Transmission of *M. Tuberculosis* Within Residential and Community Care Settings

While guidance is available on preventing *M. tuberculosis* transmission in health care settings, less has been written about prevention in community care settings, even though the incidence of LTBI (latent TB infection) and active TB (tuberculosis) disease in these settings exceeds that in the general population who are not receiving care [60].

Adult Day Care Centres

For the purposes of these guidelines, adult day care facilities include basic or specialized day care centres for adults or other special adult populations requiring care. Adult day care services often include group programs designed to meet the social and health needs of functionally and/or cognitively impaired adults. Examples of clients include individuals with Alzheimer's disease, developmental disabilities, traumatic brain injury, mental illness, vision and hearing impairments [37]. Refer to Table 4 for screening recommendations for clients and employees. These recommendations apply only to clients who expect to use these services for 4 or more hours per week or for 150 or more hours per year.

Homeless Shelters and Drop-in Centres

Recent extended outbreaks of *M. tuberculosis* in homeless and under-housed individuals in Canada and the United States highlight the risk of ongoing transmission within this population [61] [62]. Overcrowding increases transmission risk, as does failure to recognize signs and symptoms of respiratory TB (tuberculosis) disease and inability to take immediate steps to prevent transmission. An upsurge in foreign-born homeless people in Canada could present an increased risk of drug-resistant strains being introduced into the homeless shelter system [6]. Employees and regular volunteers of shelters are at increased risk of becoming infected with TB (tuberculosis) because of frequent exposure to undiagnosed cases, compounded by inadequate ventilation. Screening for LTBI (latent TB infection) among the homeless can be labour intensive and complicated, and adherence to therapy for LTBI (latent TB

infection) is often low in this population. Active case finding can also be challenging, as a large proportion of homeless people may have chronic cough and other symptoms that can imitate those of TB (tuberculosis). Furthermore, following up on contacts of active cases can be extremely difficult.

Primary prevention of TB (tuberculosis) through improved environmental controls is perhaps the most important control strategy. This includes cleaning, repair and upgrading of air filter units as well as adding in-duct and upper-air UVGI (ultraviolet germicidal irradiation), which will help reduce the risk of TB (tuberculosis) transmission [63]. Opening windows to improve fresh air ventilation can also result in a dramatic decrease in *M. tuberculosis* transmission, especially in shelters with inadequate ventilation [64]. However, this is not feasible for most of the year in Canada because of cold temperatures. Guidelines to assist shelter operators and staff in reducing the risk of *M. tuberculosis* transmission in homeless shelters have been published [64] [65].

Recommendations

(Conditional recommendations, based on very weak evidence)

- With support from local public health authorities, homeless shelters should develop and implement a TB (tuberculosis) management program that provides education to staff, volunteers and clients.
- Refer to Table 4 for further infection prevention and control recommendations for this setting.

Addiction Treatment Centres

A high prevalence of positive TST (tuberculin skin testing) concurrent with increasing duration of injection drug use has been documented in this population. In addition, drug users have also been shown to have an increased risk of progression from LTBI (latent TB infection) to active TB (tuberculosis) disease [10]. The benefit of TST (tuberculin skin testing) screening for this high-risk population in terms of follow-up medical evaluation and adherence to therapy has been low [10]. Incentives have been shown to be a consistent and effective strategy for increasing participation in TB (tuberculosis) screening as well as educational activities for this population [10] [66]. Refer to Table 4 for further recommendations for this setting.

In populations known to have poor rates of return for TST (tuberculin skin testing) reading (e.g. homeless individuals and intravenous drug users), use of IGRAs can help achieve a higher rate of test completion and follow-up, although completion of LTBI (latent TB infection) treatment may still be challenging.

Prevention of Transmission of *M. Tuberculosis* Within Correctional Facilities

The following is based in part on the Correctional Service Canada (CSC (Correctional Service Canada)) guidelines for TB (tuberculosis) prevention and control in institutions in which inmates are sentenced to 2 years or longer [67]. At the time of publication of this Standard, the CSC (Correctional Service Canada) guidelines were under revision. An additional resource is the guideline published by the CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention) on the prevention and control of TB (tuberculosis) in US correctional and detention facilities [68]. It should be noted that the recommendations below were developed mainly for federal facilities, as TB (tuberculosis) prevention and control activities and capacity vary across Canada for provincial/territorial correctional facilities. The latter facilities generally have more inmates, most of whom have shorter stays than inmates in federal facilities. The shorter duration of incarceration in provincial/territorial facilities, make it more difficult to implement recommendations developed for federal facilities.

The risk of TB (tuberculosis) transmission is higher in correctional facilities as a result of several factors:

1. The prevalence of LTBI (latent TB infection) among correctional facility inmates is higher than in the average Canadian population.
2. The risk of reactivation of LTBI (latent TB infection) to active TB (tuberculosis) disease is increased because of the higher prevalence of HIV (human immunodeficiency virus) infection, other comorbidities, previous or current cigarette smoking, and alcohol and injection drug abuse in this population.
3. Diagnosis may be delayed because of poor use of medical services.
4. Ventilation is often inadequate because of recirculation of air and a lack of open windows. This is more common in older prisons that were built to achieve security, not airborne infection control.
5. The density of inmates may be high (crowding).
6. Transfer of inmates within and between facilities may be frequent.

TB (tuberculosis) Control Program for Correctional Facilities

It is recommended that the first step of a TB (tuberculosis) management program in a correctional facility should be to perform an institutional risk assessment in order to decrease the risk of inmate and staff exposure to and acquisition of *M. tuberculosis*. This risk assessment is based on the baseline TB (tuberculosis) status of inmates and staff and an annual review of active respiratory TB (tuberculosis) cases diagnosed among inmates (and, if any, among staff). This involves inquiries into the medical and TB (tuberculosis) history as well as risk factors and symptoms. Past TB (tuberculosis)-related history should be collected, if necessary, by accessing a comprehensive electronic medical database. The history should be reviewed carefully, including results of previous TST (tuberculin skin testing)s and any chest radiography, as should prior treatment of LTBI (latent TB infection) or active TB (tuberculosis) disease. Incomplete treatment should prompt a thorough evaluation of the possibility of active TB (tuberculosis) disease by means of chest radiography, medical evaluation and sputum analysis for AFB (acid-fast bacteria) smears and cultures. Active case finding by symptom check is recommended for inmates on admission (baseline) and annually thereafter. At all other times a high index of suspicion should be maintained in order to minimize delays in the diagnosis of active respiratory TB (tuberculosis). Suspicion should be particularly high if the inmate has a prior history of TB (tuberculosis), even if treatment was judged to have been adequate, since actual adherence to treatment may have been suboptimal, leading to increased risk of relapse.

AIIR (airborne infection isolation room)s exist across Canada in CSC (Correctional Service Canada) facilities with at least one per geographic/administrative region. The direction of air flow should be into the room, and the air should then be exhausted outdoors. This should be verified when the room is occupied. For treatment of LTBI (latent TB infection) in inmates and staff, refer to Chapter 6, Treatment of Latent Tuberculosis Infection.

Recommendations

(Strong recommendations, based on strong evidence)

- Inmates who are suspected of having respiratory TB (tuberculosis) disease should be placed immediately in an AIIR (airborne infection isolation room) until TB (tuberculosis) is ruled out or they have received sufficient treatment and are deemed no longer infectious (Refer to Figure 1).
- Inmates and staff who are exposed to people with respiratory TB (tuberculosis) disease should be investigated in close collaboration with local public health authorities using the principles outlined in Chapter 12, Contact Follow-up and Outbreak Management in Tuberculosis Control.
- Refer to Table 4 for further infection prevention and control recommendations for this setting.
- If an inmate is discharged while still being treated for active TB (tuberculosis) disease, follow-up should be arranged directly with local public health authorities, so that supervised treatment is not interrupted, even for a day.

Table 4. Summary of recommendations for TB (tuberculosis) infection prevention and control measures in non-hospital settings

For the purposes of this table, "people with infectious TB (tuberculosis)" refers to people with suspected or confirmed respiratory TB (tuberculosis) disease unless otherwise indicated.

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]
Long-term care (homes for the aged, nursing homes, chronic care facilities, hospices, retirement homes, designated assisted living centres and any other collective living centre)	Facility risk assessment by retrospective review of all TB (tuberculosis) cases in preceding 5 years and all available TST (tuberculin skin testing) results for staff and volunteers. This should inform the decision to routinely screen residents. Educate staff about TB (tuberculosis) symptoms, risk factors and infection prevention and control measures [C]. People with infectious TB (tuberculosis) should be transported as soon as possible to an appropriate medical facility and should not return to the setting until they are no longer infectious.	CTS (Canadian Thoracic Society): 2 ACH (air changes per hour) CSA: 4 ACH (air changes per hour) CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention): NR (no recommendation for ACH) FGI/ASHRAE: 2-6 ACH (air changes per hour)	Respirators for HCW (healthcare workers)s in contact with people with infectious TB (tuberculosis) [D]. Mask for people with infectious TB (tuberculosis) if not in airborne infection isolation room (AIIR (airborne infection isolation room)) and during transport.	**Employees/volunteers [E]:** Baseline screening upon hire or placement using two-step TST (tuberculin skin testing) [F]. Annual TST (tuberculin skin testing) unless conversion rate is shown to be ≤0.5% [G]. **Residents/clients:** Baseline posterior-anterior and lateral chest radiography on admission for people >65 years old from identified populations [H]. Baseline two-step TST (tuberculin skin testing) upon admission for identified population £65 years old [F]. Annual TST (tuberculin skin testing) not necessary. Facility risk assessment/local epidemiology should inform decision [I].

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]
Ambulatory care and outpatient clinics Refer to Table 2 for ACH (air changes per hour) recommendations for AIIR (airborne infection isolation room)	Signage at entry requesting use of surgical mask by people with respiratory symptoms that suggest infection. High index of suspicion if signs and symptoms of active TB (tuberculosis) disease. Schedule visit by people with infectious TB (tuberculosis) for end of day.	CTS (Canadian Thoracic Society): 2 ACH (air changes per hour) CSA: 6-9 ACH (air changes per hour) CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention): NR (no recommendation for ACH) FGI/ASHRAE: 6 ACH (air changes per hour)	Respirators for HCW (healthcare workers) in contact with people with infectious TB (tuberculosis) [D]. Mask for people with infectious TB (tuberculosis) if not in AIIR (airborne infection isolation room) or during transport.	**Employees/volunteers [E]:** Baseline screening upon hire or placement using two-step TST (tuberculin skin testing) [F]. Annual TST (tuberculin skin testing) not necessary. **Patients**: Refer to Chapter 13, Tuberculosis Surveillance and Screening in High-risk Populations, for information on which individuals should be screened.
Clinic or nursing station etc. in remote and isolated settings or communities Refer to Table 2 for ACH (air changes per hour) recommendations for AIIR (airborne infection isolation room)	Schedule visits for people with infectious TB (tuberculosis) at the end of the day or after hours. Educate staff on TB (tuberculosis) symptoms, risk factors and infection control measures. Community-based treatment program (refer Figure 2 on home isolation). Patient with infectious TB (tuberculosis) who cannot be medically managed at home should be transferred	CTS (Canadian Thoracic Society): 2 ACH (air changes per hour) and/or UVGI (ultraviolet germicidal irradiation) to supplement CSA: 6-9 ACH (air changes per hour) CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention):	Respirators for HCW (healthcare workers)s in contact with people with infectious TB (tuberculosis) [D]. Mask for people with infectious TB (tuberculosis) if outside the home.	**Employees/volunteers [E]:** Baseline screening upon hire or placement using two-step TST (tuberculin skin testing) [F]. Annual TST (tuberculin skin testing) if previously negative and people with infectious TB (tuberculosis) are being seen in the facility. Otherwise, annual TST (tuberculin skin testing) is not necessary [G].

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]
	to an appropriate hospital as soon as possible.	NR (no recommendation for ACH)		
		FGI/ASHRAE: 6 ACH (air changes per hour) Natural ventilation where no mechanical ventilation exists and weather permits.		**Patients**: Refer to Chapter 13, Tuberculosis Surveillance and Screening in High-Risk Populations, regarding which individuals should be screened upon admission.
Home care	Educate staff on TB (tuberculosis) symptoms, risk factors and infection prevention and control measures. Refer to Figure 2 for home isolation recommendation.	ACH (air changes per hour): NA (not applicable) People with infectious TB (tuberculosis) should not share common airspace with non-household members. Use of natural ventilation when weather permits.	Respirators for HCW (healthcare workers)s in contact with people with infectious TB (tuberculosis) [D]. Mask for people with infectious TB (tuberculosis) if leaving home for necessary appointment.	**Employees/volunteers [E]:** Baseline screening upon hire or placement using two-step TST (tuberculin skin testing) [F]. Annual TST (tuberculin skin testing) if employee's results were previously negative and agency provides care for people with infectious TB (tuberculosis). Otherwise, annual TST (tuberculin skin testing) is not necessary [G]. **Clients**: NA (not applicable)
Adult day care centres	Refer to recommendations for long-term care (LTC (long-term care)) above.	NR (no recommendation for ACH)	Refer LTC (long-term care) above.	Refer to recommendations for LTC (long-term care) above.

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]
Homeless shelters **Drop-in centres** **Addiction treatment centres**	TB (tuberculosis) management program. Educate staff on TB (tuberculosis) symptoms, risk factors and infection prevention and control measures. Head-to-foot bed arrangement. Incentives and enablers may be considered to encourage resident screening for LTBI (latent TB infection). People with infectious TB (tuberculosis) should be immediately placed in a separate room, transported to an appropriate health care facility and returned only when they are no longer infectious.	CTS (Canadian Thoracic Society): 6 or 0.708 m^3/min/person [J]. CSA: NR (no recommendation for ACH) CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention): 25 cubic feet of outside air/minute/person FGI/ASHRAE: NR (no recommendation for ACH) Maintenance and upgrade of HVAC (heating, ventilation and air conditioning) filter units as required. UVGI (ultraviolet germicidal irradiation) [L] Use of natural ventilation where no mechanical ventilation exists	Respirators for HCW (healthcare workers)s performing medical assessment of people with infectious TB (tuberculosis) prior to transfer for medical care [D]. Mask for people with infectious TB (tuberculosis) pending and during transport to a health care facility.	**Employees/volunteers [E]:** Baseline screening upon hire or placement using two-step TST (tuberculin skin testing) [F]. Annual TST (tuberculin skin testing) if negative [G].

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]
		and weather permitting.		**Clients**: Refer to Chapter 13, Tuberculosis Surveillance and Screening in High-risk Populations, for information on which individuals should be screened. In outbreaks consider outbreak case finding.
Correctional facilities	Airborne precautions (refer to Figure 1 legend) for people with infectious TB (tuberculosis) until deemed no longer infectious. Supervised therapy for people with infectious TB (tuberculosis). Educate inmates on importance of completing therapy and on precautions. High index of suspicion for active respiratory TB (tuberculosis). If possible, separate housing of symptomatic new inmates until screened for respiratory TB (tuberculosis) disease. Health teaching for people with respiratory TB (tuberculosis) disease to increase isolation and treatment adherence.	General inmates areas: CTS (Canadian Thoracic Society): 2 ACH (air changes per hour) CSA: NR (no recommendation for ACH) CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention): 6-12 ACH (air changes per hour) FGI/ASHRAE: NR (no recommendation for ACH) AIIR (airborne infection isolation room) : Refer to Table 2	Respirators for HCW (healthcare workers)s and prison staff in contact with people with infectious TB (tuberculosis) [D]. Mask for people with infectious TB (tuberculosis) if not in AIIR (airborne infection isolation room) or during transport.	**Employees/volunteers:** Baseline screening upon hire or placement using two-step TST (tuberculin skin testing) [E]. Baseline assessment for signs, symptoms and risk factors for TB (tuberculosis). Annual TST (tuberculin skin testing) if negative [G]. Annual assessment for signs and symptoms of active TB (tuberculosis) disease.

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]
		for ACH (air changes per hour) recommendations for non-isolation rooms and AIIR (airborne infection isolation room) in the infirmary. HEPA (high-efficiency particulate air) filtration [K]. UVGI (ultraviolet germicidal irradiation) [K]		**Inmates**: If >1 year stay, baseline screening at admission using two-step TST (tuberculin skin testing) [F]. Returning inmates receive a single-step TST (tuberculin skin testing). Annual TST (tuberculin skin testing) thereafter (if TST (tuberculin skin testing) negative) and assessment of risk factors for active TB (tuberculosis) disease [G]. Annual assessment of signs and symptoms for inmates with positive TST (tuberculin skin testing) or history of TB (tuberculosis), and medical examination for inmates with symptoms of active TB (tuberculosis) disease. If <1 year stay, assess for symptoms and signs of TB (tuberculosis), past history of TB (tuberculosis) and known immunosuppression at admission. If any of these is present, chest radiography and medical evaluation should be done.

Table 4. Legend

AIIR (airborne infection isolation room)
airborne infection isolation room

ACH (air changes per hour)

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection controls	Screening and surveillance [B]

air changes per hour

NA (not applicable)
not applicable

NR (no recommendation for ACH)
no recommendation for ACH (air changes per hour)

A
Recommendations for ACH (air changes per hour) are from the Canadian Thoracic Society (CTS (Canadian Thoracic Society)), [15] Canadian Standards Association (CSA), [36] US Centers for Disease Control and Prevention (CDC (Centers for Disease Control and Prevention) (Centers for Disease Control and Prevention)), [7] [68] [69] and Facilities Guidelines Institute/American Society of Heating Refrigeration and Air-conditioning Engineers (FGI/ASHRAE) [37]. Consult the reference document for complete ACH (air changes per hour) recommendations prior to implementing.

B
If an exposure episode occurs in any of the settings in this table, post-exposure screening should be conducted. Refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, and Chapter 12, Contact Follow-up and Outbreak Management in Tuberculosis Control, for information on post-exposure TST (tuberculin skin testing) protocol and contact investigation respectively. It is recommended that the investigation be done in close collaboration with the local public health/TB (tuberculosis) control authorities.

C
Various facility operators can contact their regional public health office for resources that can be used to educate staff on control measures for TB (tuberculosis). Some educative materials can be found at the Curry International Tuberculosis Center, About TB (tuberculosis) External Link, website.

D
Respirators should be NIOSH (National Institute for Occupational Safety and Health) (National Institute for Occupational Safety and Health)-certified and filter at least 95% of particles of diameter 0.3 micron or larger with less than a 10% leak (e.g. N95 respirators).

E
A regular volunteer may be defined as one who expects to work 150 or more hours during the coming year, meaning approximately a half day per week. Volunteers expecting to work less than 150 hours during the coming year should be tested if they are known to belong to an at-risk population group listed in the section "Identification of patients with active respiratory TB (tuberculosis) within hospitals" in this chapter. If volunteers have a history of active TB (tuberculosis), or a history of a chest x-ray suggesting possible past TB (tuberculosis), or have symptoms consistent with active TB (tuberculosis) (fever, cough for more than 2 weeks with or without fever, unexplained weight loss, hemoptysis, loss of appetite and night sweats), they should be referred for full medical evaluation rather than simply a TST (tuberculin skin testing).

F
A one-step TST (tuberculin skin testing) may be given to people who meet the following criteria: (1) documented results of a prior two-step TST (tuberculin skin testing) with a result of <10 mm at any time in the past, (2) documented, single negative TST (tuberculin skin testing) result within the past 12 months or (3) two or more documented negative TST (tuberculin skin testing) results at any time, the most recent one being less than 12 months ago. If prior results exist, these should be transcribed into the person's health record. Staff with a positive TST (tuberculin skin testing) at baseline screening do not need to be re-tested but should be assessed by a physician knowledgeable in the treatment of LTBI (latent TB infection). Such staff should also be instructed to promptly report any symptoms suggesting TB (tuberculosis) disease, such as cough of more than 2 weeks' duration with or without fever, night sweats or weight loss.

G

Facility/setting	Administrative controls	Environmental controls [A]	Personal respiratory protection	Screening and surveillance [B]
Refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection, for TST (tuberculin skin testing) protocol. If a HCW (healthcare workers) or staff member has an exposure episode following which he/she is tested as a contact of a person with confirmed active respiratory TB (tuberculosis) and found negative, the HCW (healthcare workers) or staff's next annual test should be 12 months after the negative result. All TST (tuberculin skin testing) conversions should be reported to the local public health authority, as this may be indicative of TB (tuberculosis) transmission within a facility. HCW (healthcare workers) or staff with a positive TST (tuberculin skin testing) on annual screening should be assessed by a physician knowledgeable in the treatment of LTBI (latent TB infection). They should also be instructed to promptly report any symptoms suggesting TB (tuberculosis) disease (as per jurisdictional requirements), such as cough of more than 2 weeks' duration with or without fever, night sweats or weight loss.				

H

Applies to people known to belong to an at-risk population group listed in the section "Identification of patients with active respiratory TB (tuberculosis) within hospitals" in this chapter.

I

The decision to routinely screen (annually or otherwise) should be based on past incidence of active TB (tuberculosis) in the resident population served by the institution. For example, were there any active TB (tuberculosis) cases within the past 10 years?

J

Natural ventilation recommended for areas frequented by clients, use whichever is higher.

K

Adjunctive use of HEPA (high-efficiency particulate air) filtration units and UVGI (ultraviolet germicidal irradiation) can be considered in AIIR (airborne infection isolation room)s, especially in older correctional facilities where it is not practical or feasible to achieve the recommended levels of natural ventilation.

L

Shelters that cannot afford upgrades to their HVAC (heating, ventilation and air conditioning) systems to provide recommended air exchange rates should consider appropriately placed UVGI (ultraviolet germicidal irradiation) systems, as these can achieve equivalent air exchanges at a fraction of the cost [64].

    3.2 Patient Factors
    3.3 Pathogen Factors
    3.4 Environmental Factors
    3.5 Measures to Prevent Transmission
4. References

Key Messages/Points

- Infection with *Mycobacterium tuberculosis* is acquired by inhalation of bacilli-containing droplet nuclei small enough (diameter 1-5 microns) to reach the alveoli.
- Through innate immune mechanisms, alveolar macrophages eradicate the bacteria in some individuals; in others, the bacteria are able to replicate and establish tuberculosis (TB) infection. Bacterial factors and host genetic factors that promote or limit acquisition of infection are not well understood.
- After infection with *M. tuberculosis*, early primary TB (tuberculosis) disease develops in 5% of people unless they first receive treatment for latent infection. Rapid progression to primary active TB (tuberculosis) is most frequent in infants and young children, and in people with immune compromise.
- In another 5% of infected people there is later development of reactivation TB (tuberculosis) in the absence of treatment for latent TB (tuberculosis) infection (LTBI (latent TB infection)). Risks are much higher for people with immune compromise, notably HIV infection.
- In the remaining 90% progression to active disease never occurs.
- Intact cell-mediated immunity (CMI (cell-mediated immunity)) is required to control and contain *M. tuberculosis* infection. Beyond evident clinical and radiographic risk

factors, it is impossible to predict which infected people will ultimately develop active TB (tuberculosis).

- Transmission of *M. tuberculosis* occurs, with very few exceptions, via droplet nuclei, which can then be inhaled by those who are exposed. For this reason, only those with active pulmonary and/or laryngeal TB (tuberculosis) are likely to be contagious.
- The probability of transmission increases with the following:
  - bacterial burden (smear positivity), cavitary and upper lung zone disease, and laryngeal disease;
  - amount and severity of cough in the source case;
  - duration of exposure;
  - proximity to the source case;
  - crowding and poorer room ventilation;
  - delays in diagnosis and/or effective treatment.
- The most effective way to reduce transmission is to diagnose and treat patients with active TB (tuberculosis) disease as soon as possible.

Pathogenesis

The pathogenesis and transmission of TB (tuberculosis) are inter-related. *M. tuberculosis* is almost exclusively a human pathogen. How it interacts with the human host determines its survival. From the perspective of the bacterium a successful host-pathogen interaction is one that results in pathogen transmission. Initial infection is usually self-limited and followed by a variable period of latency, which ultimately, in a proportion of those infected, results in infectious pulmonary TB (tuberculosis). Transmission from a case of infectious pulmonary TB (tuberculosis) is by the airborne route in minute droplets of moisture that become increasingly reduced by evaporation, creating "droplet nuclei" [1].

Evolution of Initial Infection and Host Response

At the time of initial infection, the distribution of inhaled droplet nuclei in the lung is determined by the pattern of regional ventilation. It thus tends to follow the most direct path to the periphery and to favour the middle and lower lung zones, which receive most of the ventilation [2]. In immunocompetent hosts, it is theorized that alveolar macrophages ingest the *M. tuberculosis* organisms and may or may not destroy them, depending on the degree to which phagocytosing cells are nonspecifically activated, on host genetic factors

and on resistance mechanisms in the bacteria [3]. If bacteria are successfully cleared, then test results will remain negative on the tuberculin skin test (TST (tuberculin skin test)) or interferon-gamma release assay (IGRA (interferon-gamma release assay)).

When innate macrophage microbicidal activity is inadequate to destroy the initial few bacteria of the droplet nucleus they replicate logarithmically, doubling every 24 hours until the macrophage bursts to release the bacterial progenyFootnote 3. New macrophages attracted to the site engulf these bacilli, and the cycle continues. The bacilli may spread from the initial lesion via the lymphatic and/or circulatory systems to other parts of the body. After a period lasting from 3 to 8 weeks the host develops specific immunity (cell-mediated immunity [CMI] and delayed-type hypersensitivity [DTH]) to the bacilli, and individuals typically show positive results on the TST or IGRA. The resulting M. tuberculosis-specific lymphocytes migrate to the site of infection, surrounding and activating the macrophages there. As the cellular infiltration continues, the centre of the cell mass, or granuloma, becomes caseous and necrotic. Radiographically demonstrable fibrocalcific residua of the initial infection include a Ghon focus (a calcified granuloma in the lung) alone or in combination with a calcified granulomatous focus in a draining lymph node (Ghon complex)Footnote 4 Footnote 5. Infection and immune conversion are usually asymptomatic; any symptoms that do occur are self-limited. In a small proportion of those infected, erythema nodosum (a cutaneous immunologic response to an extracutaneous TB infection) or phlyctenular conjunctivitis (a hypersensitivity reaction) may develop.

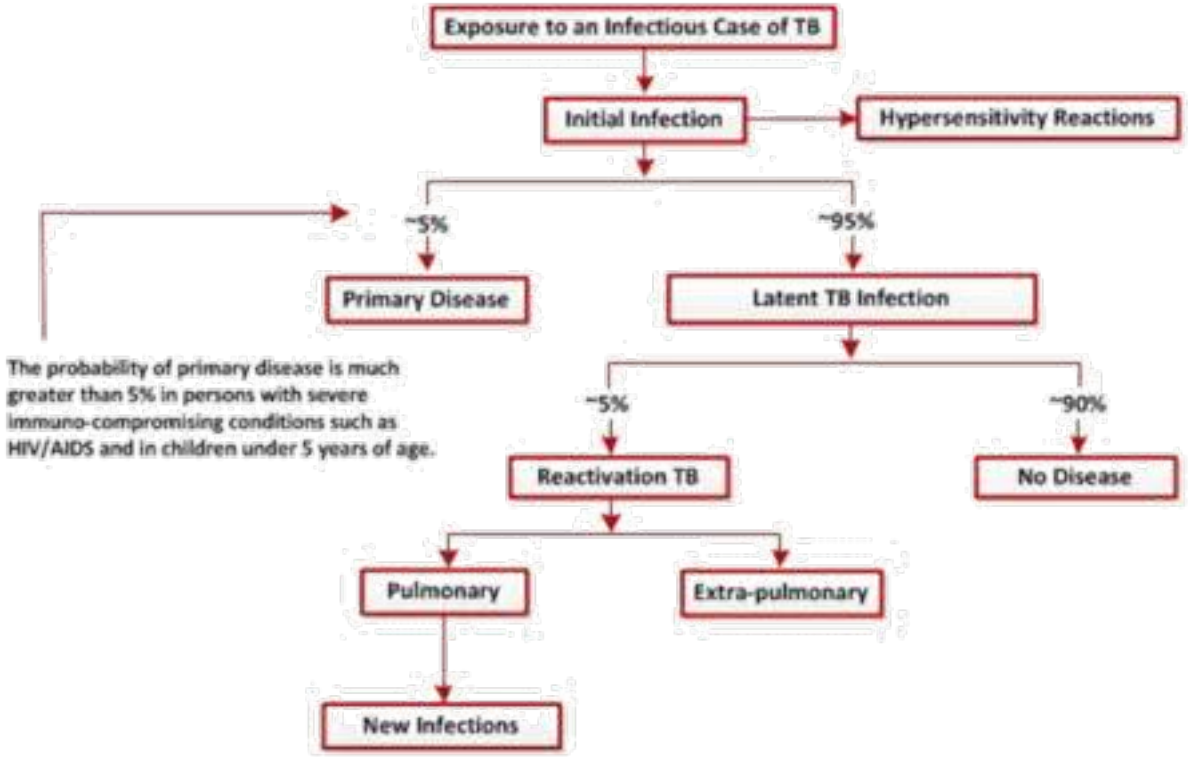
Early Disease Progression (Primary TB (tuberculosis))

A proportion of those who are recently infected are unable to contain the infection despite the stimulation of CMI (cell-mediated immunity) and DTH, and there is progression to disease in a matter of months. Such early disease progression is a function of age and immunologic response, disease being especially likely to occur in young children and the immunocompromised. A progressive Ghon focus, disseminated (miliary) disease and central nervous system disease may occur as early as 2 to 6 months after infection in infants and the severely immunocompromised [6] [7]. Uncomplicated and asymptomatic lymph node disease (hilar or mediastinal lymphadenopathy without airway involvement) may also occur in the first 2-6 months of infection, although there is debate about whether this should be called active disease (refer to Chapter 9, Pediatric Tuberculosis) [6] [8].

At 4-12 months after infection, early disease manifestations include complicated lymph node disease (airway compression, expansile caseating pneumonia, infiltration of adjacent anatomic structures), pleural disease (most commonly a lymphocyte-predominant exudative effusion) and peripheral lymphadenitis (usually in the neck) [6]. In immunocompetent children and adolescents early disease is more likely to manifest as intrathoracic adenopathy and in adults as a unilateral pleural effusion. In severely immunocompromised people of any age (e.g. those with advanced HIV or AIDS), early disease may manifest as intrathoracic adenopathy [9] [10]. Rarely, in newly infected people who are 10 years of age or older (pubertal) adult-type pulmonary disease (refer to Figure 1) or other types of extrapulmonary TB (tuberculosis) (for example bone and joint TB (tuberculosis)) may develop within the first 24 months of infection [11].

While early disease progression may or may not result from lympho-hematogenous spread, late disease progression (refer to Figure 1) is almost always the result of the lympho-hematogenous spread of bacilli. Recent infection with early disease progression probably accounts for many cases of TB (tuberculosis) in recently arrived immigrants [12]. For purposes of disease reporting, everyone with a diagnosis of TB (tuberculosis) made within 18-24 months of infection is considered to have "primary" disease (on balance about 5% of those infected). Those newly infected people in whom TB (tuberculosis) does not develop within this period of time will either be left with LTBI (latent TB infection) and will never experience disease (on balance about 90% of those infected) or, after a variable period of latency, they will develop late disease progression (on balance about 5% of those infected, refer to Figure 1).

Figure 1. The Pathogenesis of Tuberculosis in the Infected Host
(Adapted from the 6th Edition of the Canadian TB (tuberculosis) Standards)



▶ Text Equivalent - Figure 1

Latent Tuberculosis Infection (LTBI (latent TB infection))

In the classical concept of LTBI (latent TB infection), *M. tuberculosis* bacteria are believed to survive for years in Ghon foci and complexes and in the small granulomas or solid caseous material of lympho-hematogenously seeded foci. Presumably, local conditions, an intact CMI (cell-mediated immunity) or the presence of inhibitors result in conditions unfavourable to replication. Recent mapping of the complete genome sequence of the bacterium demonstrates that the organism has the potential to synthesize enzymes involved in anaerobic metabolism [13]. Although rapid death and autolysis occur after abrupt depletion of oxygen, the organism can shift into a state of dormancy if allowed to settle through gradual reductions in oxygen tension [14] [15]. Therefore, although *M. tuberculosis* thrives in an aerobic environment, it possesses the genetic and biochemical capability of anaerobic survival and can persist experimentally in oxygen-depleted media. Tubercle formation, with its oxygen-depleted environment, is a defining characteristic of TB (tuberculosis). LTBI (latent TB infection) is usually identified by a positive TST (tuberculin skin test) or IGRA (interferon-gamma release assay) in the absence of active disease (refer to Chapter 4, Diagnosis of Latent Tuberculosis Infection).

More recently LTBI (latent TB infection) and active TB (tuberculosis) have been considered as two ends of a spectrum of states ranging from asymptomatic infection to overt disease [16] [17]. In this more nuanced concept, patients whose LTBI (latent TB infection) progresses to overt disease may pass through a continuum of asymptomatic intermediate states with detectable manifestations indicative of disease [16]. Such asymptomatic disease states frequently remain undiagnosed, and their manifestations and duration are mostly dependent on host immune response. Defining these intermediate states in concrete terms is considered to be important for pragmatic reasons, as they might have an impact upon the performance of TB (tuberculosis) biomarkers or other diagnostic measures and could also present targets for therapeutic interventions [16] [18].

Reinfection

The elegant studies of Ferguson strongly suggest that it takes up to 18 months after the initial infection for CMI to matureFootnote 19. During this period of time a reinfection carries the same risk of disease as the initial infection, perhaps explaining why disease is much more common in newly infected close contacts of smear-positive cases than it is in newly infected close contacts of smear-negative cases - the former having a greater likelihood than the latter of repeated exposure and reinfectionFootnote 20-22. Reinfection of immunocompetent hosts that occurs 18 months or more after the initial infection carries a much lower risk of progression to TB disease, estimated to be 21% of the risk of an initial infection progressing to diseaseFootnote 22. It is not known whether this is because prior infection without development of overt disease is simply a marker for people who are less susceptible to disease development or better able to overcome it once it has developed. Nevertheless, in highly endemic areas the majority of TB cases occurring in those with prior LTBI may be due to reinfection rather than reactivation; in Canada, where repeat exposure is much less common, most active TB reflects reactivation and not reinfectionFootnote 23-25. In the severely immunocompromised host, reinfection and initial infection carry a similarly high risk of disease regardless of when the reinfection occurred (refer to Chapter 6, Treatment of Latent Tuberculosis Infection).

Late Disease Progression (Reactivation TB (tuberculosis))

In Canada, most TB (tuberculosis) is understood to be "reactivation" TB (tuberculosis), i.e. occurring 18-24 months or more after the initial infection. It usually presents as adult-type pulmonary disease (upper lung zone fibrocavitary disease - previously referred to as postprimary TB (tuberculosis) - beginning in small foci that are the result of remote lympho-hematogenous spread), although it may also present as extrapulmonary TB (tuberculosis). As mentioned earlier, adult-type pulmonary TB (tuberculosis) may on occasion be a manifestation of primary TB (tuberculosis) or a reinfection. In any population group, reactivation of LTBI (latent TB infection), leading to reactivation TB (tuberculosis), is much more likely to occur in people who are immunocompromised.

There are a number of theories, most of them speculative, as to why adult-type pulmonary TB (tuberculosis) tends to localize in the upper lung zones. These are described elsewhere [2] [5]. People with a history of untreated or inadequately treated pulmonary TB (tuberculosis) or a "high-risk" lung scar (upper lung zone fibronodular abnormality) on chest radiograph are understood to have a higher bacillary burden than those without such a history/radiograph, and to be at increased risk of reactivation TB (tuberculosis) [26] [27].

From the standpoint of public health and the organism's survival as a species, adult-type pulmonary TB (tuberculosis) is the most important phenotypic expression of the disease. Patients with adult-type pulmonary TB (tuberculosis) are much more likely to show lung cavitation, created when caseous material liquefies (possibly related to hydrolytic enzymes released from inflammatory cells during their destruction and DTH to tuberculin-like proteins) and erodes into the bronchi [28]. Within the unique extracellular environment of cavities, host defences are ineffectual, and bacteria multiply in large numbers. Because cavities are open to, and discharge their contents into, nearby bronchi these same bacteria are directly communicable to the outside air when the patient coughs. Transmission from patients with adult-type pulmonary TB (tuberculosis) is facilitated by the concurrent involvement of both the airways and their contiguous pulmonary blood supply at sites of disease in the lung. This minimizes the respiratory limitation experienced by the patient, extending the life of the host within the community and creating further opportunities for transmission before the patient either seeks medical attention or succumbs [29].

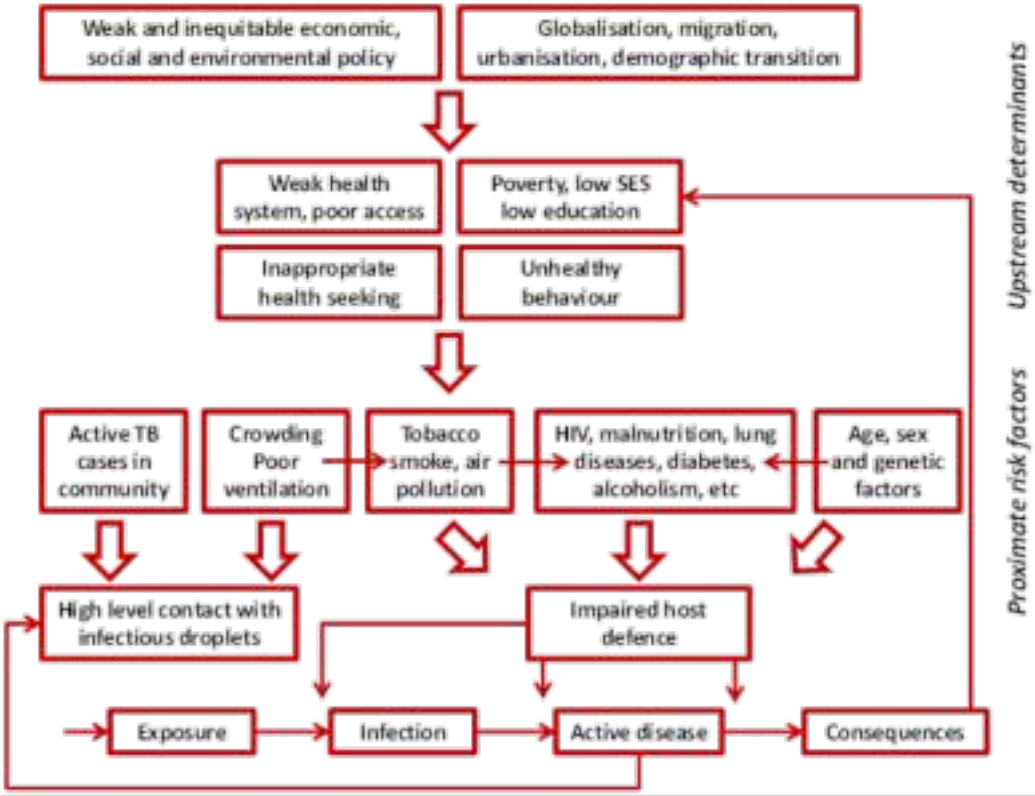
Extrapulmonary TB (tuberculosis)

Outside of the extrapulmonary sites of disease alluded to in the section Early Disease Progression and cases of bone and joint TB, whose timeline from infection to disease in children may be as short as a year, most extrapulmonary TB is reactivation disease. Extrapulmonary TB or combined pulmonary and extrapulmonary TB is more common in those who are severely immunocompromised; in those coinfected with HIV the occurrence of extrapulmonary TB increases as the CD4 count decreases (refer to Chapter 7, Non-respiratory Tuberculosis)Footnot9 Footnote 10.

Risk Factors for Progression from Infection to Disease

The risk of transition from LTBI (latent TB infection) to active TB (tuberculosis), primary or reactivation, is largely dependent on the immune competency of the host. Age and sex appear to directly affect the immunologic response and the risk of disease: morbidity is greater among young children (<5 years of age), especially infants, among young adults, especially females, and among older adults, especially males. In high-burden countries, the population attributable fraction of undernutrition for TB (tuberculosis) is 27% according to the WHO [30]. The seasonality of TB (tuberculosis) (with the highest incidence in spring and early summer) has been attributed to reduced sunlight and vitamin D deficiency during the winter months in some studies but not in others [31-33]. Ethnic differences have been offered as factors determining host immune response, with some support [34], but differences among ethnic groups in all clinical forms of TB (tuberculosis) are probably best explained as phase differences in an epidemic wave [35]. All races initially exposed in an epidemic as a group are equally susceptible, but eventually death and survival outcome select out people who are relatively more resistant. A growing body of evidence suggests that host genetic factors are important in determining susceptibility to TB (tuberculosis) [36-38]. Most important from a clinical perspective are the many medical conditions that are well known to affect host immunologic response and increase the risk of progression from LTBI (latent TB infection) to active TB (tuberculosis) disease. These are reviewed in detail in Chapter 6, Treatment of Latent Tuberculosis Infection. To identify entry points for interventions aimed at addressing TB (tuberculosis) risk factors as well as social determinants, Lönnroth and colleagues developed a framework for proximate risk factors and upstream determinants of TB (tuberculosis) (refer to Figure 2) [39].

Figure 2. Framework for proximate risk factors and upstream determinants of TB (tuberculosis) [39]



▶ Text Equivalent - Figure 2

Transmission [40-43]

M. tuberculosis is communicable from one human to another mainly by the aerosol route and rarely through ingestion or percutaneous inoculation (e.g. through laboratory or hospital accident). Bovine TB (tuberculosis), which in the past was caused by ingestion of milk heavily infected by *M. bovis* that then penetrated the mucosa of the oropharynx or the gastrointestinal tract, has been largely eradicated as a result of the pasteurization of milk and the tuberculin testing of cattle, followed by the slaughter of animals found to be infected.

The reservoir for M. tuberculosis is humans. Other animals, in particular primates, may be infected but are rarely a source of infectionFootnote 40-43. Droplet nuclei, sometimes referred to as "the quanta of contagion", are created by forceful expiratory efforts, such as coughing, sneezing, singing, playing wind instruments and even speaking. Before droplets reach the airspace of a room and have had an opportunity to evaporate down to a "droplet nucleus" their numbers can be reduced by wearing a simple gauze (surgical) mask or covering the mouth and nose during coughing. Certain procedures, for example, bronchoscopy, sputum induction, processing of specimens, autopsy and

even irrigation or other manipulation of tuberculous abscesses, may also produce infectious aerosols. The droplets have an extremely slow settling rate (0.5 mm per second or less), which permits their transport by air currents, duct systems or elevator shafts for significant distances from the source case. Large particles settle quickly and are either not inhaled by contacts or, if inhaled, are trapped in the mucus of the upper airway. If the organism reaches the trachea and bronchi it is usually swept back to the larynx by ciliary action and cough, and then swallowed. For practical purposes, only the droplet nuclei in the size range 1 to 5 microns reach the terminal air spaces or alveoli; each is understood to contain only a few bacteria. In most instances only one such droplet nucleus is believed to be responsible for establishing infection in the host. Bacteria that are lodged on fomites (linen, furniture, books, floors) do not constitute a significant source of infection: most die quickly through the action of drying, heat or sunlightFootnote 5 Footnote 40-43.

The rate of transmission can be measured by the percentage of close contacts (household and non-household) whose TST (tuberculin skin test) or IGRA (interferon-gamma release assay) responses are converted from negative to positive or in whom active TB (tuberculosis) disease develops. The percentage will depend on the number of infectious droplet nuclei per volume of air (infectious particle density) and the length of time that the uninfected individual spends breathing that air. In the past, drug susceptibility patterns and phage typing of *M. tuberculosis* isolates have helped to confirm the transmission between source case and contact. More recently, DNA fingerprinting of *M. tuberculosis* isolates has greatly refined the identification of this relation [44].

Because of the highly variable latency period of *M. tuberculosis* infection it is difficult to precisely document transmission using currently available tools. People found to have positive TST (tuberculin skin test)s and/or IGRA (interferon-gamma release assay)s during contact investigation may have been infected in the past (remotely) rather than by the recent source case of concern, though for contact management and public health purposes these contacts are treated as if recently infected if there is no way to determine the duration of infection. DNA fingerprinting techniques will only detect transmission to the small group of people in whom active disease develops following transmission. If most TB (tuberculosis) disease in a community reflects recent/ongoing transmission, the first priority for public health authorities should be to prevent further

transmission. On the other hand, if most TB (tuberculosis) reflects reactivation of remotely acquired infection, the priority should shift to identification and treatment of people with LTBI (latent TB infection), notably those with risk factors for reactivation.

Patient, Pathogen and Environmental Determinants of Transmission

Several patient, pathogen and environmental factors determine whether transmission occurs, largely by affecting the number of infectious droplet nuclei per volume of air (refer to Table 1). Although the probability of being infected after contact with an infectious source decreases with decreasing duration and decreasing closeness of contact, the absolute number of casual contacts infected may exceed the number of infected close contacts, since the former may far outnumber the latter [45]. DNA fingerprint data have highlighted the limits of contact tracing in settings where there is exposure of a large number of people unknown to source cases and in settings where social connections are tenuous at best [46] [47]. At this point very little is known about what, if any, host determinants influence the acquisition of initial infection after inhalation of a droplet nucleus. Some individuals are able to achieve complete or "sterile" elimination of *M. tuberculosis* bacteria rather than developing latent infection [48]. Observational studies suggest that BCG vaccination in infancy offers some protection against infection with *M. tuberculosis* as detected by an IGRA (interferon-gamma release assay) [49-52].

Table 1. Patient, pathogen and environmental factors affecting transmission

Patient	Pathogen	Environment
Disease type	Strain variability	Indoor/outdoor
Pulmonary Smear-positive/smear-negative Cavitary/non-cavitary on CXR [A] Typical/atypical on CXR Laryngeal		Air circulation/ventilation Sunlight
Extrapulmonary		Proximity to the source case
Symptomatology		Duration of exposure
Delayed diagnosis

Patient	Pathogen	Environment
Treatment		
ACXR = chest radiograph		

Patient Factors

With rare exception (e.g. transmission related to an inadequately sterilized bronchoscope or a needle stick injury), transmission requires that a TB (tuberculosis) patient be able to produce airborne infectious droplets [41-43]. This most often limits the potential for transmission to adolescent or adult patients with adult-type pulmonary TB (tuberculosis). Younger children can on occasion be infectious [53], but as a general rule they have few bacilli in their lesions, often do not produce sputum and rarely have communicable disease [54]. Of patients with TB (tuberculosis) involving the respiratory tract not all are equally efficient at transmission.

1. Sputum smear status

Patients with smear-positive/culture-positive pulmonary TB (tuberculosis) are more infectious than patients with smear-negative/culture-positive pulmonary TB (tuberculosis), and the latter are more infectious than patients with smear-negative/culture-negative pulmonary TB (tuberculosis) (refer to Table 2 for a summary of the epidemiologic studies on the risk of infection in household [close] contacts grouped according to the bacteriologic status of the source cases) [55-62]. Sputum that is smear-positive contains 5,000 or more organisms per millilitre of sputum [57] [58] [63] [64] Patients with smear-positive bronchoalveolar lavage fluid are considered just as infectious as those with smear-positive sputum [65]. Smear-positive induced sputum is for practical purposes considered to indicate the same degree of contagiousness as smear-positive spontaneously expectorated sputum, though there are currently no data that prove this assertion [55]. With the use of molecular epidemiologic tools the relative transmission rate of smear-negative compared with smear-positive patients has been determined to be 0.17-0.22 or roughly one-fifth the likelihood of transmission [66] [67]. In addition to the greater infectivity of smear-positive cases, as mentioned in the section Pathogenesis, the risk of disease after infection from a smear-positive case is greater, by virtue of the higher probability of repeated infection, than it is after infection from a smear-negative case.

Table 2. [A] Risk of infection among household (close) contacts according to bacteriologic status of index case (pulmonary TB (tuberculosis) only)

Ref no.	Year of survey	Location	Contacts		Number and % infected contacts by bacteriologic status of index case						General population % positive PPDB [B]

[C] In this study contacts were considered infected only if tuberculin conversion and/or primary TB (tuberculosis) had been documented.

S = smear, C = culture, PPD = purified protein derivative

2. Disease type on plain chest radiograph

Pulmonary TB (tuberculosis) patients with cavitation on chest radiograph are more infectious than pulmonary TB (tuberculosis) patients without cavitation after bacteriologic findings have been taken into account [68-70]. Pulmonary TB (tuberculosis) patients with "typical" chest radiographic findings (upper lung zone disease, with or without cavitation, and no discernable intrathoracic adenopathy) are more infectious than pulmonary TB (tuberculosis) patients with "atypical" chest radiographic findings (all others) [71].

3. Laryngeal disease

Patients with laryngeal TB (tuberculosis) are more infectious than those with pulmonary TB (tuberculosis) [72]. Most patients with laryngeal TB (tuberculosis) (hoarseness associated with inflammation and ulceration of the vocal cords) have far advanced pulmonary disease upstream from the larynx [73].

4. Symptomatology

In general, normal breathing produces few infectious particles, a bout of coughing or five minutes of speaking in a normal tone produce many more, and a sneeze produces the most [74] [75]. The likelihood that household contacts will be infected increases with the frequency of cough in the source case [60]. When the aerial infectivity of the droplets from smear-positive patients was evaluated by artificially atomizing sputum and exposing guinea pigs to a standard dose, there was marked variability in the infectivity of aerosolized sputum, perhaps explaining the extraordinary heterogeneity of infectiousness among patients with smear-positive pulmonary TB (tuberculosis) [76-78]. Thus, although patients may appear to have an equal number of bacteria in their sputum, the physical and chemical properties of their sputum, as well as their effectiveness as an aerosolizer, may determine whether they produce a large or small number of droplet nuclei. The role of smoking, allergy or coincidental viral upper respiratory tract infection in aerosol formation is unknown [79].

5. Delayed diagnosis

The number of contacts and the duration of exposure of each contact may increase as time to diagnosis increases. The longer the duration of symptoms in the source case the greater the risk of transmission [65].

6. Treatment

Effective treatment (refer to Chapter 5, Treatment of Tuberculosis Disease) appropriate to the drug susceptibility test results rapidly reduces cough frequency and sputum bacillary counts [60] [80]. Even faster than the rate of decrease of the latter is the rate of decrease of bacillary counts in cough-generated aerosol cultures [81]. With treatment those bacteria that continue to be expectorated may be expected to be less metabolically active and/or are inhibited by the drugs, two effects that may decrease the chances of the organism establishing an infection in the host [76] [82]. However, in theory, any residual viable bacteria in respiratory secretions can be transmitted, although the chances of this occurring decrease rapidly with effective treatment [83]. Given the frequency of drug resistance, the determination that treatment is effective in reducing the infectiousness of a given patient should reflect objective clinical, radiographic and/or microbiologic improvement, and not simply time elapsed since treatment initiation.

Pathogen Factors

Data are emerging to suggest that one or more virulence properties of *M. tuberculosis* may affect its ability to be transmitted [84]. For example, one strain may be better suited than another to overcoming the innate resistance of the host. Although drug-resistant strains have shown reduced virulence in animal models [85], clinical evidence of their transmissibility is compelling [86-89], and for practical purposes they should be considered just as transmissible as drug-susceptible strains. Beijing/W strains have been reported to be hypervirulent, but indices of transmission have been found to be no greater in patients with these strains than in those without them [90].

Environmental Factors

Outdoor exposures are very unlikely to result in transmission unless the source and the susceptible person are in talking distance. Bacillary dispersion is immediate, and sunlight rapidly kills any viable bacilli [91] [92]. For practical purposes outdoor exposures are not investigated during a contact tracing exercise.

1. Air circulation and ventilation

Given a defined number of bacteria expelled into the air, the volume of air into which the bacteria are expelled determines the probability that a susceptible individual breathing that air will become infected. A high concentration of viable bacteria in the inhaled air of the contact is favoured by indoor exposure, poor ventilation or recirculation of air, and little sunlight (ultraviolet rays). Ventilation dramatically dilutes the concentration of infectious droplet nuclei (refer to Chapter 15, The Prevention and Control of Tuberculosis Transmission in Health Care and Other Settings, for further information on clearance times).

2. Proximity to the source case

Proximity to the source case is also a determinant of transmission. Related to this is overcrowding: if, as a result of there being many people in a room, an individual is forced into close proximity with an infectious case his or her risk of infection is likely to increase.

3. Duration of exposure

Because of the dilution of infected air and the low concentration of infectious droplet nuclei, the duration of exposure required to ensure that transmission occurs is commonly prolonged (days, months or even years), and yet reports have confirmed that exposures as short as a few minutes may be sufficient to infect a close contact. The latter would appear to be supported by the high proportion of active cases that deny any history of exposure.

Measures to Prevent Transmission

The highest priority should be given to early diagnosis and prompt, effective treatment of the source case together with isolation of the patient when necessary. The insidious development of symptoms in most cases of TB (tuberculosis) commonly results in a delay of weeks or months before the patient presents for diagnosis. At that point, when the patient is often at his or her most infectious, any further delay caused by the physician, nurse or system allows unnecessary transmission to others. Maintaining an appropriate awareness of TB (tuberculosis) among health care providers is thus critical to reducing transmission and initiating early prevention and treatment. Administrative and engineering controls that aim to reduce exposure in health care and other congregate settings complement--but cannot replace--prompt diagnosis and

appropriate therapy. Methods once thought to be important in preventing the transmission of TB (tuberculosis) - disposing of such personal items as cloths or bedding, sterilizing fomites, using caps and gowns, gauze or paper masks, boiling dishes and washing walls - are unnecessary, because they have no bearing on airborne transmission.

Abstract

Background

Because mass gatherings create environments conducive for infectious disease transmission, public health officials may recommend postponing or canceling large gatherings during a moderate or severe pandemic. Despite these recommendations, limited empirical information exists on the frequency and characteristics of mass gathering-related respiratory disease outbreaks occurring in the United States.

Methods

We conducted a systematic literature review to identify articles about mass gathering-related respiratory disease outbreaks occurring in the United States from 2005 to 2014. A standard form was used to abstract information from relevant articles identified from six medical, behavioral and social science literature databases. We also analyzed data from the National Outbreaks Reporting System (NORS), maintained by the Centers for Disease Control and Prevention since 2009, to estimate the frequency of mass gathering-related respiratory disease outbreaks reported to the system.

Results

We identified 21 published articles describing 72 mass gathering-related respiratory disease outbreaks. Of these 72, 40 (56%) were associated with agriculture fairs and Influenza A H3N2v following probable swine exposure, and 25 (35%) with youth summer camps and pandemic Influenza A H1N1. Outbreaks of measles (n = 1) and mumps (n = 2) were linked to the international importation of disease. Between 2009 and 2013, 1,114 outbreaks were reported to NORS, including 96 respiratory disease outbreaks due to Legionella. None of these legionellosis outbreaks was linked to a mass gathering according to available data.

Conclusion

Mass gathering-related respiratory disease outbreaks may be uncommon in the United States, but have been reported from fairs (zoonotic transmission) as well as at camps where participants have close social contact in communal housing. International importation can also be a contributing factor. NORS collects information on certain respiratory diseases and could serve as a platform to monitor mass gathering-related respiratory outbreaks in the future.

Introduction

Mass gatherings create environments conducive to the transmission of infectious disease including pandemic influenza. [1–11]. Some mass gatherings such as outdoor sporting events may involve limited social mixing and are held in settings with ample ventilation. Other mass gatherings, however, can involve significant social mixing over several days such as professional conferences and music festivals [1–4]. Intensely crowded settings can lead to high secondary attack rates even when a circulating pathogen has a relatively low transmission probability [1–4]. Travelers to mass gatherings can not only introduce an infectious disease to a previously unaffected area, but can also amplify transmission at the gathering and further disseminate transmission following their return home. This was recently demonstrated by the propagation of the first wave of the 2009 H1N1 pandemic (pdm09H1N1) following a large Easter holiday gathering in Iztapalapa, Mexico [6]. Similar mass gatherings have been linked to the propagation of the Great Pandemic in 1918 and the Asian Flu Pandemic in 1957 [7–8].

During future influenza pandemics or other public health emergencies in the United States, state and local public health officials will have to consider modifying, postponing, or cancelling mass gatherings. This decision could depend on the severity of the pandemic as well as the timing, duration and size of the event and whether people will be traveling to and from the event from other (affected or not-yet-affected) communities [12]. If the risk of severe disease is low, then other non-pharmaceutical interventions could be recommended to minimize the potential for disease transmission. Despite these recommendations, limited empirical information exists on the frequency and characteristics of mass gathering-related respiratory disease outbreaks in the United States.

To address this gap, we conducted a systemic review of the published literature and analyzed the National Outbreak Reporting System (NORS) database maintained by the United States (U.S.) Centers for Disease Control and Prevention (CDC) since 2009 [13]. The objectives of this project included describing the frequency of mass gathering-related respiratory disease outbreaks occurring in the United States, highlighting the likely causes of these outbreaks, and documenting any patterns or shared characteristics across the identified outbreaks.

Methods

Data collection

Definitions. Mass gatherings can be defined as large events involving more than 1,000 persons in a specific location for a shared purpose [14]. We applied this definition in our literature review but also included camp sessions of at least 100 participants because the cumulative aggregation of participants over the camp season can easily exceed 1,000 persons. Because NORS does not include a specific field for mass gatherings, we analyzed data from the NORS database

for outbreaks involving person-to-person transmission and transmission at camps, conferences, banquets, sporting events, and religious locations. Information on the setting for outbreaks involving other modes of transmission (e.g. water-borne) is not routinely reported to NORS. For all reported outbreaks, we used the number of persons exposed to approximate size of the mass gathering. We deferred to the author's definition of outbreak in our literature review. Disease events reported to NORS were assumed to meet CDC's outbreak definitions [13].

Systematic Literature Review. Six medical, behavioral, and social science literature databases were searched for relevant articles published from January 1, 2005 to December 31, 2014. These included Medline® (National Library of Medicine) and five non-Medline databases: Embase® (Excerpta Medica Database, Elsevier), Global Health, CAB Abstracts, Web of Science, and Scopus. A CDC reference librarian performed the initial search using the following strategy: ((mass OR public OR large OR general OR sport* OR community OR public) ADJ2 (gather* OR event* OR assembl* OR meeting*)) OR concert* OR theater* OR auditorium* OR amphitheater* OR Olympic* OR (world ADJ cup) OR festival* OR carnival* OR ((country OR county OR state OR world) ADJ fair*) OR world expo OR amusement park* OR cruise ship*AND Influenza OR pneumonia OR SARS OR flu OR H1N1 OR H3N2 OR coronavirus OR tuberculosis OR TB OR ((lung* OR respiratory) ADJ2 (infection* OR virus*)) OR MERS OR measles OR mumps OR acute respiratory syndrome OR legionnaires OR legionella OR infectious OR communicable OR illness OR disease* AND (transmission* OR outbreak OR epidemi* OR pandemic* OR cluster*) AND (at least one of the states in the United States).

To identify publications about outbreaks occurring at recreational, religious, cultural, and academic camps, the same search was repeated using the keywords (camp OR camping) AND Influenza OR pneumonia OR SARS OR flu OR H1N1 OR H3N2 OR coronavirus OR tuberculosis OR TB OR ((lung* OR respiratory) ADJ2 (infection* OR virus*)) OR MERS OR measles OR mumps OR acute respiratory syndrome OR legionnaires OR legionella OR infectious OR communicable OR illness OR disease* AND (transmission* OR outbreak OR epidemi* OR pandemic* OR cluster* OR spread) AND (at least one of the United States). We included "ADJ" as an adjacency operator to command the database to search for a word (or words) near another word within a certain number of words. For example, (mass ADJ2 outbreak) searched for the word "mass" within two words of the word "outbreak" picking up "mass outbreak" OR "outbreak during mass event". The search query varied slightly across the six databases (S1 File).

Only articles written in English were eligible for inclusion. Duplicate articles identified during the initial database search were removed prior to aggregating results in an EndNote file. The titles and abstracts of the remaining articles were reviewed by one person and categorized as relevant if the title included one or a combination of the following terms: mass gathering (or a specific event or setting associated with mass gatherings) and outbreak (or a specific syndrome or infection). The article was also included if the abstract, if available, described information on the occurrence of an infectious disease or illness at a mass gathering (or specific event or setting associated with mass gatherings). Articles on enteric or skin infections were excluded.

We reviewed each article that met the criteria in full. If the manuscript addressed our project objectives, then we completed a standard abstraction form for the article title, publication date, mass gathering name, venue type, dates, location, approximate size, and pathogen involved as well as the number of probable and confirmed cases, age groups of cases, likely outbreak cause and response of mass gathering organizers. At a minimum, each article included in our final analysis described the following: 1) purpose of gathering, 2) month and year of gathering, 3) location or venue type (indoor or outdoor), 4) type of syndrome or infectious disease outbreak, 5) number of confirmed or probable cases, 6) information on the index case(s), and 7) possible cause(s) of the outbreak. If not mentioned in the article, the approximate size of the mass

gathering was obtained by contacting the corresponding author or the mass gathering organizer. All project types were eligible for inclusion including outbreak investigation reports, case series, cross-sectional surveys, case-control studies, and intervention studies. No additional quality criteria for article inclusion were applied due to the variability in the study types [15]. Articles describing modeling studies, outbreaks on conveyances or at schools or businesses, policy papers, and outbreaks occurring before 2005 were excluded. We focused on mass gathering-related outbreaks occurring between 2005 and 2014 to provide a sufficiently long time frame to detect any trends or patterns before, during, and after the 2009 H1N1 pandemic while limiting results from the initial literature search criteria to a manageable size. Information from completed abstraction forms were entered into an Access database and imported into SAS for analysis.

National Outbreak Reporting System. NORS is a web-based national surveillance system for enteric waterborne, foodborne, person-to-person, animal associated, and environmental disease outbreaks as well as non-enteric waterborne outbreaks [13]. Health departments can voluntarily report outbreaks due to any other cause not mentioned above. NORS was fully deployed in 2009 and is maintained by CDC. We analyzed data from the NORS database for outbreaks involving person-to-person transmission that occurred between January 2009 and December 2013. Data describing water-borne outbreak were available through December 2012 only. Other available data included investigation methods, outbreak onset dates, number of exposed participants, total number of confirmed and probable cases, geographic location of the outbreak, and etiology, if known. Data were provided in an Access database and then imported into SAS (version 9.3, Cary, NC) for analysis.

Analysis

We generated descriptive statistics on the frequency, type, size, venue, geographic spread and dates of mass gathering-related respiratory disease outbreaks identified from the literature review and NORS database. Additional qualitative analysis was performed on information abstracted from the literature review on the causes of the outbreaks. No personal identifying information on individual patients was collected.

Ethics Approval

The project was reviewed by CDC's Human Subjects Research Office and approved as a public health evaluation activity.

Results

Published literature

The literature database search resulted in 835 articles (475 and 360 using the general mass gathering and camping keywords, respectively) (Table 1). We identified 54 articles as relevant from the initial review of titles and abstracts and included 9 additional articles identified from the references of these 54 articles. Of these 63 total articles, 21 were included in our analysis following full review [16–36]. We excluded 42 articles primarily because the article did not report a respiratory disease outbreak (n = 18, 43%) or was not related to a mass gathering (n = 9, 21%).

The 21 articles included 18 manuscripts describing 14 individual mass gathering-related respiratory disease outbreaks (the same outbreak could be described in more than one article) and three articles [21, 25, 36] describing pathogen-specific summaries of outbreaks across different settings and included 59 additional mass gathering-related outbreaks (Table 2, S2 File).

Table 1. Categorization of the published literature reviewed for identifying mass gathering-related respiratory disease outbreaks in the United States, January 1, 2005–December 31, 2014.

	General Mass Gatherings	Camps	From References	Total

[a]Databases included Medline® (National Library of Medicine) and five non-Medline databases: Embase® (Excerpta Medica Database, Elsevier), Global Health, CAB Abstracts, Web of Science, and Scopus.

doi:10.1371/journal.pone.0160378.t001

Thus, we identified 72 different mass gathering-related respiratory disease outbreaks. Of these, 1 occurred in 2005, 3 in 2007, 27 in 2009, 1 in 2011, 40 in 2012, and none in 2013 or 2014.

Fairs. More than half (n = 44, 61%) of the 72 identified outbreaks occurred at state or county agricultural fairs (Table 3). All of these fairs were large multiday events ranging between 5 to 12 days with a mean daily attendance of 33,000 persons (personal communication on subset of fairs for which data were available: Marla Calico, International Association of Fairs and Exhibitions). Forty outbreaks were reported between 2011 and 2012 and involved transmission of Influenza A H3N2v at fairs across 9 states. The largest outbreak occurred at an agricultural fair in Indiana and resulted in 73 confirmed and probable cases. In this, as well as other H3N2v outbreaks, the majority of case-patients reported close contact with swine at the agricultural fairs, though additional but limited secondary person-to-person transmission was detected [33–36]. Children and adolescents less than 18 years of age represented the largest percentage of case-patients (92%) during these outbreaks [36]. Three outbreaks of Influenza A H1N1 (3SIV) occurred at agricultural fairs in 2007 in Ohio, Illinois, and Michigan [20–21]. The swine barn housed 235 pigs belonging to 133 exhibitors and was closed as a result of the outbreak in Ohio [20]. A single case of Influenza A H3N2 (3SIV) was detected in a 12-year old boy after attending an agricultural fair in Kansas in 2009.

Camps. Twenty-seven (38%) of the 72 identified outbreaks occurred at residential recreational, academic, or cultural camps. Each lasted for three days or more and involved either Influenza A (H1N1) (n = 25) [22–29] or mumps (n = 2) [16–17, 30–31]. The size of most camp sessions was small, ranging between 100 to 600 campers and staff. Nineteen (76%) of the 25 Influenza A H1N1 (pdm09H1N1) outbreaks were reported from an online survey of 2009 summer camp participants in Maine [25]. In this survey, camp-related outbreaks (defined as having at least three confirmed cases of pdm09H1N1) were statistically associated with having both a larger number of camp participants per session and a larger number of campers per cabin. The six other camp-related pdm09H1N1 outbreaks occurred in North Carolina (n = 3) [22–23, 27–28], Louisiana (n = 1) [24], Alabama (n = 1) [26], and Washington State (n = 1) [29]. One outbreak involved 119 cases occurring across two clusters in a multi-camp setting at a North Carolina university with more than 7,900 participants [32–33]. The authors found that this transmission occurred rapidly during academic camps and was likely due to close and frequent

Table 2. Relevant articles about mass gathering-related respiratory disease outbreaks listed by year of outbreak and pathogen, identified from a literature review of articles published during 2005 and 2014.

Year[a]	Pathogen	Transmission	Type of Gathering	Location	Size of Gathering[b]	Length of Gathering (Days)	Estimated Number of Cases[c]	Age of Cases (Years)	Factors in outbreak	Reference
2005	Mumps	Person-to-person	Camp	New York	541	52	31	10–41	International importation of infectious case; Delayed diagnosis and reporting; Close social mixing and contact in communal housing/ activities	CDC [16]; Schaffzin JK, et al. [17]

[36]

[a]Reflects year during which initial outbreak-related case(s) were detected and reported.

[b]Estimated size of gathering obtained from article, personal communication with corresponding author or communication with the International Association of Fairs and Exhibitions (IAFE).

[c]Reflects case counts reported in the manuscript. Attack rates, when available, are reported in S2 File.

[d]Includes measles cases resulting from travel-related transmission.

[e]Indicates second reference to same outbreak.

[f]Includes only laboratory confirmed cases of Influenza A H1N1 (3SIV).

[g]Size and length of gathering combined across multiple-camps and 2 sessions.

[h]65 camp participants with influenza-like-illness across two camp sessions; 2 participants confirmed with Influenza A H1N1 during second session.

[i]Among 212 camp participants completing survey; 52 cases includes 49 camp participants (12 of whom were laboratory confirmed) and 3 identified from household contacts of ill camps participants.

[j]Camp closed early due to number of participants with influenza-like-illness and confirmation of 4 participants with Influenza A H1N1.

[k]Combined across 4 two-week sessions. In 3rd session, 12 cases identified (including 4 confirmed with Influenza A H1N1). In 4th session, 3 cases confirmed with Influenza A H1N1; cases aged 8 to 14 years.

[l]Numerous academic and recreational camps on university campus with length varying from 3 to 73 days, all camps closed early due to identified illnesses.

[m]Across two clusters; first involving 3 camps and 64 cases and second involving 2 camps and 55 cases.

[n]Includes 49 camp participants (from 96 campers responding to survey) and 11 additional cases among household contacts (of 136 household contacts from 41 households with an ill camper). Five camp participants confirmed with Influenza A H1N1.

[o]Outbreak spread to other counties in New York and New Jersey for total of 1,523 mumps cases.

[p]Includes 3 confirmed, 4 probable, and 82 suspected cases of Influenza A H3N2v.

[q]Estimates from IAFE based on available data from subset of fairs reporting Influenza A H3N2v cases; at time of project, no standards existed for calculating fair attendance.

doi:10.1371/journal.pone.0160378.t002

contact during classroom time and social mixing outside of class. Two camps (the university camp in North Carolina [27–28] and a camp for children with hematological and oncological conditions in Louisiana [24]) closed early due to the large number of participants presenting influenza-like-illness (ILI).

Two mumps outbreaks were identified in this review—both occurred at a camp for boys in upstate New York following international importations of infectious mumps cases from the United Kingdom. The first outbreak took place in 2007 and resulted in 31 cases among 541 campers and staff; the staff represented 60% of all case-patients [16–17]. The second occurred

Table 3. Frequency of mass gathering-related respiratory disease outbreaks identified from the published literature[a] by setting, pathogen, and mode of transmission, January 1, 2005–December 31, 2014.

Setting	Pathogen	Mode of Transmission	Outbreak Frequency
Fairs	Influenza A H3N2v	Zoonotic[b]	40
	Influenza A H1N1 (3SIV)	Zoonotic	3
	Influenza A H3N2 (SIV)	Zoonotic	1
Camps	Influenza A H1N1	Person-to-person	25
	Mumps	Person-to-person	2
Sporting events	Measles	Person-to-person	1
Total			72

[a]From 21 reviewed articles.

[b]Minimal person-to-person transmission detected.

doi:10.1371/journal.pone.0160378.t003

in 2009 and caused 25 cases among 400 campers and staff [30–31]. In both outbreaks, transmission was associated with prolonged close contact in communal housing and camp activities despite a two-dose MMR vaccination coverage > 85% among school-aged campers. A delay in mumps diagnosis also likely contributed to the 2007 outbreak. During the 2007 outbreak, camp activities were either cancelled or postponed [16–17]. These outbreaks resulted in substantial community transmission when campers returned home—more than 1,500 community cases (including 19 hospitalizations) occurred in New York and New Jersey in 2009 [30–31].

Sporting events. The final mass gathering-related outbreak identified in this review involved measles transmission at an international youth sporting event in Pennsylvania [18–19]. The youth sporting event outbreak was caused by the international importation of measles in a participant from Japan and resulted in six additional cases of measles. The index case from Japan infected three others before or during travel to Pennsylvania and a fourth case at the sporting event. The remaining two cases subsequently contracted measles in another state from the case-patient infected at the sporting event. Public health officials worked with event organizers to provide post-exposure measles-mumps-rubella (MMR) vaccination to close contacts of case-patients without documentation of at least two doses of measles vaccine or who were negative for measles IgG antibody [19].

Four of the 34 articles excluded from our analysis described health events at six large mass gatherings in Arizona between 2008 and 2011 [37], at Kansas Speedway NASCAR racing events between 2007 and 2010 [38], at the annual New York State Fair between 2004 and 2008 [39] and at a large (>40,000 participants) summer camp in Virginia in 2005 [40]. Analysis of syndromic surveillance data and/or onsite clinic records maintained at these gatherings identified heat or dehydration-related illnesses, injuries, and enteric infections as the most frequently reported conditions at these mass gatherings; no infectious respiratory disease outbreaks were detected. Additionally, no single-day mass gathering-related outbreaks were identified in our review.

National Outbreak Reporting System

Between 2009 and 2013, 1,114 outbreaks were reported to NORS (Table 4). This included 96 infectious respiratory disease outbreaks due to Legionella—all of which were reported as water-borne outbreaks (Legionella is not easily transmitted between human hosts). None of these outbreaks was linked to mass gatherings in our analysis. No other respiratory disease outbreaks were reported to NORS.

Table 4. Outbreaks reported to CDC's National Outbreak Reporting System (NORS), 2009–2013, by year and mode of transmission.

Mode of Transmission	2009 (%)	2010 (%)	2011 (%)	2012 (%)	2013 (%)	Total (%)
Foodborne	118 (62)	148 (58)	133 (61)	142 (58)	154 (74)	695 (62)
Waterborne[a]	51 (27)	78 (31)	66 (30)	71 (29)	—	266 (24)
Person-to-person[b]	10 (5)	17 (7)	6 (3)	16 (7)	25 (12)	74 (7)
Animal contact	10 (5)	12 (5)	13 (6)	14 (6)	15 (7)	64 (6)
Environmental	1 (<1)	0 (0)	0 (0)	0 (0)	0 (0)	1 (<1)
Unknown/indeterminate	0 (0)	0 (0)	0 (0)	0 (0)	14 (7)	14 (1)
Total	190	255	218	243	208	1,114

[a]At time of analysis, 2013 waterborne disease outbreak data were not available. Waterborne transmission includes 96 legionellosis outbreaks; none were linked to mass gatherings.

[b]Person-to-person outbreaks (n = 74) were due to Norovirus (45), *Escherichia* (3), *Salmonella* (1), *Shigella* (1), and *Campylobacter* (1). The remaining 23 outbreak reports were missing etiology information.

doi:10.1371/journal.pone.0160378.t004

Discussion

To the best of our knowledge, this is the first effort to describe the frequency and characteristics of mass gathering-related respiratory disease outbreaks occurring in the United States. Mass gathering-related respiratory disease outbreaks appeared to be relatively rare during our 10-year project period, but were reported from agricultural fairs (zoonotic transmission) and summer camps where participants had close social contact in communal housing. Though legionellosis outbreaks were more common, none of these water-borne outbreaks was linked to a mass gathering in our analysis. The type and duration (multi-day events with communal housing) of mass gatherings could be important factors in mass gathering-related respiratory disease outbreaks. International participation may be a contributing factor for certain diseases.

As anticipated, we identified several mass gathering-related pdm09H1N1 outbreaks involving school-aged children [41]. These persons are a high-risk age group for the novel 2009 influenza virus. Compared to other settings, influenza transmission among children and teenagers is more likely to occur within households, school classes, peer groups, and sports teams [42–44]—all of these social mixing opportunities are prominent at summer camps. Children and adolescents can easily have more than 20 close contacts with other children lasting 5 minutes of more during a typical school day [45]. Both the number and duration of close contacts could be higher in residential camps. This is supported by the outbreaks reported from Maine where the camp size and the number of campers per cabin were associated with influenza outbreaks [25]. Though respiratory disease transmission can occur at summer camps, influenza transmission during the summer (in the United States) outside a pandemic is uncommon; pdm09HIN1 was circulating since early spring and was involved a number of school-based outbreaks in states reporting camp-related influenza outbreaks in summer 2009. No respiratory illnesses were detected from a syndromic surveillance system implemented at a large school-aged summer camp in Virginia in 2005 [40].

The majority of the other mass gathering-related respiratory disease outbreaks identified in this project occurred at agricultural fairs and was caused by Influenza A H3N2v. Prior to 2011–2012, human Influenza A (SIV) infections were rare; however, the H3N2v outbreaks resulted from the reassortment of swine Influenza A H3N2 virus and Influenza A pdm09H1N1 in the swine population, raising concerns about sustained human-to-human transmission and increased risk in the pediatric population [46]. Though only minimal human-to-human transmission of H3N2v was detected, close and repeated contact between humans and livestock at the estimated 2,380 agricultural fairs (personal communication: Marla J. Calico, International

Association of Fairs and Exhibitions) that take place each year in the United States could create future opportunities for zoonotic transmission of influenza viruses as well as other possible respiratory infections [34, 36]. The syndromic surveillance system using emergency department chief complaint data was analyzed to detect the initial H3N2v outbreak in Indiana (personal communication: Shawn Richards, Indiana State Department of Health). This highlights the usefulness of such systems to rapidly detect temporal or spatial clusters of unusual health events associated with fairs and other mass gatherings.

The mumps and measles outbreaks demonstrate the importance of close collaboration between public health officials and mass gathering organizers to assess health risks to participants. As recommended in the articles, camp and sporting event organizers should verify immunization histories of all registered participants and team members [17, 31]. This is particularly important for measles, which is highly contagious through aerosolized viral particles; other control and prevention measures are likely to be ineffective. Organizers should also obtain information on disease transmission in the home countries of participants. These pre-gathering activities can help with the early case detection and outbreak prevention. The 2007 mumps outbreak, for example, was attributed to the international importation of mumps in a staff member followed by the delayed recognition of suspected mumps cases and prolonged and close contact between campers in communal housing [16–17].

NORS was developed to capture outbreaks related to enteric infections such as Norovirus, Shigella, and Salmonella as well as non-enteric waterborne diseases such as Legionnaires—an infection caused by a bacterium found naturally in the environment [47]. Though we could use exposure setting (e.g., camps, conference, etc.) as a proxy for mass gathering, this exposure setting was only reported for outbreaks involving person-to-person transmission. The 96 reported legionellosis outbreaks were unrelated to mass gatherings according to available data. A previous review of environmental and waterborne outbreaks reported to NORS between 2011 and 2012 indicated that the 4 (22%) of the 18 legionellosis outbreaks occurred at hotels; however, there was no additional information to determine on whether visitors or detected cases were involved in hotel-based conferences or other mass gatherings [48].

No other mass gathering outbreak due to pdm09H1N1 or other respiratory diseases was identified in this project including at large mass gatherings in Arizona, Kansas, New York, and Virginia [37–40]. This is consistent with previous assessments of international mass gatherings such as the Olympics that detected only marginal increases above baseline in the incidence of all infectious diseases including influenza with infections primarily limited to competitors and staff [5, 47]. Though we assume that all mass gatherings could increase the transmission of respiratory diseases, this may not be the case for diseases transmitted through infectious droplets where the probability of close and adequate contact (i.e., $<$ 6 feet for influenza) with an infectious person may be too low for efficient transmission [49]. Even at large mass gatherings involving out-of-town visitors such as the May 2009 convocation speech in Arizona (during which no respiratory disease outbreaks were detected) [37], most participants likely stayed at hotels or at other low-density accommodations rather than in cabins or at campgrounds [5, 49]. In addition, many of these gatherings have well organized and pre-assigned seating. This could further reduce the 'crowdedness' and likelihood of close and prolonged contact with infectious persons [5]. This can be contrasted to the type of communal housing and social mixing associated with camp outbreaks described here. Variability in susceptibility among attendees as well as in the timing of the gathering in relation to local respiratory disease activity also likely play a role in transmission [9].

Our findings have several limitations. First, only a small percentage of outbreaks are likely reported in the literature. We used a broad database search criteria to minimize this limitation and identify all possible articles describing mass gathering-related respiratory disease

outbreaks. Second, some outbreaks may not be identified as outbreaks. Active or passive surveillance likely influences the number of infectious respiratory disease outbreaks identified and reported. For example, active surveillance for variants of influenza viruses at fairs following the initial H3N2v outbreak in 2011 could have increased the number of outbreaks detected from this setting. In addition, while multiday residential-based mass gatherings can facilitate transmission, these settings may also help identify cases and an emerging outbreak through close monitoring of known participants. In non-residential settings, other non-disease related factors including crowd mood, age, weather, and alcohol and drug use could influence the use of illness-related medical services. These factors could further increase the variability of health event reporting [14]. Third, some respiratory diseases with longer incubation periods and many subclinical infections are unlikely to be identified during the mass gathering. Symptoms could appear once the participants have returned home and are then rarely linked or reported to the appropriate surveillance system [9, 49].

Advances in technology such as crowdsourcing applications (e.g. Flu Near You at URL: https://flunearyou.org and GermTrax at URL: http://germtrax.com) [50] as well as an increased use of social media along with real-time outbreak and syndromic event reporting could help address some of the surveillance limitations at mass gatherings. In Brazil, for example, a smart phone application was developed allowing persons attending the 2014 FIFA World Cup to provide information on their daily health status. This information was automatically aggregated into reports that were reviewed daily to identify potential infectious disease clusters or outbreaks [51]. Monitoring social media including Twitter was used to identify potential health issues and communicate accurate information about disease transmission during the 2012 London Olympics [52]. These approaches can complement other surveillance systems such as collection and analysis of syndromic event data from emergency department visits or onsite medical clinics [37]. Integration of these various platforms through a web-based system could allow public health officials to rapidly detect unusual disease activity [10, 53] even at smaller mass gatherings [54–55]. Recent research has also focused on the use of radio frequency identification devices [56–57] as well as video analysis technology [58] to capture social mixing and contact patterns at mass gatherings. These contact data can be used to simulate or model the transmission of various infectious disease pathogens including pandemic influenza. Simulations or mathematical models can help describe the risk of potential outbreaks and highlight where and when enhanced disease transmission mitigation at mass gatherings should be considered.

Finally, NORS was developed primarily to capture outbreaks related to enteric infections as well as non-enteric waterborne diseases such as Legionnaires. Voluntary reporting of other types outbreaks likely impacted the probability of identifying mass gathering related respiratory disease outbreaks from the NORS database. However, because state and local health departments are familiar with this system, NORS could incorporate standard mass gathering and additional outbreak definitions and serve as a platform to monitor mass gathering-related respiratory outbreaks in the future.

Conclusion

We identified a relatively small number of mass gathering-related respiratory disease outbreaks occurring in the United States between 2005 and 2014. This could suggest a low risk of respiratory disease transmission at most types of gatherings—even during a pandemic. However, because not all outbreaks are reported in the published literature or to NORS, a follow-up state and local health department assessment on the number and characteristics of mass gathering-related respiratory disease outbreaks could help validate or complement the findings reported

here. Additional research to strengthen existing surveillance approaches to detect outbreaks and better quantify the social mixing patterns at different mass gatherings could provide additional insight into the types of mass gatherings at greatest risk of respiratory disease outbreaks.

Acknowledgments

We greatly appreciate Ms. Joanna Taliano, CDC Reference Librarian, for her suggestions and time in conducting the literature database searches for this project. We also thank CDC staff with the National Outbreak Reporting System for providing guidance and feedback during our analysis of the NORS database. The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of CDC.

In the minds of many, large scale open air festivals have become associated with spring and summer, attracting many people, and in the case of music festivals, thousands of music fans. These festivals share the usual health risks associated with large mass gatherings, including transmission of communicable diseases and risk of outbreaks. Large scale open air festivals have however specific characteristics, including outdoor settings, on-site housing and food supply and the generally young age of the participants. Outbreaks at large scale open air festivals have been caused by *Cryptosporium parvum, Campylobacter spp., Escherichia coli, Salmonella enterica, Shigella sonnei, Staphylococcus aureus*, hepatitis A virus, influenza virus, measles virus, mumps virus and norovirus. Faecal-oral and respiratory transmissions of pathogens result from non-compliance with hygiene rules, inadequate sanitation and insufficient vaccination coverage. Sexual transmission of infectious diseases may also occur and is likely to be underestimated and underreported. Enhanced surveillance during and after festivals is essential. Preventive measures such as immunisations of participants and advice on-site and via social networks should be considered to reduce outbreaks at these large scale open air festivals.

Introduction

Mass gathering (MG) medicine is an emerging specialty [1] that includes effective strategies and planning to address health security and risks associated with MGs. The number of attendees that classifies an event as a 'mass gathering' is wholly arbitrary. Definitions vary greatly, with some sources specifying any gathering to be a MG when more than 1,000 individuals attend, whereas others require the attendance of as many as 25,000 people to qualify [2]. Outbreaks, however, occur irrespective of the size of a gathering and are described not only in settings such as private parties, weddings, and other events involving fewer than 1,000 attendees, but also in large MGs, such as religious MGs, attended by millions of people [3]. In addition to the number of people, MGs are events at a specific site for a definite time which may greatly vary between different MGs. These gatherings might be planned or unplanned and recurrent or sporadic.

Although large scale open air festivals have become important spring and summer activities and attract thousands of people, they are probably neglected, particularly music festivals, in terms of public health attention, as well as surveillance and prevention of infectious disease strategies, compared to other categories of MGs such as sport or religious events. Indeed, most of the literature on MGs in this respect, has addressed health issues related to very large MGs, including the Hajj [2] and the Olympic Games [4].

A characteristic of large scale open air festivals, including music festivals, may be that they are not always organised and managed by professionals and may involve inexperienced volunteers as staff members. Music festivals in particular have also specific characteristics, including outdoor settings, on-site housing and food supply, the young age of the participants, recreational motivations, and the potential for excessive alcohol or drug consumption, which may notably increase the risk of sexually transmitted infections (STIs) [5] and possibly of other infectious diseases.

A total of 858 music festivals were recorded worldwide in 2012 in choosefest database (www.choosefest.com/). The largest music festivals were in Europe where 13 of the 20 top international festivals occur (Table 1). Most festivals take place over a three to four day period with the longest lasting 11 days. Attendance for the top 20 festivals in terms of size ranges from 17,000 to 175,000 per day. According to a survey conducted in the United Kingdom (UK) during the year 2009, the total number of visits to UK music festivals was estimated to exceed 7.7 million attendees, including overseas and domestic participants combined (www.ukmusic.org/assets/media/UK%20Music%20-Music%20Tourism.pdf). Music festivals, which may involve as many as 400,000 cumulated attendees, share the usual health risks associated with large MGs, including communicable and non-communicable diseases [6-8]. A mean percentage of 1.5% attendees at music festivals seek medical care during these events, and the highest proportion recorded of attendees seeking care was 10% [9-12]. This situation may have an impact on local healthcare facilities, especially

Table 1

Top 20 international music festivals by estimated attendance per day, 2012

Festival	Location	Duration (days)	Estimated attendance per day
Glastonburry	Worthy Farm, Pilton, Shepton Mallet, Somerset, United Kingdom	5	175,000
Roskilde	Roskilde, Denmark	4	110,000
Rock Werchter	Werchter, Belgium	4	110,000
Rock al Parque	Bogota, Colombia	4	88,600
T in the Park	Balado, Kinross-Shire, Scotland	3	85,000
Summerfest	Henry Maier Festival Park, Milwaukee, Wisconsin, United States	11	82,000
Exit	Petrovaradin Fortess, Novi Sad, Vojvodina, Serbia	4	75,000
Coachella	Coachella, California, United States	3	75,000
Reading-Leads Festival	Reading, Leads, United Kingdom	3	75,000
Sziget	Budapest, Hungary	6	65,000
Pukkelpop	Kiweit-Hasselt, Belgium	3	62,500
Pinkpop	Landgraaf, Netherlands	3	60,000
Big Day Out	Gold Coast, Sydney, Melbourne, Adelaide, Perth, Australia and Auckland, New Zealand	11	56,000
Burning Man	Black Rock Desert, Nevada, United States	7	50,000
Bonnaroo	Great Stage Park, Manchester, Tennessee, United States	4	40,000
Fuji Rock	Naebi Ski Resort, Japan	3	40,000
Hurricane	Scheeßel, Lower Saxony, Germany	3	40,000
Downlaod	Donington Park, United Kingdom	3	37,000
Benicassim	Benicassim, on the coast between Valencia and Barcelona, Spain	4	32,000
Wireless	Hyde Park, London, United Kingdom	3	17,500

Sources: http://www.wikifestivals.com/wiki/list-international-music-festivals-attendance, http://www.cnbc.com/id/42150834/The_Worlds_s_Biggest_Music_Festivals, http://en.wikipedia.org/wiki/Music_festivals.

in terms of the workload on local hospitals, as found in Punchestone Racecourse, Ireland in 2004 [13]. During the Oxegen festival, which had 80,000 attendees over three days, a 45% increase in admissions to the emergency department (mainly for trauma) was observed at Nass General Hospital, with 51% of these admissions treated as inpatients. Interestingly, 47% of these patients had consumed alcohol and/or drugs [13].

A comprehensive review on outbreaks in relation to large scale open air festivals is missing. The objective of this report is to summarise the evidence related to the substantial challenges posed by communicable diseases to the organisers of large scale open air festivals, including music festivals, and outline details of infections resulting from faecal-oral, respiratory and sexual transmission. Opportunities to control these outbreaks are discussed.

Methods

Definition of large scale open air festivals

Outbreaks in the setting of an open air festival, including a music festival or other art festival, village festival, cultural festival, university, religious events and large weddings were included.

Case reports and human/non-human experimental laboratory studies were excluded from the review. Outbreaks in relation with sport events, Hajj pilgrimage, food festivals, fairs or occurring in the setting of cruise ship, school, restaurant or hotel (including weddings at restaurants or hotels) were excluded because they were reviewed elsewhere [6-8].

Search strategy

To retrieve information on the transmission of infectious diseases and outbreaks during large scale open

air festivals, we first conducted a literature search using the MEDLINE database (www.ncbi.nlm.nih.gov/pubmed), from 1980 to July 2012, cross-referencing the following terms: 'mass gatherings', 'festivals' or 'music festivals' and 'infection' or 'infectious diseases' or 'outbreak'. Only studies published in English, but one in Serbian, were included in this review. Relevant systematic and narrative reviews were also utilised for useful background information. Subsequently, the reference lists of the systematic reviews and other identified papers were scanned for potentially relevant primary studies that could be considered for inclusion in the review. Additional search was conducted using ProMED-mail (www.promedmail.org) cross-referencing the following terms: 'festivals' or 'music' and through Google (www.google.fr) and Yahoo (fr.yahoo.com) general search-engines cross-referencing the terms: 'festivals' or 'music festivals' and 'infectious' or 'outbreak'.

Results

Using our search strategy, 107 articles were retrieved through MEDLINE and scanning of reference lists, and 23 of these were relevant to our subject from a review of titles, abstracts, and full text of the articles obtained. Pro-MED mail search allowed identifying only three relevant outbreaks that were already retrieved through MEDLINE. Google and Yahoo search retrieved respectively 31,900,000 and 12,400,000 hits, using 'festival' and 'outbreaks' terms; 6,670,000 and 11,300,000 hits, using 'music festival' and 'outbreaks' terms and 558,000 and 200,000 hits, using 'music festival' and 'infectious' terms. Given the poor relevance of search results obtained through Google and Yahoo, no further analysis was conducted using these two search-engines.

Outbreaks and infectious diseases occurring during large scale open air festivals were classified into three categories: (i) faecal-oral transmission and gastrointestinal diseases, (ii) respiratory transmission and respiratory infections and (iii) blood-borne and sexually transmitted diseases.

Faecal-oral transmission and gastrointestinal diseases

A total of 10 outbreaks of gastrointestinal infections associated with faecal-oral transmission in the context of large scale open air festivals were retrieved and are summarised in Table 2. Of these five were linked to music festivals. Outbreaks of *Cryptosporium parvum, Campylobacter, Escherichia coli, Salmonella enterica, Shigella sonnei, Staphylococcus aureus*, hepatitis A virus and norovirus infections have been described over the last two decades in the United States (US), Canada, Europe and Japan and have been as well associated with events including 350 attendees, as with open air festivals involving as many as 80,000 participants. In some outbreaks, the attack rate was close to 50% of attendees, such as in Shigella outbreaks [14,15] or gastroenteritis outbreaks due to norovirus [16].

Failures of hand-washing hygiene among food handlers suspected to be infected by the infectious agent lead to the contamination of food and were an important route of transmission for gastrointestinal diseases at large scale open air festivals [14,17-19]. A lack of respect for food hygiene rules has also been observed during such festivals [17,18,20]. Factors that contribute to gastrointestinal outbreaks at these festivals include (i) excessive production of food beyond the safe food production capacity [17], (ii) preparation of meals by a large number of volunteer food handlers [14,18], and (iii) the sale of food prepared under unsanitary conditions, sometimes by vendors without a license [19-21]. Moreover, during a lunchtime concert in Cardiff, the most likely cause of the outbreak of norovirus infection was vomit contaminating inadequately cleaned and disinfected hard surfaces, carpets and soft furnishings [16].

Another important factor associated with the risk of gastrointestinal infections is the lack of adequate sanitation. Inadequate sanitation was the cause of the contamination of drinking water during the annual meeting of the Rainbow Family in the US in 1987, resulting in a large outbreak of shigellosis [15]. Inadequate sanitation associated with limited access to running water for hand washing has also been reported as the source of gastrointestinal outbreaks [14].

Unusual transmissions of gastrointestinal diseases have also occurred during large scale open air festivals. An outbreak of Escherichia coli O157 was reported during the Glastonbury music festival in England and was linked to mud contaminated by infected cattle. Heavy rain had turned the site into a quagmire, and attendees had high levels of contaminated mud on their hands and faces [22]. Additionally, a swimming pool at an accommodation during a dance festival in Canada was identified as the source of an outbreak of diarrhoea due to *Cryptosporidium parvum* [23].

Overall, the estimated incidence of gastrointestinal diseases per 100,000 attendees ranged from nine to more than 55,000 during the outbreaks included in this review.

Respiratory transmission and respiratory infections

Infections acquired by respiratory routes reported in the literature in association with nine large scale open air festivals are described in Table 3. Of these, three were music festivals.

Influenza outbreaks have been reported at music festivals [24-27], with the potential for the spread of new influenza viruses in some cases [27,28]. In Serbia in 2009, 40% of the pandemic influenza A(H1N1)pdm09 cases were linked to the Exit festival [26]. Interestingly, during 2009, influenza A(H1N1)pdm09 outbreaks were recorded at three of the top six music festivals (>100,000 cumulated attendees) in Europe (Rock

Table 2

Outbreaks of gastrointestinal diseases associated with large scale open air festivals, 1987–2008

Reference	Event	Place	Year	Size (cumulated number of attendees) and type of attendees[a]	Pathogen involved	Case numbers	Estimated incidence per 100,000 attendees	Indication of patient age	Source of outbreak	Mode of transmission	Favouring factors
[15]	Annual meeting Rainbow Family	Nantahala National Forest, United States	1987	12,700	*Shigella sonnei*	Estimated >7,000; nationwide dissemination (3 States)	55,118	Mean patient age: 27 years	Inadequate sanitation	Food-borne, water-borne, person-to-person	Inadequate sanitation
[14]	Michigan Women's Music Festival	Michigan, United States	1988	6,403 women	*Shigella sonnei*	3,175 primary cases (278 ill staff and 2,897 ill attendees); 182 secondary cases; 117 hospitalisations	45,244	Mean patient age: 31 years	Uncooked tofu salad	Food-borne and person-to-person	Limited access to soap and running water for hand washing and large number of non-professional food handlers
[20]	Glastonbury music festival	South west England	1992	70,000	*Campylobacter*	72	103	Age range of the majority of patients: 20–30 years	Unpasteurised milk	Food-borne	Lack of respect for food hygiene rules
[22]	Glastonbury music festival	South west England	1997	80,000	*Escherichia coli* 0157	7	9	Mean patient age: 21 years	Mud (contaminated by cattle faeces)	Direct contact	Grazing of cattle on site two days before the event and heavy rain
[16]	Lunchtime concert	Cardiff, England	1999	1,229 children	Norovirus	>300	24,410	Primary school students	Vomits inappropriately cleaned	Direct contact	Vomit inappropriately cleaned
[23]	Ukrainian Dance Festival	Dauphin, Manitoba, Canada	2001	430 dancers, >450 spectators	*Cryptosporidium parvum*	59 (2 hospitalisations)	13,111	Mean patient age: 23 years	Swimming pool	Faecal-oral	Swimming pool in one accommodation
[17]	San Juan Festival	Catalonia, Spain	2002	ND	*Salmonella enterica*	1,435 (117 hospitalisations)	ND	Age range of 24% of patients: 1–24 years; of 35%: 25–44 years	Pastry with vanilla cream	Food-borne	Exceeded food production capacity
[19]	Youth camp	Australia	2003	350	Hepatitis A virus	21	6,000	Median patient age: 16 years	Coleslaw	Food-borne	Infected food handler
[21]	Outdoor concerts 'jam bands'	United States (9 States)	2003	1,200–82,000	Hepatitis A virus	25	31–2,083	Median patient age: 23 years	Unknown	Person-to-person, food-borne	Unknown
[18]	Nagoya University Festival	Japan	2008	50,000	*Staphylococcus aureus*	75 (staff and attendees)	150	ND	Crepes	Food-borne	Lack of respect for food hygiene rules

ND: not determined.

[a] When attendees were of a certain type.

Table 3

Outbreaks of respiratory transmissions and infections associated with large scale open air festivals, 2006–2010

Reference	Event	Place	Year	Size (cumulated number of attendees)	Outbreak type	Number of cases and description	Estimated incidence per 100,000 attendees	Age of patients as specified	Favouring factors/ consequence
[31]	Easter Youth Festival	Carinthia, Austria	2006	ND	Mumps virus	214 cases (143 confirmed, 71 probable)	ND	Age range of 80% of patients: 16–30 years	Occurrence in unvaccinated people
[32]	Annual village festival	Navarra, Spain	2006	› 4,500	Mumps virus	19 primary cases; 58 secondary cases	422	Age range: 18–37 years	Failure in immunisation by Rubini strain
[28]	World Youth Day (religious meeting)	Sydney, Australia	2008	500,000	Numerous influenza virus strains (A and B)	100 confirmed cases	20	Median age: 21 years	Community strains from Australia that were rarely isolated before World Youth Day 2008 were frequently identified among pilgrims; novel influenza viruses were introduced
[27]	Iztapalapa Passion Play (religious meeting)	Iztapalapa, Mexico	2009	>2 million	Influenza A(H1N1) pdm09 virus	38 cases; of 202 cases of influenza A(H1N1) pdm09 in Mexico from 1 to 5 May 2009, 38 originated from the Iztapalapa Passion Play meeting	2	Age range of 32% of patients: 5–19 years; of 28%: 20–29 years	Local and national spread, start of the pandemic influenza A(H1N1)pdm09
[24]	Rock Werchter (music festival)	Belgium	2009	113,000	Influenza A(H1N1) pdm09 virus	14 confirmed cases; 30 ILI cases	12	Mean age: 23 years	International spread
[25]	Sziget Festival (music festival)	Budapest, Hungary	2009	390,000	Influenza A(H1N1) pdm09 virus	8 confirmed cases; 14 ILI cases	2	Mean age: 21 years (personal communication, Dr Peter Felkai, January 2010)	International spread
[26]	Exit Festival (music festival)	Novi Sad, Serbia	2009	165,000	Influenza A(H1N1) pdm09 virus	49 confirmed cases	30	Age range of 42% of patients: 20–29 years	During 2009, 40% of influenza A(H1N1) pdm09 cases in Serbia were linked to this festival
[29]	Taizé (religious meeting)	France	2010	3,500	Measles virus D4-Manchester	13 primary cases; 17 secondary cases; 7 tertiary cases	371	Median age for primary cases: 17 years; for secondary cases: 15 years; for tertiary cases: 13 years	Low vaccine coverage
[30]	Wedding	Andalucia, Spain	2010	ND	Measles virus	25 primary cases; 58 secondary cases	ND	97% of patients ›16 years-old	Low vaccine coverage

ILI: Influenza-like illness; ND: not determined.

Werchter, Belgium; Sziget Festival, Hungary; and Exit Festival, Serbia).

In 2010, 13 primary measles cases were identified among unvaccinated persons aged between nine and 32 years-old in 11 districts in Germany. All cases had attended religious meetings in Taizé, France [29]. This outbreak illustrates the risk of long distance spread of infectious diseases associated with international large scale open air festivals. The same year, 25 primary cases of measles had been reported from Granada, southern Spain, of whom 22 were unvaccinated children under the age of 15 years [30]. This outbreak involved a subpopulation with low vaccination coverage and parents with ideological objections to vaccination participating to a large wedding reception [30]. Secondary cases were documented in both outbreaks.

An outbreak of mumps occurred in Austria in 2006 involving 214 individuals. Nearly half of the cases for whom vaccination status was known occurred in non-vaccinated persons, another 40% were vaccinated with one dose of vaccine. The majority of cases (80%) occurred in persons between 16 and 30 years of age with a peak in the age group of 21 to 25 years (42%). Considering the minimum incubation period of 10 to 14 days, the mumps outbreak probably originated with virus transmissions to susceptible individuals at a village Easter festival [31]. In 2006 too, a mumps outbreak including 19 primary cases was recorded in a village in Spain. Patients' ages ranged between 18 and 37 years and 94% of the patients reported attending the annual festival held in the village. 58 secondary cases were reported [32].

Overall, the estimated incidence of confirmed respiratory infections per 100,000 attendees ranged from two to more than 420 during the outbreaks included in this review.

Sexual and blood transmission of infectious diseases

During music festivals, the risk of transmission of sexual or blood-borne infections is considered important, but this consideration is mainly speculative. Indeed, this risk is difficult to assess. Some of these infections have long incubation periods, making it difficult to relate the infection to the event. Despite the lack of evidence for the transmission of such diseases at festivals, the consumption of drugs and alcohol during music festivals is known to be high and may lead to at-risk behaviours, particularly unprotected sexual behaviours [5,33,34]. To our knowledge, the sexual-risk behaviour of participants during music festivals has been evaluated at several times only during the Big Day Out, one of the biggest music festivals in Australia [33,35]. Among sexually active participants, 43% reported not using a condom because of alcohol use [33]. Knowledge of STIs was poor overall [33]. In this young population (89% in the age group 16–24 years), surveillance of STI risk behaviour between 2005 and 2008 indicated that reporting having had a recent STI test increased from 23% in 2006 to 32% in 2008 [35]. Attempts to test for Chlamydia infection during the Big Day Out in 2009 has not been effective, with only 21% of participants returning the test and only one diagnosed case of Chlamydia infection [36].

Discussion

We describe various outbreaks related to large scale open air festivals, highlighting the fact that at these gatherings of people where the majority of attendees are aged 15 to 30 years, transmission of infections occurs at local, national [15,17,21] and international levels [24,25,29], as found during larger MGs [8]. Within open air festivals, music festivals contributed a large proportion of the outbreaks.

The outbreaks published in MEDLINE and ProMED are probably a tiny and heavily biased subset of all outbreaks associated with large scale open air festivals. This constitutes a limitation of our study and may explain the geographical repartition of the outbreaks included in our review. Unfortunately, general search-engines like Google and Yahoo are not sufficiently accurate tools to further identify outbreaks. Even the US Centers for Disease Control and Prevention foodborne outbreak online database (wwwn.cdc.gov/foodborneoutbreaks/Default.aspx) does not allow a distinction between festivals, fairs, and other temporary or mobile services.

During large scale open air festivals, respiratory infections can easily be transmitted due to overcrowded conditions which may contribute to the spread of new influenza viruses, as reported during the 2009 pandemic [25,26]. The risk of transmission and of the introduction of new strains of viruses in countries hosting MGs or large scale open air festivals has been documented at such events [8,27,28]. Therefore, risk assessment and the establishment of preventive strategies should be implemented in preparation for large scale open air festivals, as for other MGs. Measles is one of the most contagious human diseases, with a basic reproduction number ranging from 7.7 to 15 in a susceptible population [37]. Increased numbers of cases have recently been observed in young adults, notably in Europe [38]. Therefore, it is not surprising that measles outbreaks have occurred during youth festivals [29,30]. Interestingly, although immunisation programmes are required for certain MGs, such as the Hajj [8], there is no immunisation recommendation for large scale open air festivals.

Outbreaks of vaccine-preventable diseases, including hepatitis A, influenza, measles and mumps, have been reported in connection with large scale open air festivals [19,21,24,25,29-32] and could have been prevented by adequate vaccination coverage in the populations taking part. Although meningitis outbreaks have not been associated with large scale open air festivals, they have been described in the context of

the Hajj [8]. Vaccination against meningococcus may be considered for young people planning to participate in a large scale open air festival. The use of drugs and alcohol is common at large open air festivals and may theoretically increase the risk of transmission of STIs and blood-borne diseases [5,13,33].

A high incidence of Shigella, norovirus, *Cryptosporidium parvum* and hepatitis A virus infections was found among attendees of large scale open air festivals where outbreaks were reported compared to their respective incidence in the general population, suggesting that increased transmission of gastrointestinal infections may also occur in these settings. In contrast, no evidence for substantial increased risk of outbreaks of gastrointestinal infectious diseases was found during large international sport events notably due to proper sanitary supervision of food preparation and of water sources in these events [39]. Among previous outbreaks of gastrointestinal diseases reported at large scale open air festivals, the role of inadequate sanitation has been highlighted [14,15]. Good sanitation is therefore critical even at the smallest gatherings, where the organisation is often non-professional. Respect for hygiene rules for food handling is also critical to avoid food-borne disease transmission. In particular, the role of volunteers in food preparation should be examined. They constitute a potential risk because they are not trained in the necessary hygiene measures [14].

The discrepancy between sport events and large scale open air festivals in terms of infectious diseases may also be the consequence of the relatively short duration of sport events which frequently last shorter than one day, with many participants moving to other locations at the end of the event and who do not live on site [39]. In contrast, large scale open air festivals last several days with most attendees staying on site during the event, sharing accommodations and sanitations. In an old study conducted in 1972, the overall incidence of communicable diseases was 75 per 100,000 attendees during a 2.5 day music festival and 580 per 100,000 during a seven day-long music festival, suggesting that the length of exposure is a contributing factor to transmission of infectious diseases in the specific setting [10].

To prevent infectious diseases, communication and on-site advice about infectious risks should be implemented and hand-washing hygiene, cough etiquette and condom use should be promoted. Reminding people before festivals to check whether they have been immunised for certain vaccine preventable diseases including measles, mumps and influenza should be promoted. To prevent STIs and blood-borne diseases, campaigns involving the free distribution of condoms and syringes for intravenous drug users may be proposed.

Finally, surveillance after large scale open air festivals with participant recall may be implemented to better address infectious disease threats of international concern at the earliest possible stages. Social networks such as Twitter or Facebook can assist with active surveillance (e.g. public health outreach on Twitter or Facebook for people reporting health related issues in the host city during a festival and for people participating in a festival). Social media can function also as a method of passive surveillance (e.g. analysis of geographically tagged tweets). Mobile phones, particularly mobile internet use, facilitate the availability of real-time information at any time and nearly anywhere in the world to the general public and may be useful in this context [4]. Surveillance could also be operated through specialised networks reporting on travel-associated diseases, including GeoSentinel [40] and EuroTravnet [41]; however participation to large scale open air festival and MGs is not documented specifically at the moment in these databases.

Conclusions

Infections related to large scale open air festivals may be under-reported given the important number of these festivals worldwide. Alternatively these could also possibly be overestimated due to 'common sense' assumptions about conditions at festivals. We assume that most outbreaks probably remain unnoticed and underreported. The relationship between infections and festivals may be difficult to establish, especially for diseases with long-incubation periods and international events, as the participants spread worldwide. Cases could have been classified under 'travel-related' infections since participation to festivals or other MGs is usually not documented in surveillance networks records. We cannot give an estimate of the frequency of communicable diseases during large scale open air festivals, because of the relative paucity of published data. The creation of an online event and patient registry should overcome this gap [42].

During an event, syndromic surveillance associated with the use of adequate laboratory facilities may help to recognise the first cases of an outbreak although the value of syndromic surveillance during MGs is highly debated [43].

Preventive measures including immunisation of people participating in large scale open air festivals and targeted on-site advice about food hygiene, hand hygiene, cough etiquette and the use of condoms may be considered. However, the effectiveness of such preventive measures in the context of MGs has not been established and research is needed before this could be recommended [44]. Finally, strict adherence to food safety protocols and adequate sanitation should be promoted to prevent gastrointestinal diseases. The presence of on-site medical staff has proven to be cost-effective in improving the medical management of injuries and other health issues, such as infections [45].

REVIEW

Outdoor Transmission of SARS-CoV-2 and Other Respiratory Viruses: A Systematic Review

Tommaso Celeste Bulfone,[1] Mohsen Malekinejad,[2] George W. Rutherford,[2,3] and Nooshin Razani[2,3]

[1]Joint Medical Program, University of California Berkeley-University of California San Francisco, Berkeley, California, USA, [2]Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, California, USA, and [3]Department of Pediatrics, University of California San Francisco, San Francisco, California, USA

Background. While risk of outdoor transmission of respiratory viral infections is hypothesized to be low, there are limited data on SARS-CoV-2 transmission in outdoor compared to indoor settings.

Methods. We conducted a systematic review of peer-reviewed papers indexed in PubMed, EMBASE, and Web of Science and preprints in Europe PMC through 12 August 2020 that described cases of human transmission of SARS-CoV-2. Reports of other respiratory virus transmission were included for reference.

Results. Five identified studies found a low proportion of reported global SARS-CoV-2 infections occurred outdoors (<10%) and the odds of indoor transmission was very high compared to outdoors (18.7 times; 95% confidence interval, 6.0–57.9). Five studies described influenza transmission outdoors and 2 adenovirus transmission outdoors. There was high heterogeneity in study quality and individual definitions of outdoor settings, which limited our ability to draw conclusions about outdoor transmission risks. In general, factors such as duration and frequency of personal contact, lack of personal protective equipment, and occasional indoor gathering during a largely outdoor experience were associated with outdoor reports of infection.

Conclusions. Existing evidence supports the wide-held belief that risk of SARS-CoV-2 transmission is lower outdoors but there are significant gaps in our understanding of specific pathways.

Keywords. coronaviruses; SARS-CoV-2; COVID-19; transmission; outdoor.

Recommendations about methods to curb transmission of severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) beyond wearing masks and maintaining social distance have varied, especially regarding outdoor transmission [1]. This variability reflects a general lack of information on how SARS-CoV-2 is transmitted outdoors.

Outdoor spaces generally allow for more physical distancing, which mitigates the risk of virus transmission through larger respiratory droplets [2]. Outdoor spaces allow for airflow, ventilation, and lack of recycled air, which all minimize the theoretical risk of aerosol transmission through smaller respiratory droplets. While aerosol spread in community settings is controversial, emerging data suggest that indoor recycled air can spread SARS-CoV-2—with examples of spreading events in a restaurant in Guangzhou [3], at an indoor choir practice in Skagit, Washington, United States [4], at a South Korean call center [5], at meat-packing plants in the United States [6], and in a nursing home in the Netherlands [7]. In areas with low ventilation, aerosolized droplets have the capacity to linger for longer before being inhaled or falling to a surface, which could result in fomite transmission [8]. In enclosed environments, low humidity, air conditioning, and low UV light may all contribute to longer survival of viral particles [9]. Outdoor environments also generally have fewer high-touch surfaces that may harbor the virus. UV light, present outdoors from sunlight, results in a 10-fold decrease in virus survival on surfaces [10]. Finally, indoor environments may increase host susceptibility; the low indoor humidity has been associated with slower host ciliary clearance and complications such as pneumonia, and lack of sunlight has been associated with lower vitamin D levels [11]. For these reasons, the risk of virus transmission in outdoor locations has been hypothesized to be lower than in indoor spaces.

We sought to quantify the risk of SAR-CoV-2 transmission in outdoor settings. We conducted a systematic review of the literature on transmission of SARS-CoV-2 to better understand the risks of outdoor transmission. Where data were available, we estimated the risk of outdoor compared to indoor transmission. Anticipating a paucity of data on SARS-CoV-2, we chose a broad search strategy that included other human betacoronaviruses and respiratory viruses.

METHODS

Search Strategy and Selection Criteria

Data for this review were identified by searches of PubMed, EMBASE, Web of Science, as well as preprints available in

Received 1 October 2020; editorial decision 23 November 2020; accepted 27 November 2020; published online November 29, 2020.

Europe PMC [12]. Details of our search strategies and eligibility criteria can be found in our protocol published on 3 August 2020 on PROSPERO (ID, 183826: www.crd.york.ac.uk/prospero/). The search was conducted on 17 June 2020, and because of the rapidly expanding data on SARS-CoV-2, the search was repeated to include most-recent literature on 12 August 2020.

Exposures and Outcomes

The exposure of interest—outdoor gatherings—was defined as persons congregating outdoors for work, social, or recreational activities (see Supplementary Material 1 for our full search strategy). The outcome of interest included cases of transmission of SARS-CoV-2 or other respiratory viruses identified by a case report, illness, or mortality. We also included secondary outcomes of clusters or outbreaks of cases. Our search included any viral infection that can be spread by respiratory droplets and, in addition to SARS-CoV-2, included the other 2 recognized human betacoronaviruses (SARS-CoV-1 and Middle east respiratory syndrome-CoV), human influenza viruses, adenoviruses, rhinoviruses, human metapneumoviruses, and respiratory syncytial virus.

We included studies (experimental or observational with empirical data collection) that described human-to-human transmission of respiratory viruses between humans in an outdoor setting, any review of these studies, and any study (experimental or observational) that compared respiratory viral transmission among humans in an outdoor versus indoor settings.

We excluded reviews of previously published data, studies of exclusively indoor outbreaks, outdoor outbreaks within animal populations or between animals and humans, and outbreaks where the site of transmission was not listed or was unclear. We also excluded studies limited to built environments (homes, apartment buildings, military barracks), hospitals, or forms of transportation (airplanes, trains, buses, cars, ships).

Data Selection and Extraction

After removing duplicate records, 1 author (T. C. B.) reviewed all downloaded citations based on their titles and prespecified inclusion criteria. A second author (M. M.) reviewed a 5% random sample of the excluded titles (rejected from initial search results) for quality control. Two authors (T. C. B. and N. R.) then independently screened the titles, abstracts, and descriptor terms and compared and discussed discrepancies until consensus was reached; a third author (M. M.) served as an arbiter when needed. Two authors (T. C. B. and N. R.) then independently inspected the full texts of the remaining studies for relevance based on exposure, design, and outcome measures to select the included papers, and discussed discrepancies until consensus was reached with a third author (M. M.) serving as arbiter. We used Endnote X9.3.2 (Clarivate Analytics) and Rayyan (Qatar Computing Research Institute, Doha, Qatar) web-based software to manage search results [13].

Two authors (T. C. B. and N. R.) extracted the following data from each paper into a prepiloted data extraction form in Excel spread sheets: complete citation, study location, study design, details of participants (risk group or groups, sample size), exposure details (type of gathering, characteristics of gathering place, number of people, duration, proportion of time spent outdoors, amount if any of indoor transmission, how the nonexposure state (indoors) was defined, outcomes (numerators and denominators associated with each outcome, definitions and descriptions of outcomes provided in papers, details of how outcomes were assessed, individual cases of infection and/or large spreading events, mortality), methodological details (sample characteristics, how the information was gathered, how the outbreak was investigated), and details related to bias assessment.

RESULTS

The combined searches yielded 10 912 unique citations, of which 12 studies met our inclusion criteria. Nine studies were identified from the 17 June 2020 search, 2 from the 12 August 2020, and 1 from a targeted search. Out of the 12 that met our inclusion criteria, 5 were pertaining to SARS-CoV-2 (Table 1 and Table 2), 5 reported on influenza or influenza-like viruses (Table 3), and 2 reported on adenovirus transmission. Of note, 33 studies were excluded because they did not specify the location of transmission (Supplementary Material 2). The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) diagram is shown in Figure 1.

Five studies related to SARS-CoV-2 transmission found that less than 10% of reported transmission occurred in outdoor settings, less than 5% of cases were related to outdoor occupations, and the odds of transmission or super-spreading are much lower outdoors (Table 1) [14–17].

Of 318 identified outbreaks involving 3 or more cases in China reported to local Municipal Health Commissions from 4 January to 11 February 2020, Qian et al found that all occurred in indoor environments [14]. They reported a single transmission that occurred outdoors (1 case of outdoor transmission out of 7324 total reported cases). This report, however, might be affected by strict interventions prohibiting mass gatherings outdoors, which likely contributed to the low number of cases contracted outdoors. Additionally, relying on local health department reports may have led to underestimates of the total number of transmissions, especially those that were asymptomatic [14].

Nishiura et al [16] analyzed the transmission pattern of coronavirus disease 2019 (COVID-19) reported through 28 February 2020 (11 clusters and sporadic cases) in Japan. They concluded that the odds of a primary case transmitting COVID-19 in a closed environment were 18.7 times greater (95% confidence interval [CI], 6.0–57.9) compared to outdoor setting (defined as an open-air environment). The odds of a single case spreading

Table 1. Comparison of Respiratory Virus Transmission Outdoors Compared to Indoors Ordered by Virus Studied

Outcome	Virus Studied	Estimate of Effect		Relative Estimate of Effect	Number of Participants in the Study
		Outdoor	Indoor		
Number of cases [14]	SARS-CoV-2	2/7324 cases	7322/7324 cases	<1% of transmissions happened outdoors	7324 cases, totaling 318 outbreaks
Number of cases [15]	SARS-CoV-2	4/103 cases	99/103 cases	5% of work-related cases occurred outdoors	103 possible work-related cases among a total of 690 local transmissions
Odds of transmission [16]	SARS-CoV-2	Raw data not available	Raw data not available	Odds of transmission in closed environments 18.7 (95% CI, 6.0–57.9) times greater than in open air	110 cases: 27 primary cases and 83 secondary cases
Number of super-spreading events and odds of transmission[a] [16]	SARS-CoV-2	1/7 super-spreading events	6/7 super-spreading events	Odds ratio of super-spreading in closed environments: 32.6 (95% CI, 3.7–289.5)	110 cases: 27 primary cases and 83 secondary cases
Number of cases [17]	SARS-CoV-2	95/10 926 cases	10 831/10 926 cases	<1% of transmissions happened outdoors	10 926 cases, totaling 201 events of transmission
Number of cases [18]	H1N1 2009 influenza	0/3 cases	24/29 cases	Of 32 total people in a holiday camp, 29 traveled together in a train wagon	32 people at a holiday camp
Mortality [19]	H1N1 1918 influenza	28/820 deaths sleeping in hammocks outside, 34.1 persons/1000	39/267 deaths sleeping in cabins inside, 146.1 persons/1000	Risk ratio 4.28 (95% CI, 2.69–6.81)	Total 1217 people on the ship

Abbreviations: CI, confidence interval; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2.

[a]Super-spreading defined as events where the number of secondary cases generated by a single primary case is greater than the 95th percentile of the distribution (ie, transmission to 3 or more persons).

to 3 or more individuals, which they defined as a super-spreader event, in closed environments compared to open air was 32.6 (95% CI, 3.7–289.5). This report, however, included no description of the context or location of the outdoor transmission nor were any raw data provided. It is unclear whether this report is relying on proportions, which again may be subject to the fact that fewer people would have been outdoors during winter months in Japan.

Leclerc et al [17] reviewed 201 transmission clusters of COVID-19 worldwide that had been reported up to 30 March 2020. The vast majority of these transmissions were associated with indoor or indoor/outdoor settings (197/201 clusters or 21/22 locations). The 1 outdoor setting was at multiple construction sites in Singapore, where 4 outbreaks occurred. Leclerc's updated results by August 12, from non-peer reviewed sources, additionally revealed one transmission occurred while jogging in Codogno, Italy, and twenty cases in an outdoor park in Münster, Germany (Table 4).

Lan et al [15] investigated 103 possible work-related cases of COVID-19 among a total of 690 local cases in 6 Asian countries or regions, including Hong Kong, Japan, Singapore, Taiwan, Thailand, and Vietnam. In this paper, construction workers in Singapore constituted only 5% of the total work-related transmissions. While this paper did not explicitly state whether the location of work-related transmission was outdoor or indoors, it was included based on Leclerc's classification of the same construction workers as an outdoor setting. This does not rule out that that transmission may have occurred in indoor locations at construction sites.

Szablewski et al [20] report SARS-CoV-2 transmission at an overnight camp in Georgia, United States, where attack rates increased with increasing length of time at the camp, and with cohousing. Staff members, who stayed the longest at the camp, had the highest attack rate (56%). The outbreak was clustered by cabin assignments, which suggests a high likelihood of transmission in indoor spaces during overnight cabin stays rather than during outdoor activities during the day. The authors state that nonpharmaceutical interventions such as cohorting and adults wearing masks during the day, were not protective, although no further information is given about this claim.

While there is high heterogeneity in the studies describing outdoor transmission of SARS-CoV-2, the studies we found highlight the conditions of outdoor exposure and transmission. The location and context of SARS-CoV-2 transmissions reported in this review are summarized in Table 4. Among these are examples of transmissions at a gathering in a park, but over multiple days with the same people, and at a camp, which lasted for several days and had indoor housing components.

Five other studies included in Table 3 describe outdoor transmission of influenza or influenza-like viruses. Summers et al [19] conducted a historical analysis of a large outbreak of the 1918 influenza virus on a military troop ship in July 1918. The outbreak involved over 1000 of the 1217 crew members and caused 68 deaths. Analysis of factors that might have contributed to

Table 2. Studies Reporting Outdoor SARS-CoV-2 Transmission

Reference	Location and Date	Sample Description	Design	Outcomes Measured	Outdoor Exposure	Outdoor Findings	Indoor Findings	Bias
Qian et al 2020 [14]	320 prefectural cities, China, 4 January to 11 February 2020	7324 cases, 318 outbreaks	Retrospective analysis of all public health reports from local Municipal Health Commission website to determine location of transmission	Location of transmissions, clusters, and outbreaks. Cluster defined as 3 or more infections that appear linked to the same infection venue. Outbreak defined as a cluster in which a common index patient is suspected. Outbreaks were organized by relationship and also by location.	Open air	One outdoor transmission involving 2 cases in Shangqiu, Henan: a 27-year-old man had a conversation outdoors with an individual who had returned from Wuhan	Of 318 identified outbreaks that involved 3 or more cases, they all occurred in indoor environments	Relied on heterogenous case reports of the local health department, which might have missed cases because of differential allocation of resources or internal biases. Additionally, the data were collected partly after lockdown (started 23 January 2020 in Wuhan), after which most people were indoors.
Nishiura et al 2020 [16]	7 prefectures in Japan, start date 28 February 2020	110 cases (27 primary cases, 83 secondary cases); 7 super-spreading events identified	Retrospective case investigation using contact tracing data	Location and number of transmissions from primary to secondary cases. Super-spreading events defined as number of secondary cases generated by a single primary case is greater than the 95th percentile of the distribution (ie, transmission to 3 or more persons)	Open air	Odds of transmission in a closed environment was 18.7 times greater compared to an open-air environment (95% CI, 6.0–57.9). Odds ratio of super-spreading events in closed environments was as high as 32.6 (95% CI, 3.7–289.5). One super-spreading event occurred outdoors (not described).	Of 7 super-spreading events, 6 (85.7%) took place in closed environments	Small sample size and no raw data provided to support calculations of odds. Limitations were not discussed in the manuscript. Not peer-reviewed at the time of review.
Leclerc et al 2020 [17]	Multiple world-wide locations, as of 30 March 2020	201 events of transmission (clusters)	Review of all documented transmission clusters (world-wide) using literature review and open-source strategies	Settings of transmission clusters for 201 events	22 types of settings were determined. Outdoor locations were defined as outdoor, while locations that were a mixture were defined as indoor/outdoor. Indoor locations were defined as indoor.	The transmissions in the only outdoor setting occurred in 4 outbreaks at outdoor construction sites in Singapore, totaling 95 cases. Updated results additionally revealed 1 transmission occurred while jogging in Codogno, Italy (nonpeer reviewed source) and 20 cases in an outdoor park in Münster, Germany (nonpeer reviewed source)	10/22 locations defined as indoor/outdoor, 11/ 22 defined as indoor. Total 197 events occurred in these settings, totaling 10 831 cases	Included reports from some nonpeer reviewed sources (eg. local media outlets for the jogging and outdoor park transmission reports), which might have been individually influenced by recall bias and poor methodology. While the study conducted a systematic review, additional sources were collected using an open-source strategy, which might have been affected by selection bias of respondents.

Table 2. Continued

Reference	Location and Date	Sample Description	Design	Outcomes Measured	Outdoor Exposure	Outdoor Findings	Indoor Findings	Bias
Lan et al 2020 [15]	6 Asian regions: Hong Kong, Japan, Singapore, Taiwan, Thailand, and Vietnam, 23 January–14 March 2020	690 locally transmitted cases	Observational study, extracted confirmed COVID-19 cases from governmental investigation reports. Only locally transmitted (nonimported) cases were included. Transmission period was extended to 40 d from primary case.	Number of cases per occupation across country/area and stratified into early (first 10 d) and late (11-40 d) transmission periods	Workplace largely outdoors	A total of 103 possible work-related cases were determined to be outdoors among a total of 690 local transmissions. Of workers that might be prevalently outdoors, 5% of cases were construction workers. Tour guides (5% of cases) might also be considered to have occurred partly outdoors.	The 5 occupation groups with the most cases were health care workers (22%), drivers and transport workers (18%), services and sales workers (18%), cleaning and domestic workers (9%), and public safety workers (7%).	The exact outdoor/indoor makeup of the location of transmission was not described. This is in part due to the fact that the transmission source was not always known, and detailed occupational histories were also not always known. Also, none of the reports arose from systematic testing of high-risk occupations, rather from individual case reports, which might have been affected by biased and heterogenous reporting mechanisms from different regions.
Szablewski et al 2020 [20]	Overnight camp in Georgia, United States, 17–27 June 2020	During 17–20 June the overnight camp held orientation for 138 trainees and 120 staff members; staff members remained for the first camp session, scheduled 21–27 June, and were joined by 363 campers and 3 senior staff members on 21 June. Children and adults attended.	Retrospective case investigation (MMWR)	Positive test result for SARS-CoV-2 (symptomatic and asymptomatic)	Camp attendees were cohorted by cabin and engaged in a variety of indoor and outdoor activities, including daily vigorous singing and cheering	On 24 June a staff member tested positive to SARS-CoV-2. Test results were later available for 344 attendees; among these, 260 (76%) were positive. The percentage of transmission that developed solely outdoors was not investigated.	Median cabin attack rate was 50% among 28 cabins that had 1 or more cases (on average, each cabin housed 15 people). Attack rate was highest in the larger cabin, suggesting the main location of transmission was in the cabins.	Attack rates are likely an underestimate because cases might have been missed among persons not tested or whose test results were not reported. Some cases may have resulted from transmission occurring before or after camp attendance. Exact details of outdoor activities versus indoor were not described.

Abbreviations: CI, confidence interval; COVID-19, coronavirus disease 2019; MMWR, Morbidity and Mortality Weekly Report; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2.

Downloaded from https://academic.oup.com/jid/advance-article/doi/10.1093/infdis/jiaa742/6009483 by guest on 21 February 2021

Table 3. Studies Reporting Other Outdoor Respiratory Virus Transmission Ordered by Infection Identified

Reference	Virus	Location and Date	Sample Description	Design	Outcomes Measured	Outdoor Exposure	Outdoor Findings	Indoor Findings	Bias
Figueroa et al 2017 [22]	Respiratory disease outbreaks	United States, 2009–2014	18 mass gatherings in 8 states	Data were collected on mass-gathering–related respiratory disease outcomes; 50 state health departments and 31 large local health departments were contacted via online assessment; 43 (53%) of 81 health jurisdictions responded	Outbreak was defined as 1 or more cases of an infectious respiratory disease. Mass gathering (exposure) was defined as a planned or unplanned congregation of 1000 or more persons in either an indoor or outdoor venue for a common purpose.	Mass gatherings were defined as indoors or indoor/outdoors	All reported outbreaks occurred at multiday mass gathering events. For influenza A (H1N1) attack rates at 2 summer camps were 1.4% and 4.8%. Attack rate for a religious event was 19.5%. At a sporting event in the spring, it was 3.3% but only included athletes. Attack rate of influenza A (H3) at another summer camp was 0.02%.	At a professional conference in the winter, which was likely to be mostly indoors, attack rate was of 21.0%. Probable factors that affected attack rates were participant density and susceptibility, rather than gathering size alone. Use of nonpharmaceutical interventions might have been an additional factor.	Low response rate (around 50%) by state health departments, while there was no response from local health departments. There might be responder bias, given that departments that experienced mass gathering outbreaks might have been more willing to respond. Details of each mass gathering and their indoor/outdoor locations are not described.
Rainey et al 2016 [21]	Respiratory disease outbreaks	United States, 2005–2014	21 published articles describing 72 mass-gathering–related respiratory disease outbreaks. 1114 outbreaks reported to NORS	6 medical, behavioral, and social science literature databases were analyzed to extract relevant articles. NORS was also analyzed to estimate the frequency of mass-gathering–related respiratory disease outbreaks.	Mass gatherings were defined as large events involving more than 1000 persons in a specific location for a shared purpose. Definition of outbreak was deferred to the author's definition. Half of the reported outbreaks were related to a zoonotic source and were excluded. 38% of the outbreaks occurred at a variety of camps.	The authors did not specify outdoor vs indoor location of mass gathering	Close social mixing and contact in communal housing/activities were associated with all other outbreaks identified. They concluded that multiday mass gatherings with indoor residential overnight components can facilitate transmission.	All reported outbreaks in summer camps had social contact and communal housing, none reported without a housing component	Search strategy might have not captured studies that did not use the word outbreak, and might have missed any outbreak not captured by surveillance systems (eg. smaller outbreaks, of diseases with longer incubation periods). While indoor and outdoor characteristics of mass gatherings were discussed, exact amount of time spent outdoors compared to indoors not delineated.
Botelho-Nevers et al 2013 [23]	Disease outbreaks (including respiratory disease)	Open-air mass gatherings worldwide, 1980–2012	9 published articles about respiratory infections at large, outdoor mass gatherings, festivals, or music festivals	Literature search using PubMed and MEDLINE database, with cross-referencing using search engines such as Google and Yahoo	Outbreaks in the setting of open-air gatherings	Mass gatherings defined as generally outdoors, but which may have onsite indoor housing and food supply	4 outbreaks of influenza A (H1N1) and 1 of influenza A and B were found. Overall, the estimated incidence of confirmed respiratory infections of influenza per 100 000 attendees ranged from 2 to 30. The discrepancy between sport events, which seem to have lower incidence, and large-scale open-air festivals in terms of infectious diseases may also be the consequence of the relatively short duration of sports events, which frequently last shorter than 1 day.	No exclusively indoor events were included	The infections related to large open-air festivals may be underreported, given difficulty in ascertaining exact location of transmission and sporadic surveillance systems. The search strategy of only using ProMed and MEDLINE might have limited the amounts of results that might otherwise be available on other reporting/surveillance agencies.

Table 3. Continued

Reference	Virus	Location and Date	Sample Description	Design	Outcomes Measured	Outdoor Exposure	Outdoor Findings	Indoor Findings	Bias
Pestre et al 2012 [18]	2009 H1N1 Influenza	Summer camp in France, August 2009	32 persons participated in the holiday camp; 29 of them traveled in the same train wagon	Retrospective case investigation	Infection of H1N1 influenza	Individuals who did not travel in the same train wagon	The outbreak involved 21 children and 3 adults who had all travelled together in the same wagon. The 3 individuals that did not take the same train wagon and were immediately thereafter in contact with the 24 infected individuals at camp did not experience influenza symptoms.	Out of 29 individuals who took the same train wagon, 21 children and 3 adults experienced symptoms	Conditions of outdoor versus indoor activities at camp were not described. Given this, the comparison between indoor (train wagon) and outdoor (camp) exposure assumes that a majority of time at camp, as compared to the train wagon, was outdoors. Measurement of cases might have been affected by timing of testing and/or presence of asymptomatic cases. Limitations were not discussed.
Summers et al 2010 [19]	1918 Influenza	His Majesty's New Zealand Transport military troop ship in Sierra Leone, July 1918	1217 persons onboard	Retrospective historical outbreak analysis	Mortality	Sleeping in hammocks as opposed to cabins with bunks	Of 1217 persons onboard, over 1000 suspected cases of influenza, 68 deaths. Mortality rate for persons that slept in hammocks outdoors was 28/820 or 34.1 persons/1000 population.	Mortality rate for persons that slept in cabins with bunks was 39/267 (146.1 persons/1000 population). The difference between hammocks was significant (crude RR, 4.28; 95% CI, 2.69–6.81). Density did not seem to be a contributing factor.	Historical evidence used in this paper is subject to transcription and/or recording errors, lack of case definitions, and approximate estimates of case numbers. While it is hinted that hammocks were in higher ventilated zones outdoors as compared to cabins, the exact location of hammocks was not described.

Abbreviations: CI, confidence interval; NORS, National Outbreaks Reporting System; RR, relative risk.

Downloaded from https://academic.oup.com/jid/advance-article/doi/10.1093/infdis/jiaa742/6009483 by guest on 21 February 2021

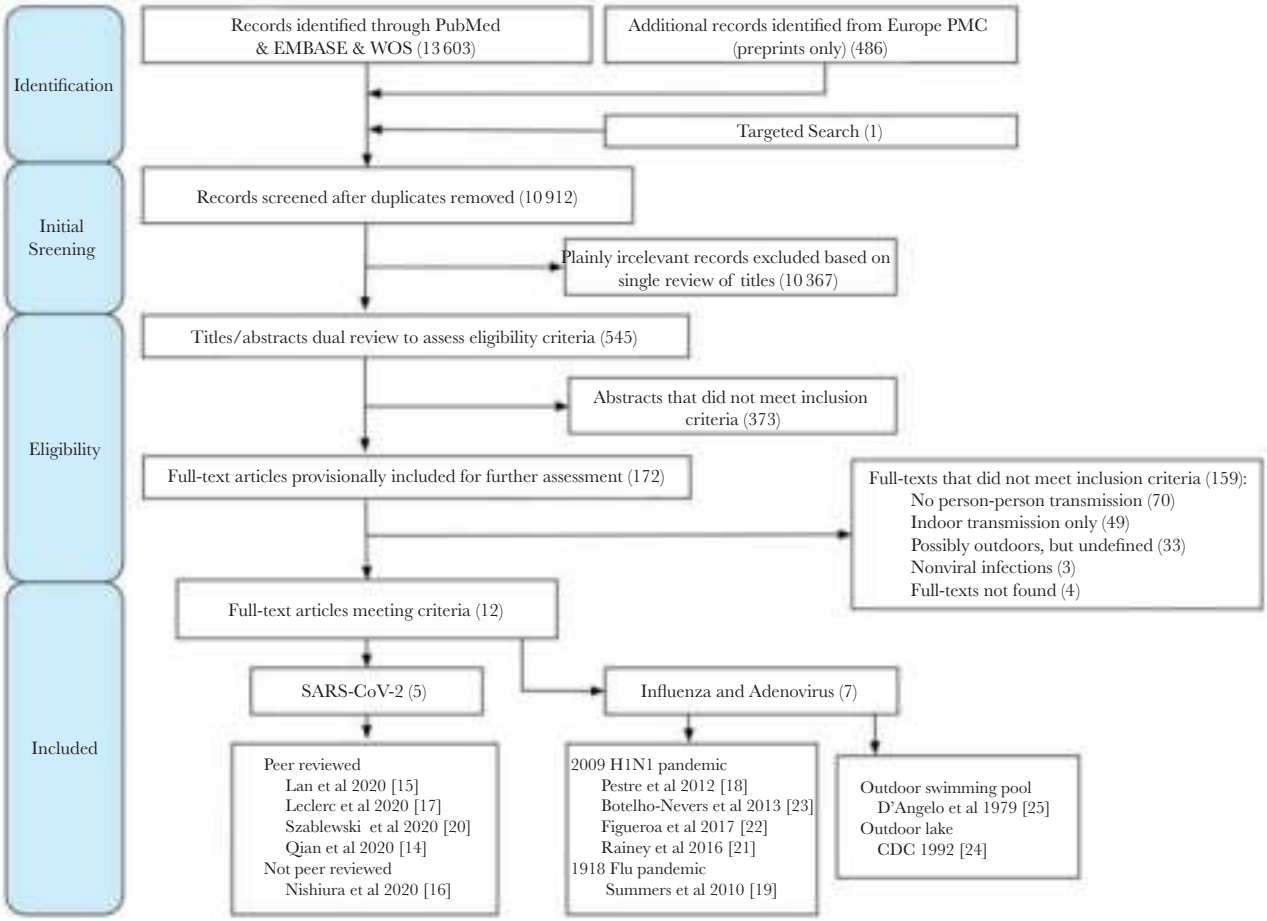

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) diagram for the study. Abbreviations: CDC, Centers for Disease Control and Prevention; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2; WOS, Web of Science.

mortality revealed a significant association between individuals who slept indoors, in cabins with bunks (mortality of 146.1/1000 population), versus individuals who slept in hammocks in open-air areas (mortality of 34.1/1000 population). This study is of particular interest because the duration of exposure and distance between individuals was held constant. This was one of the few studies that investigated potential confounders such as age and social class—mortality changed with age, but not with social class or rurality. Age did not change the discrepancy in deaths seen outdoors compared to indoors.

Pestre et al [18] conducted a retrospective analysis of a 2009 H1N1 influenza outbreak at a summer camp in France. Investigations revealed that all febrile individuals had travelled together in the same train passenger car to reach camp, suggesting that the enclosed space facilitated transmission. The 3 individuals out of 32 that had not travelled in the same train wagon as all the other participants never developed symptoms, even though they were still present at camp for 2 days with all other infected individuals—presumably mostly in outdoor spaces.

Finally, 3 reports about respiratory illnesses at mass open-air gatherings emphasized that while influenza outbreaks were uncommon, the duration of the event (multiday over single day) and communal housing were risk factors for outbreaks (Table 3) [21–23]. Rainey et al concluded that all reported outbreaks in summer camps had social contact and communal housing; none were reported without a shared housing component [21]. Of note, no single-day mass-gathering–related outbreaks were detected in the 72 outbreaks they detail. Figueroa et al also did not identify any single-day event-related outbreaks [22]. Botelho et al found 4 outbreaks of influenza A (H1N1) and 1 of influenza A and B; all events with an outbreak were multiday sport events while single-day events had none [23].

Two articles discussed adenovirus outbreaks associated with lakes [24] and outdoor swimming pools [25]. In both studies respiratory viral infection occurred in swimmers and in others who did not swim, such as fellow camp attendees and family members, suggesting human-to-human transmission prevalently occurring outdoors.

Table 4. Outdoor Conditions Where COVID-19 Was Transmitted

Setting	Description of Transmission	Purely Outdoors?	Use of Nonpharmaceutical Interventions[a]
Overnight summer camp [20]	Outbreak of 260 cases during an overnight camp in Georgia. Everyone tested negative for COVID-19 ≤12 days prior to coming to camp. While exact outdoor activities were not described, the overnight component suggests that the attack rate increased with length of time spent at the camp. This was shown by staff members, who were present at camp the longest, having the highest attack rate (56%). Attack rate associated with being adult, length of stay, and being in a cabin together. Median attack rate in the cabins, 50%; overall attack rate, 44%.	No	Yes. They state the NPI was not effective. NPIs were cohorting of attendees by cabin (≤ 26 persons), staggering of cohorts for use of communal spaces, physical distancing outside cabin cohorts, and enhanced cleaning and disinfection, especially of shared equipment and spaces. Cloth masks were required for staff members. Evidently, these interventions were not effective at preventing a majority of cases.
Conversation in outdoor setting [14]	One outdoor transmission involving 2 cases in Shangqiu, Henan: a 27-year-old man had a conversation outdoors with an individual who had returned from Wuhan. No secondary or tertiary cases from this transmission were reported	Yes	Unknown
Outdoor construction sites [15, 17]	Four outbreaks at outdoor construction sites in Singapore, involving a total of 95 cases [17]. 5 cases of construction workers in Singapore [15]. Details of exact location of transmission were not described. Details of indoors versus outdoors unknown. However, in Leclerc et al [17] building sites were described as outdoor settings.	Unknown	Unknown
Jogging outdoors [17]	1 transmission while jogging in Codogno, Italy (reported by local news media, cited in Leclerc et al [17] open source database)	Yes	Unknown
Outdoor park [17]	20 cases in an outdoor park in Münster, Germany (reported by local news media, cited in Leclerc et al [17] open source database). The members of the extended family, who had been living in different houses in the Angelmodde district of Munster, were suspected to have met often on a playground in the Osthuesheide district. The activities of the family were not described, but it was described as a repeated exposure over days.	Yes	Unknown

Abbreviations: COVID-19 coronavirus disease 2019; NPI, nonpharmaceutical intervention.
[a]Such as masks, physical distance, cohorting.

DISCUSSION

While the studies included in this review were highly heterogeneous, ranging in methodology, definition of outdoor transmission, and virus studied, several common factors were identified. The studies with direct comparison of SARS-CoV-2 location of transmission reported dramatically lower proportions occurring outdoors. The exact determinants of outdoor transmission that can be gleaned from this review are limited, the cases of outdoor transmission of SARS-CoV-2 we identified were affected by the duration of exposure, frequency of exposure, density of gathering, whether masks were used, and were confounded by the possibility of indoor transmission.

Historical evidence gleaned from influenza outbreaks further support the lower risk of transmission outdoors. Summers et al showed that influenza mortality on a ship was significantly lower outdoors (sleeping in hammocks) compared to indoors (sleeping in cabins) [19]. While mortality does not provide direct information about transmission, it serves as a useful proxy. Outcomes from several investigations of influenza outbreaks during mass outdoor gatherings suggest that outdoor, single-day events without communal sleeping arrangements have lower risks of influenza transmission than multiday events with indoor components [21–23].

These findings, as well as reports of influenza outbreaks and adenovirus outbreaks in outdoor bodies of water, suggest that while outdoor transmission is less common than indoor, it is not impossible. Case reports identified after our review had been completed provide further evidence that high-density outdoor gatherings, particularly with low mask use, may lead to higher transmission rates. Miron et al noted that incidence of COVID-19 cases was significantly higher in 14 out of 20 counties that had a large outdoor gathering 15 days prior [26]. Dave et al estimated that in the 3 weeks following the start of the Sturgis motorcycle rally on 7 August 2020, in South Dakota, a multiday event with 500 000 participants, cases grew more in counties with weak mitigation policies than those with strong mitigation policies (such as closure of restaurants and bars, or mask-wearing mandates) as participants returned to their homes [27]. In contrast, although COVID-19 rates increased in the 3 weeks following the mass protests in the United States [28], the uptick in cases due to these events was less than expected because social distancing and masking measures were more widespread [29]. The importance of protective measures is further exemplified by the outdoor outbreak that occurred at the White House Rose Garden event on 26 September 2020, where few of the 200 attendees were wearing masks or maintaining social distancing measures [30].

Of note, our search did not find any studies on the transmission of COVID-19 in settings of outdoor agricultural work. In California, prevalence of COVID-19 for agricultural workers is 2 to 3 times higher than the rate for workers in all other industries [31]. The experience of agricultural workers suggests

Downloaded from https://academic.oup.com/jid/advance-article/doi/10.1093/infdis/jiaa742/6009483 by guest on 21 February 2021

that crowded working or sleeping conditions may be a substantive risk factor for transmission, but the contribution of work in outdoor spaces to transmission risk has not been assessed. We found that outdoor, single-day events without communal sleeping arrangements have lower risks of transmission compared to multiday, mass outdoor gatherings in the spread of influenza [21–23].

To better characterize the risks of outdoor SARS-CoV-2 exposure, future studies should fill the research gaps we have identified in this review. First, many research studies we identified did not report the location of transmission at all. This may be because understanding relationships between cases is more important than the location of interaction, or may be related to practical challenges in contact tracing outdoors. Second, it is difficult to isolate an outdoor exposure to a virus. While outdoor gatherings could be largely safe, if they are accompanied by time in indoor locations, such as cabins or trains, it might be challenging to identify the exact location of transmission. In the report by Szablewski et al, which was included in our review, while the summer camp may have been largely outdoors, it does not preclude exposure in the dining halls or cabins. As for construction sites, once a building is framed and enclosed, it may be considered indoor work, which may in fact be the majority of the work. Third, in many reports published early in the SARS-CoV-2 pandemic, the measured outcome was illness or death due to viral infection, not SARS-CoV-2 infection itself, which was rarely assessed. If asymptomatic infections are more likely to occur outdoors, this could represent a systematic bias. Fourth, the definition of being outdoors is ambiguous, and the effect of exposure is likely modified by variable proximity to and contact with others. Fifth, to test the hypothesis that the risk of infection is lower outdoors, future research should collect data about time spent indoors versus outdoors. Given that 90% of time is spent indoors in high- and middle-income countries [32], it would be expected that 90% of transmission occurs indoors, all else being equal. Lastly, there are few data that examine how respiratory droplets spread outdoors, such as how far they travel during running, biking, or during windy conditions. A study examined these variables but was calculated with no account of ventilation, sunlight, or humidity [33].

Finally, most of the transmission events we identified in the literature did not report the socioeconomic status of those impacted. Spreading events often occur in settings where marginalized and disempowered populations live or work such as lower-income, higher-density urban settings, work settings such as meat-packing plants, or even prisons [34]. While there are multiple reasons for the disproportionate impacts of COVID-19 in these populations, we postulate that lack of opportunity to move high-risk activities outdoors may be one of them [35, 36]. While it was our intention to further explore this hypothesis by analyzing subgroup socioeconomic and ethnicity data in the studies included in this review, the studies did not include these metrics.

Future studies could compare SARS-CoV-2 case rates at outdoor gatherings to known rates for indoor gatherings. There are several examples of studies that estimate the risk of indoor transmission [37–39], which have ranged from 10.3% (95% CI, 5.3%–19.0%) in a study of train travel in China to 78% in a church in Arkansas [38]. Accurate estimation of the risk of outdoor transmission will require determining person-time at risk for infection, incidence rate ratios, and more nuanced information about the exposure environment; these data are still lacking.

Better understanding of how SARS-CoV-2 is transmitted outdoors is needed to inform sound policies that reconcile shelter-in-place orders with the many health benefits associated with time spent outdoors [40]. This is particularly relevant to outdoor parks and recreation agencies, which seek clear guidance on how being outdoors has a low risk of transmission. Other policy implications are to encourage moving essential activities outdoors, with appropriate masking and social distancing measures, given that transmission can still occur outdoors. The long-term and potentially deleterious social and emotional effects of school closures can be potentially mitigated if, for example, it is known that outdoor schooling is a viable alternative. Finally, encouraging outdoor time may serve as a harm reduction model in allowing people to congregate, and therefore better tolerate long-term shelter in place mandates.

This systematic review has several limitations. The few and heterogenous studies on outdoor transmission of respiratory viruses had used various metrics, exposures, and outcomes, making it challenging to compare findings quantitatively. The low proportion of outdoor COVID-19 cases may reflect the general decrease in outdoor activities since strict lockdowns were enacted in the countries surveyed. Relying on reports of symptomatic infections may underrepresent asymptomatic cases that occur outdoors. If the viral inoculum affects the severity of respiratory viral infection, an outdoor exposure may reduce the viral inoculum to which the individual is exposed and therefore the subsequent clinical impact of the disease. If this theory were true for SARS-CoV-2, it may increase the proportion of infections that are asymptomatic [41]. The studies in this review did not contain much information about potential confounders such as the age of infected individuals, activities in which they participated, ethnicity, or social class. There was minimal information on mitigation efforts such as masks and social distancing and how that may have impacted/influenced viral transmission. This review did not explicitly include gray literature (such as case reports from health departments, lay newspaper sources) in its search strategy, as other comprehensive reviews of transmissions have done [17]. Including preprints may have decreased our risk of information bias.

CONCLUSION

While it has been acknowledged that spending time outside has general health benefits, our review posits that there are also benefits in reducing transmission of SARS-CoV-2 by reducing exposure time (substituting time indoors with time outdoors). These results suggest that moving activities to outdoor settings may reduce infections and ultimately save lives. However, it is important to note that infections are possible outdoors and the advantage may be overtaken by relaxed mitigation efforts.

Supplementary Data

Supplementary materials are available at *The Journal of Infectious Diseases* online. I. The Mission

Goal and Objectives

The overall goal of the Joint Mission was to rapidly inform national (China) and international planning on next steps in the response to the ongoing outbreak of the novel coronavirus disease (COVID-19[1]) and on next steps in readiness and preparedness for geographic areas not yet affected.

The major objectives of the Joint Mission were as follows:

- To enhance understanding of the evolving COVID-19 outbreak in China and the nature and impact of ongoing containment measures;
- To share knowledge on COVID-19 response and preparedness measures being implemented in countries affected by or at risk of importations of COVID-19;
- To generate recommendations for adjusting COVID-19 containment and response measures in China and internationally; and
- To establish priorities for a collaborative programme of work, research and development to address critical gaps in knowledge and response and readiness tools and activities.

Members & Method of Work

The Joint Mission consisted of 25 national and international experts from China, Germany, Japan, Korea, Nigeria, Russia, Singapore, the United States of America and the World Health Organization (WHO). The Joint Mission was headed by Dr Bruce Aylward of WHO and Dr Wannian Liang of the People's Republic of China. The full list of members and their affiliations is available in Annex A. The Joint Mission was implemented over a 9-day period from 16-24 February 2020. The schedule of work is available in Annex B.

The Joint Mission began with a detailed workshop with representatives of all of the principal ministries that are leading and/or contributing to the response in China through the National Prevention and Control Task Force. A series of in-depth meetings were then conducted with national level institutions responsible for the management, implementation and evaluation of the response, particularly the National Health Commission and the China Centers for Disease Control and Prevention (China CDC). To gain first-hand knowledge on the field level implementation and impact of the national and local response strategy, under a range of epidemiologic and provincial contexts, visits were conducted to Beijing Municipality and the provinces of Sichuan (Chengdu), Guangdong (Guangzhou, Shenzhen) and Hubei (Wuhan). The field visits included community centers and health clinics, country/district hospitals, COVID-19 designated hospitals, transportations hubs (air, rail, road), a wet market, pharmaceutical and personal protective equipment (PPE) stocks warehouses, research institutions, provincial health commissions, and local Centers for

[1] In the Chinese version of this report, COVID-19 is referred to throughout as novel coronavirus pneumonia or NCP, the term by which COVID-19 is most widely known in the People's Republic of China.

Disease Control (provincial and prefecture). During these visits, the team had detailed discussion and consultations with Provincial Governors, municipal Mayors, their emergency operations teams, senior scientists, frontline clinical, public health and community workers, and community neighbourhood administrators. The Joint Mission concluded with working sessions to consolidate findings, generate conclusions and propose suggested actions.

To achieve its goal, the Joint Mission gave particular focus to addressing key questions related to the natural history and severity of COVID-19, the transmission dynamics of the COVID-19 virus in different settings, and the impact of ongoing response measures in areas of high (community level), moderate (clusters) and low (sporadic cases or no cases) transmission.

The findings in this report are based on the Joint Mission's review of national and local governmental reports, discussions on control and prevention measures with national and local experts and response teams, and observations made and insights gained during site visits. The figures have been produced using information and data collected during site visits and with the agreement of the relevant groups. References are available for any information in this report that has already been published in journals.

The final report of the Joint Mission was submitted on 28 February 2020.

II. Major findings

The major findings are described in six sections: the virus, the outbreak, transmission dynamics, disease progression and severity, the China response and knowledge gaps. More detailed descriptions of technical findings are provided in Annex C.

The virus

On 30 December 2019, three bronchoalveolar lavage samples were collected from a patient with pneumonia of unknown etiology – a surveillance definition established following the SARS outbreak of 2002-2003 – in Wuhan Jinyintan Hospital. Real-time PCR (RT-PCR) assays on these samples were positive for pan-Betacoronavirus. Using Illumina and nanopore sequencing, the whole genome sequences of the virus were acquired. Bioinformatic analyses indicated that the virus had features typical of the coronavirus family and belonged to the Betacoronavirus 2B lineage. Alignment of the full-length genome sequence of the COVID-19 virus and other available genomes of Betacoronavirus showed the closest relationship was with the bat SARS-like coronavirus strain BatCov RaTG13, identity 96%.

Virus isolation was conducted with various cell lines, such as human airway epithelial cells, Vero E6, and Huh-7. Cytopathic effects (CPE) were observed 96 hours after inoculation. Typical crown-like particles were observed under transmission electron microscope (TEM) with negative staining. The cellular infectivity of the isolated viruses could be completely neutralized by the sera collected from convalescent patients. Transgenic human ACE2 mice and Rhesus monkey intranasally challenged by this virus isolate induced multifocal pneumonia with interstitial hyperplasia. The COVID-19 virus was subsequently detected and isolated in the lung and intestinal tissues of the challenged animals.

Whole genome sequencing analysis of 104 strains of the COVID-19 virus isolated from patients in different localities with symptom onset between the end of December 2019 and mid-February 2020 showed 99.9% homology, without significant mutation (Figure 1).

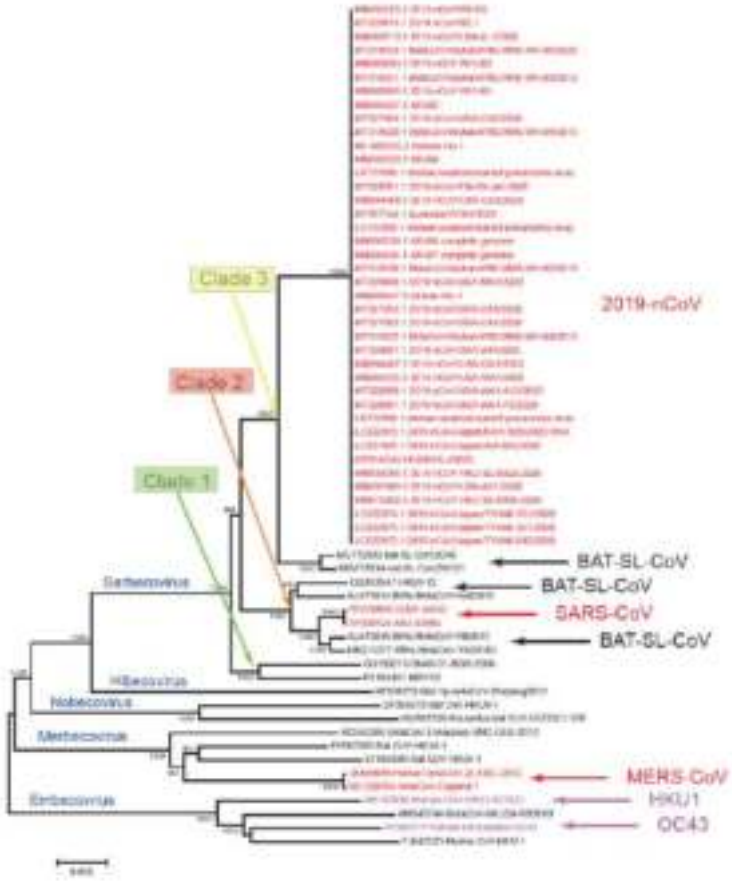

Figure 1. Phylogenetic analysis of the COVID-19 virus and its closely related reference genomes

Note: COVID-19 virus is referred to as 2019-nCoV in the figure, the interim virus name WHO announced early in the outbreak.

Post-mortem samples from a 50-year old male patient from Wuhan were taken from the lung, liver, and heart. Histological examination showed bilateral diffuse alveolar damage with cellular fibromyxoid exudates. The lung showed evident desquamation of pneumocytes and hyaline membrane formation, indicating acute respiratory distress syndrome (ARDS). Lung tissue also displayed cellular and fibromyxoid exudation, desquamation of pneumocytes and pulmonary oedema. Interstitial mononuclear inflammatory infiltrates, dominated by lymphocytes, were seen in both lungs. Multinucleated syncytial cells with atypical enlarged pneumocytes characterized by large nuclei, amphophilic granular cytoplasm, and prominent nucleoli were identified in the intra-alveolar spaces, showing viral cytopathic-like changes. No obvious intranuclear or intracytoplasmic viral inclusions were identified.

The outbreak

As of 20 February 2020, a cumulative total of 75,465 COVID-19 cases were reported in China. Reported cases are based on the National Reporting System (NRS) between the

National and Provincial Health Commissions. The NRS issues daily reports of newly recorded confirmed cases, deaths, suspected cases, and contacts. A daily report is provided by each province at 0300hr in which they report cases from the previous day.

The epidemic curves presented in Figures 2 and 3 are generated using China's National Infectious Disease Information System (IDIS), which requires each COVID-19 case to be reported electronically by the responsible doctor as soon as a case has been diagnosed. It includes cases that are reported as asymptomatic and data are updated in real time. Individual case reporting forms are downloaded after 2400hr daily. Epidemiologic curves for Wuhan, Hubei (outside of Wuhan), China (outside Hubei) and China by symptom onset are provided in Figure 2.

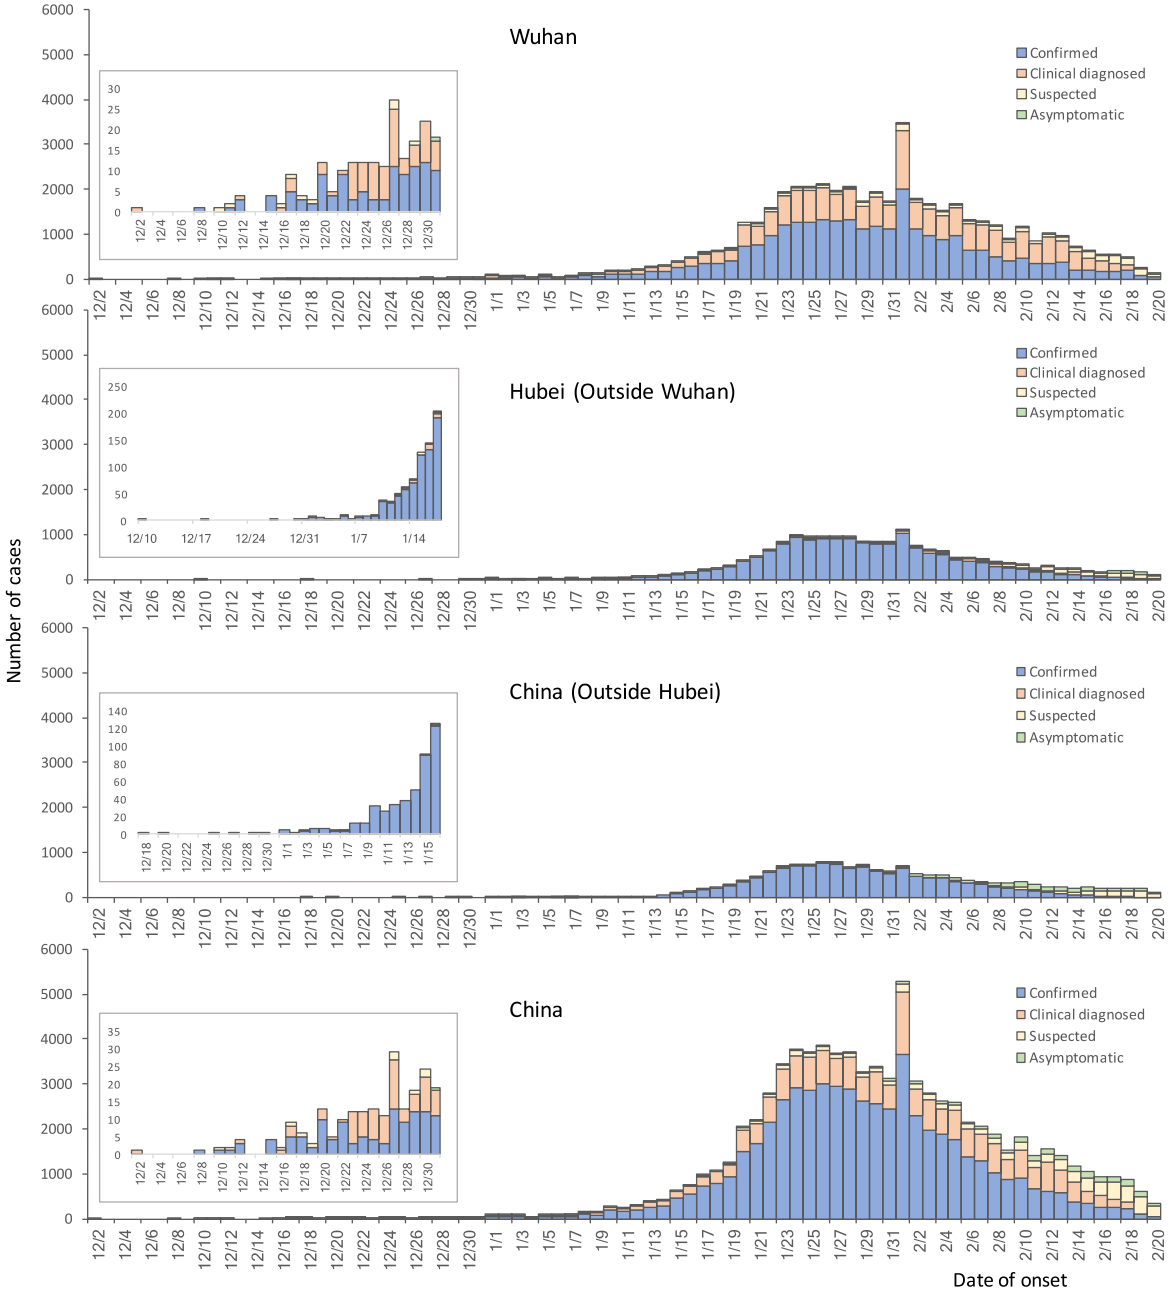

Figure 2 Epidemiologic curve of COVID-19 laboratory confirmed cases, by date of onset of illness, reported in China, as of 20 February 2020

Figure 3 presents epidemic curves of laboratory-confirmed cases, by symptom onset and separately by date of report, at 5, 12, and 20 February 2020. Figures 2 and 3 illustrate that the epidemic rapidly grew from 10-22 January, reported cases peaked and plateaued between 23 January and 27 January, and have been steadily declining since then, apart from the spike that was reported on 1 February (note: at a major hospital in Wuhan, fever clinic patients fell from a peak of 500/day in late January to average 50/day since mid-February).

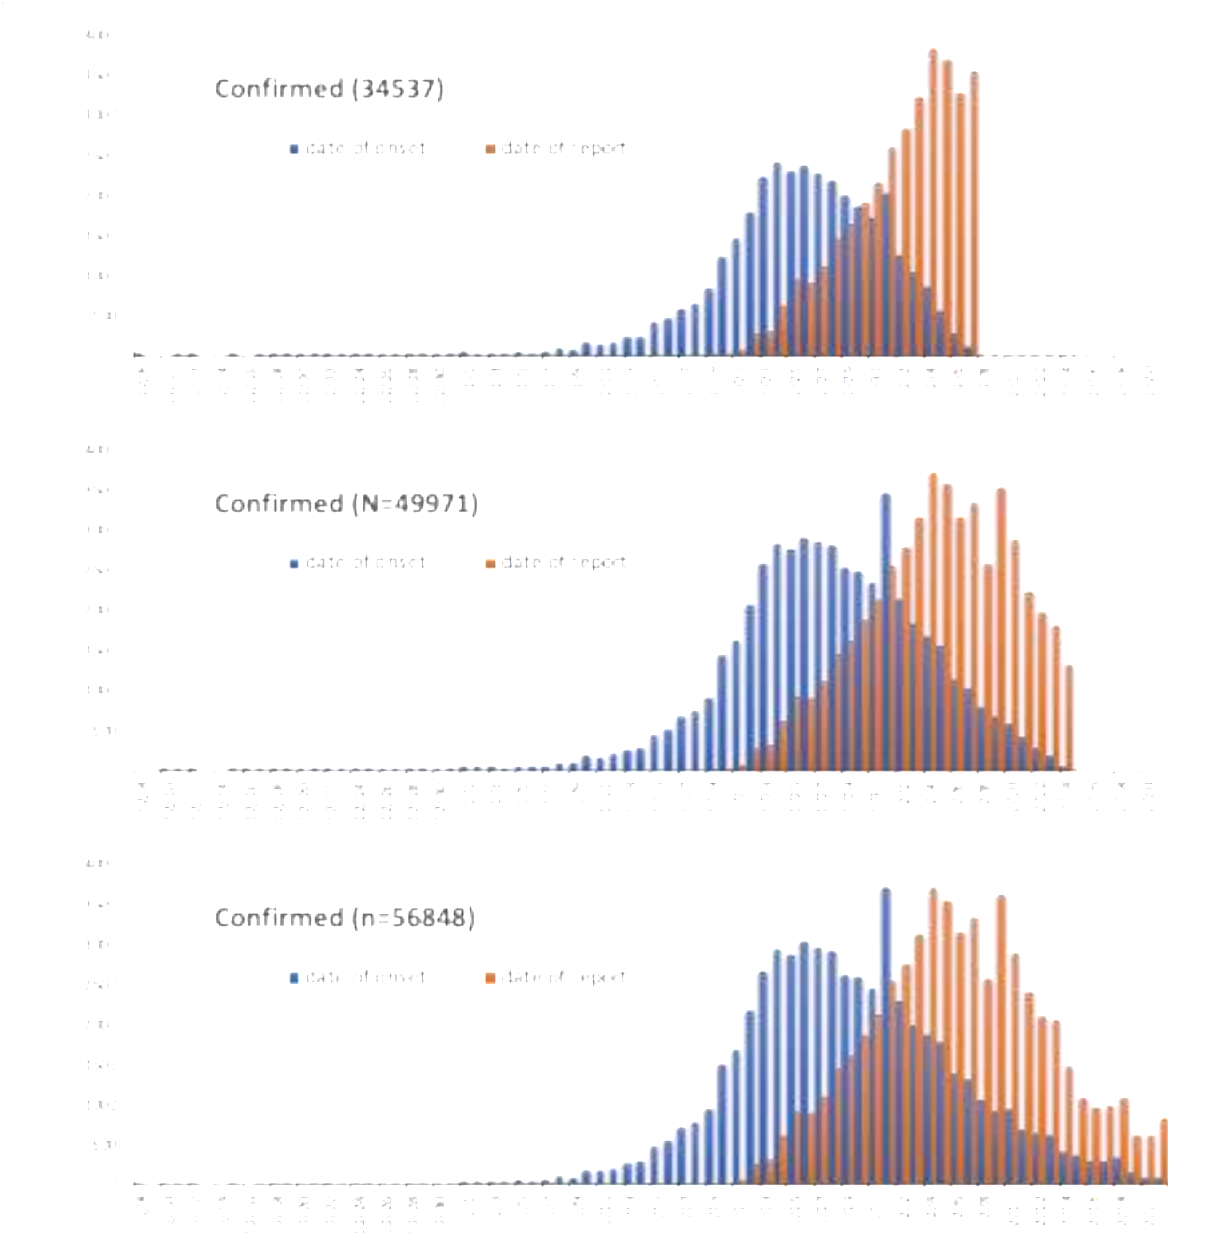

Figure 3. Epidemic curves by symptom onset and date of report as of 5 February (top panel), 12 February (middle panel) and 20 February 2020 (lower panel) for laboratory confirmed COVID-19 cases for all of China

Based on these epidemic curves, the published literature, and our on-site visits in Wuhan (Hubei), Guangdong (Shenzhen and Guangzhou), Sichuan (Chengdu), and Beijing, the Joint Mission team has made the following epidemiological observations:

Demographic characteristics

Among 55,924 laboratory confirmed cases reported as of 20 February 2020, the median age is 51 years (range 2 days-100 years old; IQR 39-63 years old) with the majority of cases (77.8%) aged between 30–69 years. Among reported cases, 51.1% are male, 77.0% are from Hubei and 21.6% are farmers or laborers by occupation.

Zoonotic origins

COVID-19 is a zoonotic virus. From phylogenetics analyses undertaken with available full genome sequences, bats appear to be the reservoir of COVID-19 virus, but the intermediate host(s) has not yet been identified. However, three important areas of work are already underway in China to inform our understanding of the zoonotic origin of this outbreak. These include early investigations of cases with symptom onset in Wuhan throughout December 2019, environmental sampling from the Huanan Wholesale Seafood Market and other area markets, and the collection of detailed records on the source and type of wildlife species sold at the Huanan market and the destination of those animals after the market was closed.

Routes of transmission

COVID-19 is transmitted via droplets and fomites during close unprotected contact between an infector and infectee. Airborne spread has not been reported for COVID-19 and it is not believed to be a major driver of transmission based on available evidence; however, it can be envisaged if certain aerosol-generating procedures are conducted in health care facilities. Fecal shedding has been demonstrated from some patients, and viable virus has been identified in a limited number of case reports. However, the fecal-oral route does not appear to be a driver of COVID-19 transmission; its role and significance for COVID-19 remains to be determined. Viral shedding is discussed in the Technical Findings (Annex C).

Household transmission

In China, human-to-human transmission of the COVID-19 virus is largely occurring in families. The Joint Mission received detailed information from the investigation of clusters and some household transmission studies, which are ongoing in a number of Provinces. Among 344 clusters involving 1308 cases (out of a total 1836 cases reported) in Guangdong Province and Sichuan Province, most clusters (78%-85%) have occurred in families. Household transmission studies are currently underway, but preliminary studies ongoing in Guangdong estimate the secondary attack rate in households ranges from 3-10%.

Contact Tracing

China has a policy of meticulous case and contact identification for COVID-19. For example, in Wuhan more than 1800 teams of epidemiologists, with a minimum of 5 people/team, are tracing tens of thousands of contacts a day. Contact follow up is painstaking, with a high percentage of identified close contacts completing medical observation. Between 1% and 5% of contacts were subsequently laboratory confirmed cases of COVID-19, depending on location. For example:

- As of 17 February, in Shenzhen City, among 2842 identified close contacts, 2842 (100%) were traced and 2240 (72%) have completed medical observation. Among the close contacts, 88 (2.8%) were found to be infected with COVID-19.

- As of 17 February, in Sichuan Province, among 25493 identified close contacts, 25347 (99%) were traced and 23178 (91%) have completed medical observation. Among the close contacts, 0.9% were found to be infected with COVID-19.
- As of 20 February, in Guangdong Province, among 9939 identified close contacts, 9939 (100%) were traced and 7765 (78%) have completed medical observation. Among the close contacts, 479 (4.8%) were found to be infected with COVID-19.

Testing at fever clinics and from routine ILI/SARI surveillance

The Joint Mission systematically enquired about testing for COVID-19 from routine respiratory disease surveillance systems to explore if COVID-19 is circulating more broadly and undetected in the community in China. These systems could include RT-PCR testing of COVID-19 virus in influenza-like-illness (ILI) and severe acute respiratory infection (SARI) surveillance systems, as well as testing of results among all visitors to fever clinics.

In Wuhan, COVID-19 testing of ILI samples (20 per week) in November and December 2019 and in the first two weeks of January 2020 found no positive results in the 2019 samples, 1 adult positive in the first week of January, and 3 adults positive in the second week of January; all children tested were negative for COVID-19 although a number were positive for influenza. In Guangdong, from 1-14 January, only 1 of more than 15000 ILI/SARI samples tested positive for the COVID-19 virus. In one hospital in Beijing, there were no COVID-19 positive samples among 1910 collected from 28 January 2019 to 13 February 2020. In a hospital in Shenzhen, 0/40 ILI samples were positive for COVID-19.

Within the fever clinics in Guangdong, the percentage of samples that tested positive for the COVID-19 virus has decreased over time from a peak of 0.47% positive on 30 January to 0.02% on 16 February. Overall in Guangdong, 0.14% of approximately 320,000 fever clinic screenings were positive for COVID-19.

Susceptibility

As COVID-19 is a newly identified pathogen, there is no known pre-existing immunity in humans. Based on the epidemiologic characteristics observed so far in China, everyone is assumed to be susceptible, although there may be risk factors increasing susceptibility to infection. This requires further study, as well as to know whether there is neutralising immunity after infection.

The transmission dynamics

Inferring from Figures 2 and 3, and based on our observations at the national and provincial/municipal levels during the Joint Mission, we summarize and interpret the transmission dynamics of COVID-19 thus far. It is important to note that transmission dynamics of any outbreak are inherently contextual. For COVID-19, we observe four major types of transmission dynamics during the epidemic growth phase and in the post-control period, and highlight what is known about transmission in children, as follows:

Transmission in Wuhan

Early cases identified in Wuhan are believed to be have acquired infection from a zoonotic source as many reported visiting or working in the Huanan Wholesale Seafood Market. As of 25 February, an animal source has not yet been identified.

At some point early in the outbreak, some cases generated human-to-human transmission chains that seeded the subsequent community outbreak prior to the implementation of the comprehensive control measures that were rolled out in Wuhan. The dynamics likely approximated mass action and radiated from Wuhan to other parts of Hubei province and China, which explains a relatively high R_0 of 2-2.5.

The *cordon sanitaire* around Wuhan and neighboring municipalities imposed since 23 January 2020 has effectively prevented further exportation of infected individuals to the rest of the country.

Transmission in Hubei, other than Wuhan

In the prefectures immediately adjoining Wuhan (Xiaogan, Huanggang, Jingzhou and Ezhou), transmission is less intense. For other prefectures, due to fewer transport links and human mobility flows with Wuhan, the dynamics are more closely aligned with those observed in the other areas of the country. Within Hubei, the implementation of control measures (including social distancing) has reduced the community force of infection, resulting in the progressively lower incident reported case counts.

Transmission in China outside of Hubei

Given Wuhan's transport hub status and population movement during the Chinese New Year (chunyun), infected individuals quickly spread throughout the country, and were particularly concentrated in cities with the highest volume of traffic with Wuhan. Some of these imported seeds generated limited human-to-human transmission chains at their destination.

Given the Wuhan/Hubei experience, a comprehensive set of interventions, including aggressive case and contact identification, isolation and management and extreme social distancing, have been implemented to interrupt the chains of transmission nationwide. To date, most of the recorded cases were imported from or had direct links to Wuhan/Hubei. Community transmission has been very limited. Most locally generated cases have been clustered, the majority of which have occurred in households, as summarized above.

Of note, the highly clustered nature of local transmission may explain a relatively high R_0 (2-2.5) in the absence of interventions and low confirmed case counts with intense quarantine and social distancing measures.

Special settings

We note that instances of transmission have occurred within health care settings prisons and other closed settings. At the present time, it is not clear what role these settings and groups play in transmission. However, they do not appear to be major drivers of the overall epidemic dynamics. Specifically, we note:

(a) **Transmission in health care settings and among health care workers (HCW)** – The Joint Mission discussed nosocomial infection in all locations visited during the Mission. As of 20 February 2020, there were 2,055 COVID-19 laboratory-confirmed cases reported among HCW from 476 hospitals across China. The majority of HCW cases (88%) were reported from Hubei.

Remarkably, more than 40,000 HCW have been deployed from other areas of China to support the response in Wuhan. Notwithstanding discrete and limited instances of nosocomial outbreaks (e.g. a nosocomial outbreak involving 15 HCW in Wuhan), transmission within health care settings and amongst health care workers does not appear to be a major transmission feature of COVID-19 in China. The Joint Mission learned that, among the HCW infections, most were identified early in the outbreak in Wuhan when supplies and experience with the new disease was lower. Additionally, investigations among HCW suggest that many may have been infected within the household rather than in a health care setting. Outside of Hubei, health care worker infections have been less frequent (i.e. 246 of the total 2055 HCW cases). When exposure was investigated in these limited cases, the exposure for most was reported to have been traced back to a confirmed case in a household.

The Joint Team noted that attention to the prevention of infection in health care workers is of paramount importance in China. Surveillance among health care workers identified factors early in the outbreak that placed HCW at higher risk of infection, and this information has been used to modify policies to improve protection of HCW.

(b) **Transmission in closed settings** – There have been reports of COVID-19 transmission in prisons (Hubei, Shandong, and Zhejiang, China), hospitals (as above) and in a long-term living facility. The close proximity and contact among people in these settings and the potential for environmental contamination are important factors, which could amplify transmission. Transmission in these settings warrants further study.

Children

Data on individuals aged 18 years old and under suggest that there is a relatively low attack rate in this age group (2.4% of all reported cases). Within Wuhan, among testing of ILI samples, no children were positive in November and December of 2019 and in the first two weeks of January 2020. From available data, and in the absence of results from serologic studies, it is not possible to determine the extent of infection among children, what role children play in transmission, whether children are less susceptible or if they present differently clinically (i.e. generally milder presentations). The Joint Mission learned that infected children have largely been identified through contact tracing in households of adults. Of note, people interviewed by the Joint Mission Team could not recall episodes in which transmission occurred from a child to an adult.

The signs, symptoms, disease progression and severity

Symptoms of COVID-19 are non-specific and the disease presentation can range from no symptoms (asymptomatic) to severe pneumonia and death. As of 20 February 2020 and

based on 55924 laboratory confirmed cases, typical **signs and symptoms** include: fever (87.9%), dry cough (67.7%), fatigue (38.1%), sputum production (33.4%), shortness of breath (18.6%), sore throat (13.9%), headache (13.6%), myalgia or arthralgia (14.8%), chills (11.4%), nausea or vomiting (5.0%), nasal congestion (4.8%), diarrhea (3.7%), and hemoptysis (0.9%), and conjunctival congestion (0.8%).

People with COVID-19 generally develop signs and symptoms, including mild respiratory symptoms and fever, on an average of 5-6 days after infection (mean incubation period 5-6 days, range 1-14 days).

Most people infected with COVID-19 virus have mild disease and recover. Approximately 80% of laboratory confirmed patients have had **mild to moderate disease**, which includes non-pneumonia and pneumonia cases, 13.8% have **severe disease** (dyspnea, respiratory frequency ≥30/minute, blood oxygen saturation ≤93%, PaO2/FiO2 ratio <300, and/or lung infiltrates >50% of the lung field within 24-48 hours) and 6.1% are **critical** (respiratory failure, septic shock, and/or multiple organ dysfunction/failure). **Asymptomatic infection** has been reported, but the majority of the relatively rare cases who are asymptomatic on the date of identification/report went on to develop disease. The proportion of truly asymptomatic infections is unclear but appears to be relatively rare and does not appear to be a major driver of transmission.

Individuals at **highest risk** for severe disease and death include people aged over 60 years and those with underlying conditions such as hypertension, diabetes, cardiovascular disease, chronic respiratory disease and cancer. Disease in **children** appears to be relatively rare and mild with approximately 2.4% of the total reported cases reported amongst individuals aged under 19 years. A very small proportion of those aged under 19 years have developed severe (2.5%) or critical disease (0.2%).

As of 20 February, 2114 of the 55,924 laboratory confirmed cases have died (**crude fatality ratio** [CFR[2]] 3.8%) (note: at least some of whom were identified using a case definition that included pulmonary disease). The overall CFR varies by location and intensity of transmission (i.e. 5.8% in Wuhan vs. 0.7% in other areas in China). In China, the overall CFR was higher in the early stages of the outbreak (17.3% for cases with symptom onset from 1-10 January) and has reduced over time to 0.7% for patients with symptom onset after 1 February (Figure 4). The Joint Mission noted that the standard of care has evolved over the course of the outbreak.

Mortality increases with age, with the highest mortality among people over 80 years of age (CFR 21.9%). The CFR is higher among males compared to females (4.7% vs. 2.8%). By occupation, patients who reported being retirees had the highest CFR at 8.9%. While patients who reported no comorbid conditions had a CFR of 1.4%, patients with comorbid conditions had much higher rates: 13.2% for those with cardiovascular disease, 9.2% for diabetes, 8.4% for hypertension, 8.0% for chronic respiratory disease, and 7.6% for cancer.

[2] The Joint Mission acknowledges the known challenges and biases of reporting crude CFR early in an epidemic.

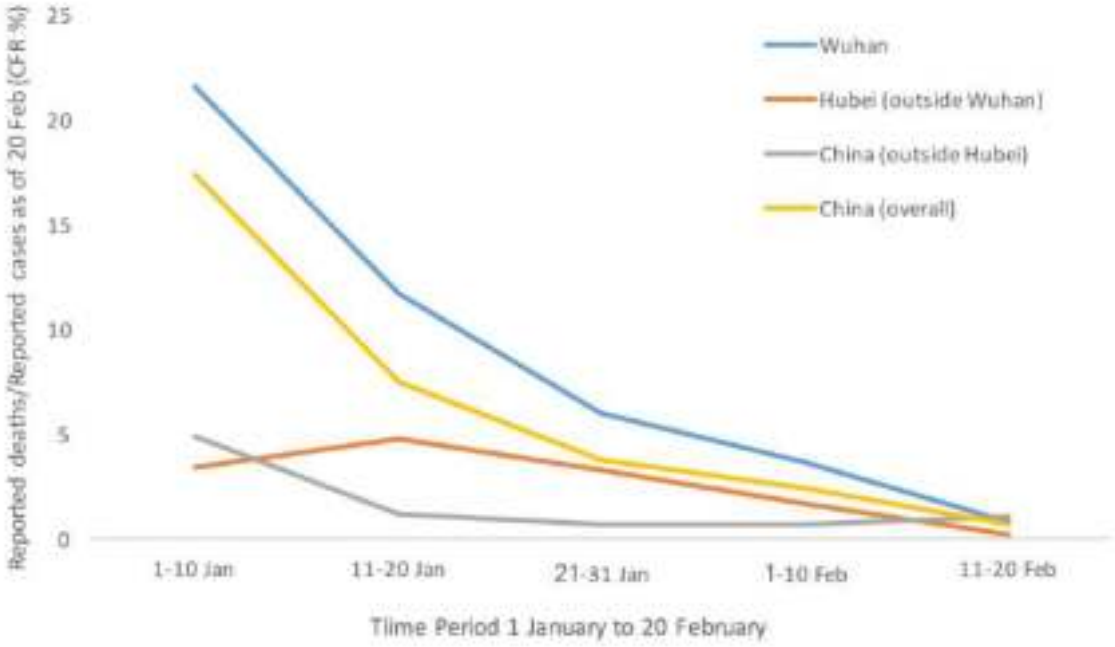

Figure 4 Case fatality ratio (reported deaths among total cases) for COVID-19 in China over time and by location, as of 20 February 2020

Data on the **progression of disease** is available from a limited number of reported hospitalized cases (Figure 5). Based on available information, the median time from symptom onset to laboratory confirmation nationally decreased from 12 days (range 8-18 days) in early January to 3 days (1-7) by early February 2020, and in Wuhan from 15 days (10-21) to 5 days (3-9), respectively. This has allowed for earlier case and contact identification, isolation and treatment.

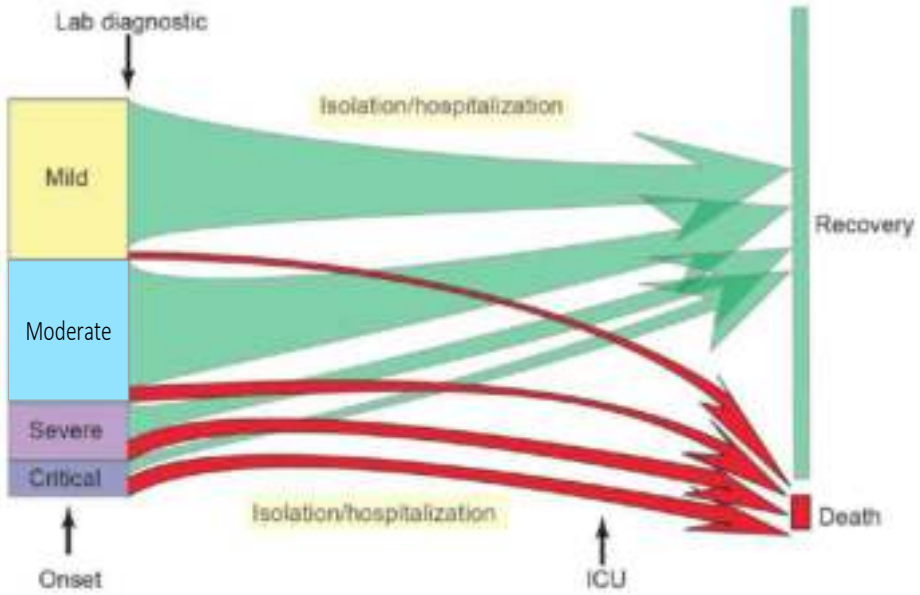

Figure 5. Pattern of disease progression for COVID-19 in China

Note: the relative size of the boxes for disease severity and outcome reflect the proportion of cases reported as of 20 February 2020. The size of the arrows indicates the proportion of cases who recovered or died. Disease definitions are described above. Moderate cases have a mild form of pneumonia.

Using available preliminary data, the median time from onset to clinical recovery for mild cases is approximately 2 weeks and is 3-6 weeks for patients with severe or critical disease. Preliminary data suggests that the time period from onset to the development of severe disease, including hypoxia, is 1 week. Among patients who have died, the time from symptom onset to outcome ranges from 2-8 weeks.

An increasing number of patients have **recovered**; as of 20 February, 18264 (24%) reported cases have recovered. Encouragingly, a report on 20 February from the Guangdong CDC suggests that of 125 severe cases identified in Guangdong, 33 (26.4%) have recovered and been released from hospital, and 58 (46.4%) had improved and were reclassified as having mild/moderate disease (i.e. + milder pneumonia). Among severe cases reported to date, 13.4% have died. Early identification of cases and contacts allows for earlier treatment.

The China response

Upon the detection of a cluster of pneumonia cases of unknown etiology in Wuhan, the CPC Central Committee and the State Council launched the national emergency response. A **Central Leadership Group for Epidemic Response** and the **Joint Prevention and Control Mechanism** of the State Council were established. General Secretary Xi Jinping personally directed and deployed the prevention and control work and requested that the prevention and control of the COVID-19 outbreak be the top priority of government at all levels. Prime Minister Li Keqiang headed the Central Leading Group for Epidemic Response and went to Wuhan to inspect and coordinate the prevention and control work of relevant departments and provinces (autonomous regions and municipalities) across the country. Vice Premier Sun Chunlan, who has been working on the frontlines in Wuhan, has led and coordinated the frontline prevention and control of the outbreak.

The prevention and control measures have been implemented rapidly, from the early stages in Wuhan and other key areas of Hubei, to the current overall national epidemic. It has been undertaken in **three main phases**, with two important events defining those phases. First, COVID-19 was included in the statutory report of Class B infectious diseases and border health quarantine infectious diseases on 20 January 2020, which marked the transition from the initial partial control approach to the comprehensive adoption of various control measures in accordance with the law. The second event was the State Council's issuing, on 8 February 2020, of The Notice on Orderly Resuming Production and Resuming Production in Enterprises, which indicated that China's national epidemic control work had entered a stage of overall epidemic prevention and control together with the restoration of normal social and economic operations.

The first stage

During the early stage of the outbreak, the main strategy focused on preventing the exportation of cases from Wuhan and other priority areas of Hubei Province, and preventing the importation of cases by other provinces; the overall aim was to control the source of infection, block transmission and prevent further spread. The response mechanism was initiated with multi-sectoral involvement in joint prevention and control measures. Wet markets were closed, and efforts were made to identify the zoonotic source. Information on the epidemic was notified to WHO on 3 January, and whole genome sequences of the COVID-19 virus were shared with WHO on 10 January. Protocols for COVID-19 diagnosis and

treatment, surveillance, epidemiological investigation, management of close contacts, and laboratory testing were formulated, and relevant surveillance activities and epidemiological investigations conducted. Diagnostic testing kits were developed, and wildlife and live poultry markets were placed under strict supervision and control measures.

The second stage

During the second stage of the outbreak, the main strategy was to reduce the intensity of the epidemic and to slow down the increase in cases. In Wuhan and other priority areas of Hubei Province, the focus was on actively treating patients, reducing deaths, and preventing exportations. In other provinces, the focus was on preventing importations, curbing the spread of the disease and implementing joint prevention and control measures. Nationally, wildlife markets were closed and wildlife captive-breeding facilities were cordoned off. On 20 January, COVID-19 was included in the notifiable report of Class B infectious diseases and border health quarantine infectious diseases, with temperature checks, health care declarations, and quarantine against COVID-19 instituted at transportation depots in accordance with the law. On 23 January, Wuhan implemented strict traffic restrictions. The protocols for diagnosis, treatment and epidemic prevention and control were improved; case isolation and treatment were strengthened.

Measures were taken to ensure that all cases were treated, and close contacts were isolated and put under medical observation. Other measures implemented included the extension of the Spring Festival holiday, traffic controls, and the control of transportation capacity to reduce the movement of people; mass gathering activities were also cancelled. Information about the epidemic and prevention and control measures was regularly released. Public risk communications and health education were strengthened; allocation of medical supplies was coordinated, new hospitals were built, reserve beds were used and relevant premises were repurposed to ensure that all cases could be treated; efforts were made to maintain a stable supply of commodities and their prices to ensure the smooth operation of society.

The third stage

The third stage of the outbreak focused on reducing clusters of cases, thoroughly controlling the epidemic, and striking a balance between epidemic prevention and control, sustainable economic and social development, the unified command, standardized guidance, and scientific evidence-based policy implementation. For Wuhan and other priority areas of Hubei Province, the focus was on patient treatment and the interruption of transmission, with an emphasis on concrete steps to fully implement relevant measures for the testing, admitting and treating of all patients. A risk-based prevention and control approach was adopted with differentiated prevention and control measures for different regions of the country and provinces. Relevant measures were strengthened in the areas of epidemiological investigation, case management and epidemic prevention in high-risk public places.

New technologies were applied such as the use of big data and artificial intelligence (AI) to strengthen contact tracing and the management of priority populations. Relevant health insurance policies were promulgated on "health insurance payment, off-site settlement, and financial compensation". All provinces provided support to Wuhan and priority areas in Hubei Province in an effort to quickly curb the spread of the disease and provide timely clinical treatment. Pre-school preparation was improved, and work resumed in phases and

batches. Health and welfare services were provided to returning workers in a targeted and 'one-stop' manner. Normal social operations are being restored in a stepwise fashion; knowledge about disease prevention is being popularized to improve public health literacy and skills; and a comprehensive program of emergency scientific research is being carried out to develop diagnostics, therapeutics and vaccines, delineate the spectrum of the disease, and identify the source of the virus.

Knowledge gaps

Since the start of the COVID-19 outbreak, there have been extensive attempts to better understand the virus and the disease in China. It is remarkable how much knowledge about a new virus has been gained in such a short time. However, as with all new diseases, and only 7 weeks after this outbreak began, key knowledge gaps remain. Annex D summarizes the key unknowns in a number of areas including the source of infection, pathogenesis and virulence of the virus, transmissibility, risk factors for infection and disease progression, surveillance, diagnostics, clinical management of severe and critically ill patients, and the effectiveness of prevention and control measures. The timely filling of these knowledge gaps is imperative to enhance control strategies.

III. Assessment

The Joint Mission drew four major conclusions from its work in China and four major conclusions from its knowledge of the broader global response to COVID-19. Recommendations are offered in five major areas to inform the ongoing response globally and in China.

The China Response & Next Steps

1. **In the face of a previously unknown virus, China has rolled out perhaps the most ambitious, agile and aggressive disease containment effort in history. The strategy that underpinned this containment effort was initially a national approach that promoted universal temperature monitoring, masking, and hand washing. However, as the outbreak evolved, and knowledge was gained, a science and risk-based approach was taken to tailor implementation. Specific containment measures were adjusted to the provincial, county and even community context, the capacity of the setting, and the nature of novel coronavirus transmission there.**

   While the fundamental principles of this strategy have been consistent since its launch, there has been constant refinement of specific aspects to incorporate new knowledge on the novel coronavirus, the COVID-19 disease, and COVID-19 containment, as rapidly as that knowledge has emerged. The remarkable speed with which Chinese scientists and public health experts isolated the causative virus, established diagnostic tools, and determined key transmission parameters, such as the route of spread and incubation period, provided the vital evidence base for China's strategy, gaining invaluable time for the response.

As striking, has been the uncompromising rigor of strategy application that proved to be a hallmark in every setting and context where it was examined. There has also been a relentless focus on improving key performance indicators, for example constantly enhancing the speed of case detection, isolation and early treatment. The implementation of these containment measures has been supported and enabled by the innovative and aggressive use of cutting edge technologies, from shifting to online medical platforms for routine care and schooling, to the use of 5G platforms to support rural response operations.

2. **Achieving China's exceptional coverage with and adherence to these containment measures has only been possible due to the deep commitment of the Chinese people to collective action in the face of this common threat. At a community level this is reflected in the remarkable solidarity of provinces and cities in support of the most vulnerable populations and communities. Despite ongoing outbreaks in their own areas, Governors and Mayors have continued to send thousands of health care workers and tons of vital PPE supplies into Hubei province and Wuhan city.**

   At the individual level, the Chinese people have reacted to this outbreak with courage and conviction. They have accepted and adhered to the starkest of containment measures – whether the suspension of public gatherings, the month-long 'stay at home' advisories or prohibitions on travel. Throughout an intensive 9-days of site visits across China, in frank discussions from the level of local community mobilizers and frontline health care providers to top scientists, Governors and Mayors, the Joint Mission was struck by the sincerity and dedication that each brings to this COVID-19 response.

3. **China's bold approach to contain the rapid spread of this new respiratory pathogen has changed the course of a rapidly escalating and deadly epidemic. A particularly compelling statistic is that on the first day of the advance team's work there were 2478 newly confirmed cases of COVID-19 reported in China. Two weeks later, on the final day of this Mission, China reported 409 newly confirmed cases. This decline in COVID-19 cases across China is real.**

   Several sources of data support this conclusion, including the steep decline in fever clinic visits, the opening up of treatment beds as cured patients are discharged, and the challenges to recruiting new patients for clinical trials. Based on a comparison of crude attack rates across provinces, the Joint Mission estimates that this truly all-of-Government and all-of-society approach that has been taken in China has averted or at least delayed hundreds of thousands of COVID-19 cases in the country. By extension, the reduction that has been achieved in the force of COVID-19 infection in China has also played a significant role in protecting the global community and creating a stronger first line of defense against international spread. Containing this outbreak, however, has come at great cost and sacrifice by China and its people, in both human and material terms.

   While the scale and impact of China's COVID-19 operation has been remarkable, it has also highlighted areas for improvement in public health emergency response capacity.

These include overcoming any obstacles to act immediately on early alerts, to massively scale-up capacity for isolation and care, to optimize the protection of frontline health care workers in all settings, to enhance collaborative action on priority gaps in knowledge and tools, and to more clearly communicate key data and developments internationally.

4. **China is already, and rightfully, working to bolster its economy, reopen its schools and return to a more normal semblance of its society, even as it works to contain the remaining chains of COVID-19 transmission. Appropriately, a science-based, risk-informed and phased approach is being taken, with a clear recognition and readiness of the need to immediately react to any new COVID-19 cases or clusters as key elements of the containment strategy are lifted.**

   Despite the declining case numbers, across China every province, city and community visited is urgently escalating their investments in acute care beds and public health capacity. It is crucial that this continues. Fifty thousand infected COVID-19 patient are still under treatment, across the country. However, the Joint Mission has come to understand the substantial knowledge, experience and capacities that China has rapidly built during this crisis. Consequently, it endorses China's working assumption that in most provinces and municipalities it should soon be possible to manage a resurgence in COVID-19 cases, using even more tailored and sustainable approaches that are anchored in very rapid case detection, instant activation of key containment activities, direct oversight by top leadership, and broad community engagement.

   As China works to resume a more normal level of societal and economic activity, it is essential that the world recognizes and reacts positively to the rapidly changing, and decreasing, risk of COVID-19 in the country. China's rapid return to full connectivity with the world, and to full productivity and economic output, is vital to China and to the world. The world urgently needs access to China's experience in responding to COVID-19, as well as the material goods it brings to the global response. It is even more urgent now, with escalating COVID-19 outbreaks outside of China, to constantly reassess any restrictions on travel and/or trade to China that go beyond the recommendations of the IHR Emergency Committee on COVID-19.

The Global Response & Next Steps

1. **The COVID-19 virus is a new pathogen that is highly contagious, can spread quickly, and must be considered capable of causing enormous health, economic and societal impacts in any setting. It is not SARS and it is not influenza. Building scenarios and strategies only on the basis of well-known pathogens risks failing to exploit all possible measures to slow transmission of the COVID-19 virus, reduce disease and save lives.**

   COVID-19 is not SARS and it is not influenza. It is a new virus with its own characteristics. For example, COVID-19 transmission in children appears to be limited compared with influenza, while the clinical picture differs from SARS. Such differences, while based on limited data, may be playing a role in the apparent efficacy of rigorously

applied non-pharmaceutical, public health measures to interrupt chains of human-to-human transmission in a range of settings in China. The COVID-19 virus is unique among human coronaviruses in its combination of high transmissibility, substantial fatal outcomes in some high-risk groups, and ability to cause huge societal and economic disruption. For planning purposes, it must be assumed that the global population is susceptible to this virus. As the animal origin of the COVID-19 virus is unknown at present, the risk of reintroduction into previously infected areas must be constantly considered.

The novel nature, and our continuously evolving understanding, of this coronavirus demands a tremendous agility in our capacity to rapidly adapt and change our readiness and response planning as has been done continually in China. This is an extraordinary feat for a country of 1.4 billion people.

2. **China's uncompromising and rigorous use of non-pharmaceutical measures to contain transmission of the COVID-19 virus in multiple settings provides vital lessons for the global response. This rather unique and unprecedented public health response in China reversed the escalating cases in both Hubei, where there has been widespread community transmission, and in the importation provinces, where family clusters appear to have driven the outbreak.**

   Although the timing of the outbreak in China has been relatively similar across the country, transmission chains were established in a wide diversity of settings, from mega-cities in the north and south of the country, to remote communities. However, the rapid adaptation and tailoring of China's strategy demonstrated that containment can be adapted and successfully operationalized in a wide range of settings.

   China's experience strongly supports the efficacy and effectiveness of anchoring COVID-19 readiness and rapid response plans in a thorough assessment of local risks and of utilizing a differentiated risk-based containment strategy to manage the outbreak in areas with no cases vs. sporadic cases vs. clusters of cases vs. community-level transmission. Such a strategy is essential for ensuring a sustainable approach while minimizing the socio-economic impact.

3. **Much of the global community is not yet ready, in mindset and materially, to implement the measures that have been employed to contain COVID-19 in China. These are the only measures that are currently proven to interrupt or minimize transmission chains in humans. Fundamental to these measures is extremely proactive surveillance to immediately detect cases, very rapid diagnosis and immediate case isolation, rigorous tracking and quarantine of close contacts, and an exceptionally high degree of population understanding and acceptance of these measures.**

   Achieving the high quality of implementation needed to be successful with such measures requires an unusual and unprecedented speed of decision-making by top leaders, operational thoroughness by public health systems, and engagement of society.

Given the damage that can be caused by uncontrolled, community-level transmission of this virus, such an approach is warranted to save lives and to gain the weeks and months needed for the testing of therapeutics and vaccine development. Furthermore, as the majority of new cases outside of China are currently occurring in high and middle-income countries, a rigorous commitment to slowing transmission in such settings with non-pharmaceutical measures is vital to achieving a second line of defense to protect low income countries that have weaker health systems and coping capacities.

The time that can be gained through the full application of these measures – even if just days or weeks – can be invaluable in ultimately reducing COVID-19 illness and deaths. This is apparent in the huge increase in knowledge, approaches and even tools that has taken place in just the 7 weeks since this virus was discovered through the rapid scientific work that has been done in China.

4. **The time gained by rigorously applying COVID-19 containment measures must be used more effectively to urgently enhance global readiness and rapidly develop the specific tools that are needed to ultimately stop this virus.**

COVID-19 is spreading with astonishing speed; COVID-19 outbreaks in any setting have very serious consequences; and there is now strong evidence that non-pharmaceutical interventions can reduce and even interrupt transmission. Concerningly, global and national preparedness planning is often ambivalent about such interventions. However, to reduce COVID-19 illness and death, near-term readiness planning must embrace the large-scale implementation of high-quality, non-pharmaceutical public health measures. These measures must fully incorporate immediate case detection and isolation, rigorous close contact tracing and monitoring/quarantine, and direct population/community engagement.

A huge array of COVID-19 studies, scientific research projects and product R&D efforts are ongoing in China and globally. This is essential and to be encouraged and supported. However, such a large number of projects and products needs to be prioritized. Without prioritizing, this risks compromising the concentration of attention and resources and collaboration required to cut timelines by precious weeks and months. While progress has been made, the urgency of the COVID-19 situation supports an even more ruthless prioritization of research in the areas of diagnostics, therapeutics and vaccines.

Similarly, there is a long list of proposed studies on the origins of COVID-19, the natural history of the disease, and the virus's transmission dynamics. However, the urgency of responding to cases and saving lives makes it difficult for policy makers to consider and act on such comprehensive lists. This can be addressed by balancing studies with the immediate public health and clinical needs of the response. Studies can be prioritized in terms of the largest knowledge gaps that can be most rapidly addressed to have greatest immediate impact on response operations and patient management. This suggests prioritizing studies to identify risk factors for transmission in households, institutions and the community; convenience sampling for this virus in the population using existing surveillance systems; age-stratified sero-epidemiologic surveys; the analysis of clinical case series; and cluster investigations.

IV. Major Recommendations

For China

1. Maintain an appropriate level of emergency management protocols, depending on the assessed risk in each area and recognizing the real risk of new cases and clusters of COVID-19 as economic activity resumes, movement restrictions are lifted, and schools reopen;

2. Carefully monitor the phased lifting of the current restrictions on movement and public gatherings, beginning with the return of workers and migrant labor, followed by the eventual reopening of schools and lifting other measures;

3. Further strengthen the readiness of emergency management mechanisms, public health institutions (e.g. CDCs), medical facilities, and community engagement mechanisms to ensure sustained capacity to immediately launch containment activities in response to any resurgence in cases;

4. Prioritize research that rapidly informs response and risk management decisions, particularly household and health care facility studies, age-stratified sero-epidemiologic surveys and rigorous investigation of the animal-human interface; establish a centralized research program to fast-track the most promising rapid diagnostics and serologic assays, the testing of potential antivirals and vaccine candidates, and Chinese engagement in selected multi-country trials; and

5. As the country with the greatest knowledge on COVID-19, further enhance the systematic and real-time sharing of epidemiologic data, clinical results and experience to inform the global response.

For countries with imported cases and/or outbreaks of COVID-19

1. Immediately activate the highest level of national Response Management protocols to ensure the all-of-government and all-of-society approach needed to contain COVID-19 with non-pharmaceutical public health measures;

2. Prioritize active, exhaustive case finding and immediate testing and isolation, painstaking contact tracing and rigorous quarantine of close contacts;

3. Fully educate the general public on the seriousness of COVID-19 and their role in preventing its spread;

4. Immediately expand surveillance to detect COVID-19 transmission chains, by testing all patients with atypical pneumonias, conducting screening in some patients with upper respiratory illnesses and/or recent COVID-19 exposure, and adding testing for the COVID-19 virus to existing surveillance systems (e.g. systems for influenza-like-illness and SARI); and

5. Conduct multi-sector scenario planning and simulations for the deployment of even more stringent measures to interrupt transmission chains as needed (e.g. the suspension of large-scale gatherings and the closure of schools and workplaces).

For uninfected countries

1. Prepare to immediately activate the highest level of emergency response mechanisms to trigger the all-of-government and all-of society approach that is essential for early containment of a COVID-19 outbreak;

2. Rapidly test national preparedness plans in light of new knowledge on the effectiveness of non-pharmaceutical measures against COVID-19; incorporate rapid detection, largescale case isolation and respiratory support capacities, and rigorous contact tracing and management in national COVID-19 readiness and response plans and capacities;

3. Immediately enhance surveillance for COVID-19 as rapid detection is crucial to containing spread; consider testing all patients with atypical pneumonia for the COVID-19 virus, and adding testing for the virus to existing influenza surveillance systems;

4. Begin now to enforce rigorous application of infection prevention and control measures in all healthcare facilities, especially in emergency departments and outpatient clinics, as this is where COVID-19 will enter the health system; and

5. Rapidly assess the general population's understanding of COVID-19, adjust national health promotion materials and activities accordingly, and engage clinical champions to communicate with the media.

For the public

1. Recognize that COVID-19 is a new and concerning disease, but that outbreaks can managed with the right response and that the vast majority of infected people will recover;

2. Begin now to adopt and rigorously practice the most important preventive measures for COVID-19 by frequent hand washing and always covering your mouth and nose when sneezing or coughing;

3. Continually update yourself on COVID-19 and its signs and symptoms (i.e. fever and dry cough), because the strategies and response activities will constantly improve as new information on this disease is accumulating every day; and

4. Be prepared to actively support a response to COVID-19 in a variety of ways, including the adoption of more stringent 'social distancing' practices and helping the high-risk elderly population.

For the international community

1. Recognize that true solidarity and collaboration is essential between nations to tackle the common threat that COVID-19 represents and operationalize this principle;

2. Rapidly share information as required under the International Health Regulations (IHR) including detailed information about imported cases to facilitate contact tracing and inform containment measures that span countries;

3. Recognize the rapidly changing risk profile of COVID-19 affected countries and continually monitor outbreak trends and control capacities to reassess any 'additional health measures' that significantly interfere with international travel and trade.

_____

Annexes

A. WHO-China Joint Mission Members

Bruce AYLWARD	Team Lead WHO-China Joint Mission on COVID-19, Senior Advisor to the Director-General, World Health Organization, Geneva, Switzerland
Wannian LIANG	Team Lead WHO-China Joint Mission on COVID-19, Head of Expert Panel, National Health Commission
Xiaoping DONG	Director and Researcher, Center for Global Public Health, Chinese Center for Disease Control and Prevention
Tim ECKMANNS	Head of Unit, Healthcare-associated Infections, Surveillance of Antibiotic Resistance and Consumption, Robert Koch Institute, Berlin, Germany
Dale FISHER	Professor of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore
Chikwe IHEKWEAZU	Director General, Nigeria Centre for Disease Control, Nigeria Centre for Disease Control, Abuja, Nigeria
Clifford LANE	Clinical Director, National Institute of Allergy and Infectious Diseases, US National Institutes of Health, Bethesda, United States
Jong-Koo LEE	Professor of Family Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea
Gabriel LEUNG	Dean of Medicine, Helen and Francis Zimmern Professor in Population Health, The University of Hong Kong, Hong Kong SAR, China
Jiangtao LIN	Director and Professor, Department of Pulmonary and Critical Care Medicine, China-Japan Friendship Hospital, National Clinical Research Center for Respiratory Diseases, Beijing
Haiying LIU	Deputy Director and Researcher, Institute of Pathogen Biology, Chinese Academy of Medical Sciences, Beijing China
Natalia PSHENICHNAYA	Head of International Department and Consultant, Center of Infectious Diseases, National Medical Research Center of Phthisiopulmonology and Infectious Diseases, Moscow, Russia
Aleksandr SEMENOV	Deputy Director, Saint Petersburg Pasteur Institute, Saint Petersburg, Russia
Hitoshi TAKAHASHI	Senior Research Scientist, Influenza Virus Research Center, National Institute of Infectious Diseases, Tokyo, Japan
Maria VAN KERKHOVE	Head of Unit, Emerging Diseases & Zoonoses, Global Infectious Hazard Preparedness, World Health Organization, Geneva, Switzerland
Bin WANG	Deputy Team Leader, Deputy Director General, Disease Prevention and Control Bureau, National Health Commission
Guangfa WANG	Director, Department of Respiratory and Critical Care Medicine, Peking University First Hospital
Fan WU	Vice Dean, Shanghai Medical College, Fudan University
Zhongze WU	Director, Compliance and Enforcement Division, Department of Wildlife Conservation, National Forestry and Grassland Administration
Zunyou WU	Chief Epidemiologist, Chinese Center for Disease Control and Prevention
Jun XING	Head of Unit, Country Capacity for International Health Regulations, Health Security Preparedness, World Health Organization, Geneva, Switzerland
Kwok-Yung YUEN	Chair Professor and Co-Director of State Key Laboratory of Emerging Infectious Diseases, Department of Microbiology, The University of Hong Kong
Weigong ZHOU	Medical Officer, Influenza Division, National Center for Immunization and Respiratory Diseases, US Centers for Disease Control and Prevention, Atlanta, United States
Yong ZHANG	Assistant Director and Researcher, National Institute for Viral Disease Control and prevention, Chinese Center for Disease Control and Prevention.
Lei ZHOU	Chief and Researcher, Branch for Emerging Infectious Disease, Public Health Emergency Center, Chinese Center for Disease Control and Prevention

B. Summary Agenda of the Mission

Dates	Location	Activities
10-15 February 2020 (Advance Team)	Beijing	Advance Team and WHO Country team meetings with national counterparts and institutions
16 February 2020	Beijing	Meeting with the full international team for briefing at the WHO Country office
	Beijing	Workshop at the National Health Commission (NHC) with relevant departments of the Joint Prevention and Control Mechanism of the State Council
17 February 2020	Beijing	Site visit to Beijing Ditan Hospital
	Beijing	Site visit to Anhuali community and health service station, Anzhen street, Chaoyang District, Beijing
	Beijing	Workshop with Chinese Center for Disease Control and Prevention
18 February 2020 (Guangdong Team)	Shenzhen, Guangdong	Shenzhen customs at the airport
	Shenzhen, Guangdong	Shenzhen No.3 People's Hospital
	Shenzhen, Guangdong	Shenzhen Center for Disease Control and Prevention
	Shenzhen, Guangdong	Meeting at Tencent
19 February 2020 (Guangdong Team)	Shenzhen, Guangdong	Qiaoxiang community
	Shenzhen to Guangzhou	Visit to Futian High-speed Train Station, and travel to Guangzhou by train
	Guangzhou	Guangzhou Panyu Sanatorium
	Guangzhou	Guangdong Laboratory of Regenerative Medicine and Health
	Guangzhou	Guangzhou Tiyudongzhihui wet market
	Guangzhou	First Workshop with The People's government of Guangdong Province
20 February 2020 (Guangdong Team)	Guangzhou	Guangdong Provincial Center for Disease Control and Prevention
	Guangzhou	Renmin road campus of Guangzhou Women and Children Medical Center
	Guangzhou	The second Workshop with The People's government of Guangdong Province
18 February 2020 (Sichuan Team)	Beijing to Chengdu	
	Sichuan	Site visit to Chengdu Shuangliu International Airport
		Meeting with the Governor of Sichuan Provincial People's Government
		Site visit to Yong'an Township Central hospital with fever clinic
		Site visit to home community of Yong'an township
19 February 2020 (Sichuan Team)		Symposium with provincial and municipal authorities
		Sichuan Center for Disease Control and Prevention
		Site visit to West China Hospital- Designated COVID-19 hospital
20 February 2020 (Sichuan Team)		Site visit to Chengdu Women and Children's hospital
		Site visit to Pharmaceutical Logistics center
		Site visit to East Chengdu railway station

		Site visit to Chengdu Public Health Clinical Centre- Designated COVID 19 hospital
Sichuan and Guangdong teams reconvene in Guangzhou		
21-24 February 2020		Analyze major findings; Meetings of the WHO-China Joint mission to finalize the report
Feb 22 (Wuhan Team)	Guangzhou to Wuhan	Select team members only
23 February (Wuhan Team)		Site visit to Guanggu Campus of Wuhan Tongji Hospital
		Site visit to Mobile Cabin Hospital in Wuhan Sports Center
		Workshop with relevant departments of the Joint Prevention and Control Mechanism of Hubei Province
		Feedback Meeting with Minister Ma, NHC at the Wuhan Conference Center
24 February 2020	Guangzhou to Beijing	Finalize report, WHO-Joint Press conference in Beijing

C. Detailed Technical Findings

Response management, case and contact management, risk communication and community engagement

The response structures in China were rapidly put in place according to existing emergency plans and aligned from the top to the bottom. This was replicated at the four levels of government (national provincial, prefecture and county/district).

Organizational structure and response mechanism

Response activation at the national level: COVID-19 prevention and control mechanisms were initiated immediately after the outbreak was declared and nine working groups were set up to coordinate the response: a) Coordination b) Epidemic prevention and control c) Medical treatment d) Research e) Public communication f) Foreign affairs g) Medical material support h) Life maintenance supplies and i) Social stability. Each working group has a ministerial level leader. Emergency response laws and regulations for the emergency response to public health emergencies, prevention and control of infectious diseases have been developed or updated to guide the response.

Response activation in provinces: Each province set up a similar structure to manage the outbreak. The response is organized at the levels of national, provincial, prefecture, county/district and the community. By 29 January, all provinces across China had launched the highest level of response for major public health emergencies.

Response Strategy

A clear strategy was developed, and goals were well articulated and communicated across the entire response architecture. This strategy was rapidly adapted and adjusted to the outbreak, both in terms of the epidemiological situation over time and in different parts of the country.

The epidemiological situation has been used to define location into four areas:

- In areas without cases, the strategy in these areas is to "strictly prevent introduction". This includes quarantine arrangements in transportation hubs, monitoring for temperature changes, strengthening of triage arrangements, use of fever clinics, and ensuring normal economic and social operations.
- In areas with sporadic cases, the strategy is focused on "reducing importation, stopping transmission and providing appropriate treatment".
- In areas with community clusters, the strategy is focussed on "stopping transmission, preventing exportation, and strengthening treatment".
- In areas with community transmission, the strictest prevention and control strategies are being implemented, the entry and exit of people from these areas has been stopped and public health and medical treatment measures are comprehensively strengthened.

Main control measures implemented in China

The main control measures implemented in China are as follows and are illustrated in Figures 6A-6D, representing the national level response and examples of the response at the Provincial and municipal levels:

Monitoring and reporting: COVID-19 was included in the statutory reporting of infectious diseases on 20 January and plans were formulated to strengthen diagnosis, monitoring, and reporting.

Strengthening ports of entry and quarantine: The Customs Department launched the emergency plan for public health emergencies at ports across the country and restarted the health declaration card system for entry and exit into cities as well as strict monitoring of the temperature of entry and exit passengers.

Treatment: For severe or critical patients, the principle of "Four Concentrations" was implemented: i.e. concentrating patients, medical experts, resources and treatment into special centres. All cities and districts transformed relevant hospitals, increased the number of designated hospitals, dispatched medical staff, and set up expert groups for consultation, so as to minimise mortality of severe patients. Medical resources from all over China have been mobilized to support the medical treatment of patients in Wuhan.

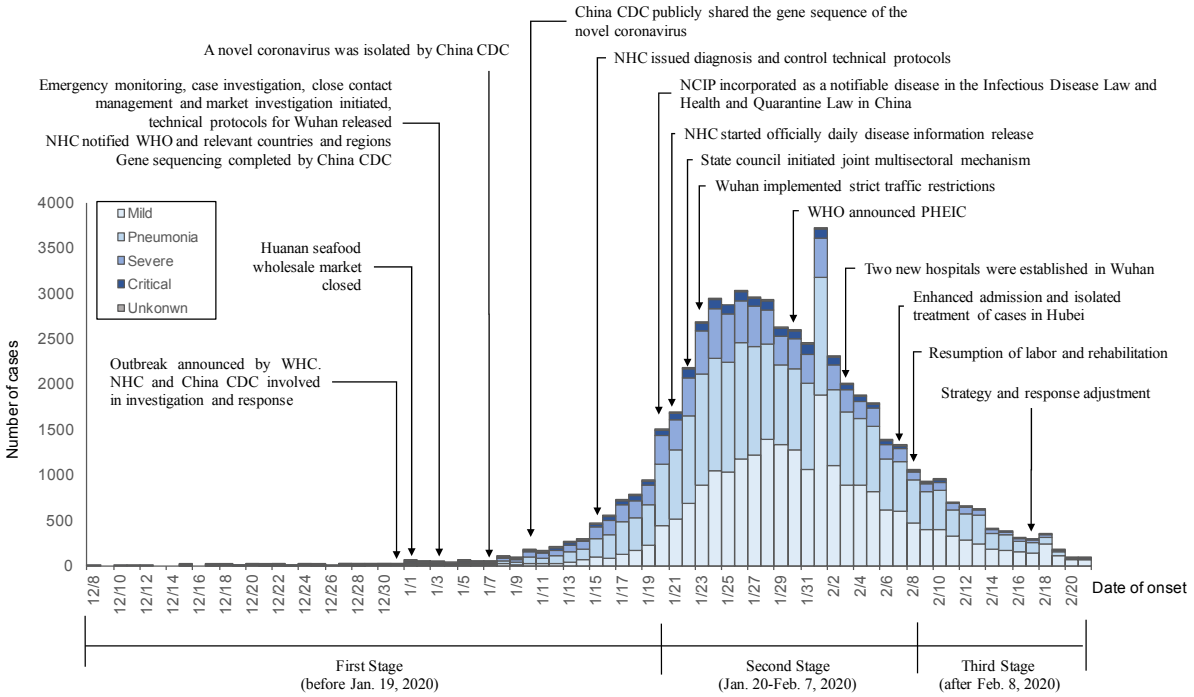
Epidemiological investigation and close contact management: Strong epidemiological investigations are being carried out for cases, clusters, and contacts to identify the source of infection and implement targeted control measures, such as contact tracing.

Social distancing: At the national level, the State Council extended the Spring Festival holiday in 2020, all parts of the country actively cancelled or suspended activities like sport events, cinema, theatre, and schools and colleges in all parts of the country postponed re-opening after the holiday. Enterprises and institutions have staggered their return to work. Transportation Departments setup thousands of health and quarantine stations in national service areas, and in entrances and exits for passengers at stations. Hubei Province adopted the most stringent traffic control measures, such as suspension of urban public transport, including subway, ferry and long-distance passenger transport. Every citizen has to wear a mask in public. Home support mechanisms were established. As a consequence of all of these measures, public life is very reduced.

Funding and material support: Payment of health insurance was taken over by the state, as well as the work to improve accessibility and affordability of medical materials, provide personal protection materials, and ensure basic living materials for affected people.

Emergency material support: The government restored production and expanded production capacity, organized key enterprises that have already started to exceed current production capacity, supported local enterprises to expand imports, and used cross-border e-commerce platforms and enterprises to help import medical materials and improve the ability to guarantee supplies.

A



China CDC publicly shared the gene sequence of the novel coronavirus
A novel coronavirus was isolated by China CDC
NHC issued diagnosis and control technical protocols
Emergency monitoring, case investigation, close contact management and market investigation initiated, technical protocols for Wuhan released
NHC notified WHO and relevant countries and regions
Gene sequencing completed by China CDC
NCIP incorporated as a notifiable disease in the Infectious Disease Law and Health and Quarantine Law in China
NHC started officially daily disease information release
State council initiated joint multisectoral mechanism
Wuhan implemented strict traffic restrictions
WHO announced PHEIC
Mild
Pneumonia
Severe
Critical
Unkonwn
Huanan seafood wholesale market closed
Two new hospitals were established in Wuhan
Enhanced admission and isolated treatment of cases in Hubei
Resumption of labor and rehabilitation
Outbreak announced by WHC. NHC and China CDC involved in investigation and response
Strategy and response adjustment
Number of cases
Date of onset
First Stage (before Jan. 19, 2020)
Second Stage (Jan. 20-Feb. 7, 2020)
Third Stage (after Feb. 8, 2020)

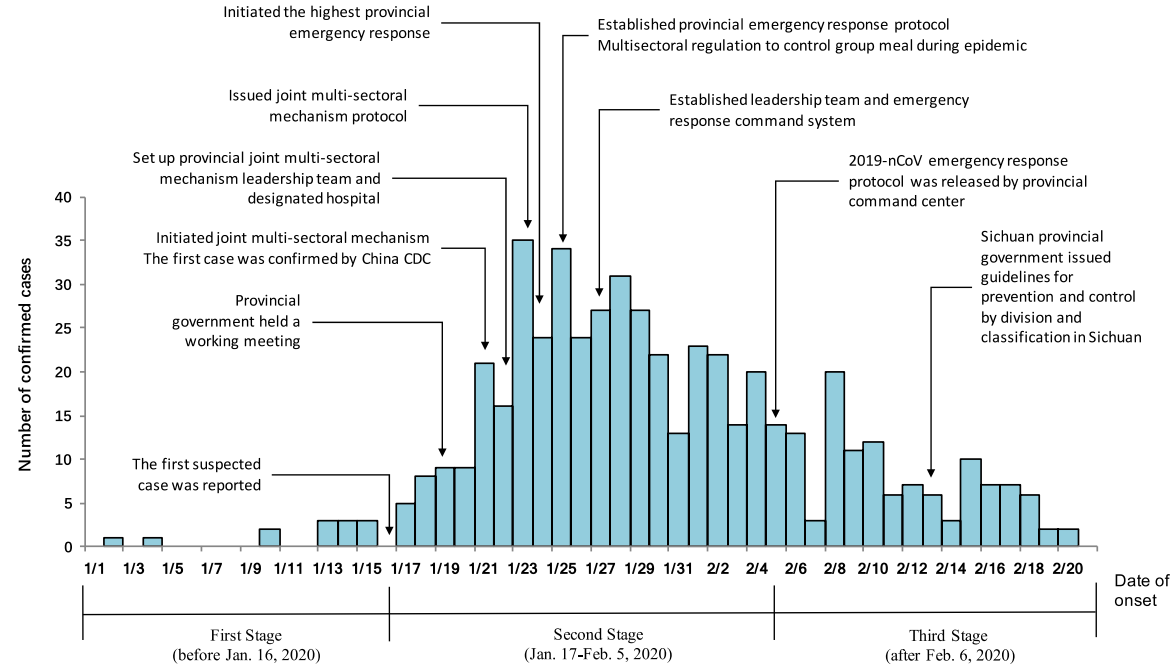

Figure 6. COVID-19 epidemic curves and major intervention measures in China as implemented at a) the national level b) in Guangdong province, c) in Shenzhen municipality and d) in Sichuan province

Risk communications (information release, public and media communications)

International and interregional cooperation and information sharing: From 3 January 2020, information on COVID-19 cases has been reported to WHO daily. Full genome sequences of the new virus were shared with WHO and the international community immediately after the pathogen was identified on 7 January. On 10 January, an expert group involving Hong Kong, Macao and Taiwanese technical experts and a World Health Organization team was invited to visit Wuhan. A set of nucleic acid primers and probes for PCR detection for COVID-19 was released on 21 January.

Daily updates: The National Health Commission announces the epidemic situation every day and holds daily press conferences to respond to emerging issues. The government also frequently invites experts to share scientific knowledge on COVID-19 and to address public concerns.

Psychological care: This is provided to patients and the public. Governments at all levels, NGOs and all sectors of society developed guidelines for emergency psychological crisis intervention and guidelines for public psychological self-support and counselling. A hotline for mental health services has been established for the public.

IT platform: China has capitalized on the use of technology, big data and AI for COVID-19 preparedness, readiness and response. Authoritative and reliable information, medical guidance, access to online services, provision of educational tools and remote work tools have been developed in and used across China. These services have increased accessibility to health services, reduced misinformation and minimized the impact of fake news.

Social mobilization and community engagement

Civil society organizations (community centers and public health centers) have been mobilized to support prevention and response activities. The community has largely accepted the prevention and control measures and is fully participating in the management of self-isolation and enhancement of public compliance. Community volunteers are organized to support self-isolation and help isolated residents at home to solve practical life difficulties. Measures were taken to limit the movement of the population through home-based support. Up to now, outside of Hubei, 30 provinces have registered and managed more than 5 million people coming from Wuhan.

Clinical case management and infection prevention and control

The main **signs and symptoms** of COVID-19 include fever, dry cough, fatigue, sputum production, shortness of breath, myalgia or arthralgia, sore throat, and headache. Nausea or vomiting has been reported in a small percentage of patients (5%). On 14 February, China CDC described the clinical features, outcomes, laboratory and radiologic findings of 44 672 laboratory-confirmed cases. Only 965 (2.2%) were under 20 years of age and there is just one recorded death (0.1%) in this age group. Most patients (77.8%) were aged 30 to 69 years. Patients aged over 80 years had a CFR of 14.8%. The CFR was highest in those with

comorbidities including cardiovascular, diabetes, chronic respiratory disease, hypertension and cancer.

As opposed to Influenza A(H1N1)pdm09, **pregnant women** do not appear to be at higher risk of severe disease. In an investigation of 147 pregnant women (64 confirmed, 82 suspected and 1 asymptomatic), 8% had severe disease and 1% were critical.

Severe cases are defined as tachypnoea (≧30 breaths/ min) or oxygen saturation ≤93% at rest, or PaO2/FIO2 <300 mmHg. **Critical cases** are defined as respiratory failure requiring mechanical ventilation, shock or other organ failure that requires intensive care. About a quarter of severe and critical cases require mechanical ventilation while the remaining 75% require only oxygen supplementation.

China has a principle of **early identification**, early isolation, early diagnosis and early treatment. Early identification of suspect cases is critical to containment efforts and occurs via a process of temperature screening and questioning at entrances to many institutions, communities, travel venues (airports, train stations) and hospitals. Many hospitals have fever clinics that were established and maintained since the SARS outbreak. In China, laboratory tests were originally requested according to the case definitions, which included an epidemiological link to Hubei or other confirmed cases. However, more recently, a more **liberal clinical testing regimen** allows clinicians to test with a low index of suspicion.

Suspect cases are isolated in normal pressure single rooms, wear a surgical mask (for source control). Staff in China wear a cap, eye protection, n95 masks, gown and gloves (single use only). In Wuhan it is necessary for most suspects to be cohorted in a normal pressure isolation ward. Staff wear PPE continuously, changing it only when they leave the ward.

PCR test results are returned the same day. If positive, patients are transported to designated hospitals (including negative pressure ambulances in some cities). All patients, including the mild and asymptomatic, with a positive test are admitted. The designated hospitals are known and are strategically placed with at least one per district/county. Positive cases are cohorted by gender. Negative tested patients are managed based on clinical needs. All patients are evaluated with a respiratory multiplex to look for other diagnoses. This can add to the reassurance that a negative COVID-19 test reflects a lack of infection with COVID-19.

In Wuhan, there are 45 **designated hospitals**, 6 of which are designated for critical patients, and 39 for severe patients and/or any patients >65 years old. There are an additional 10 temporary hospitals reconstructed from gymnasium and exhibition centers, which are for mild patients. Other surge measures undertaken in Wuhan include two new temporary hospitals with 2600 beds, plus many makeshift hospitals to increase bed capacity. Bed capacity within Wuhan has increased to >50,000.

Patients are treated according to the **National Clinical guidelines** (edition 6) released by the China National Health Commission (NHC). There are no specific antiviral or immune modulating agents proven (or recommended) to improve outcomes. All patients are monitored by regular pulse oximetry. The guidelines include supportive care by clinical category (mild, moderate, severe and critical), as well as the role of investigational

treatments such as chloroquine, phosphate, lopinavir/ritonavir, alpha interferon, ribavirin, arbidol. The application of intubation/invasive ventilation and ECMO in critically ill patients can improve survival. The Joint Mission Team was told of ECMO use in four patients at one hospital with one death and three who appeared to be improving. Clearly, though ECMO is very resource consumptive, any health system would need to carefully weigh the benefits. There is widespread use of Traditional Chinese Medicines (TCM), for which the affects must be fully evaluated.

Patients with COVID-19 are not permitted **visitors**. Staff use coveralls, masks, eye cover, and gloves, removing PPE only when they leave the ward.

Patients are discharged after clinical recovery (afebrile >3 days, resolution of symptoms and radiologic improvement) and 2 negative PCR tests taken 24 hours apart. Upon discharge, they are asked to minimise family and social contact and to wear a mask. There are expectations of clinical trial results within a matter of weeks, which will see further opportunities for treatment.

There are guidelines for **elderly care** specifically targeting prevention in individuals and introduction of COVID-19 to nursing homes.

Training programmes by video conference nationally are scaled up to inform staff of best practice and to ensure PPE usage. **Clinical champions** are created to disperse knowledge and provide local expertise.

Maintenance of usual healthcare activities is maintained by hospital zoning (e.g. clean/contaminated sections of the healthcare facility).

Laboratory, diagnostics and virology

The virus found to cause COVID-19 was initially isolated from a clinical sample on 7 January. It is notable that within weeks following the identification of the virus, a series of reliable and sensitive **diagnostic tools** were developed and deployed. On 16 January, the first RT-PCR assays for COVID-19 were distributed to Hubei. Real-time PCR kits were distributed to all the provinces on 19 January and were provided to Hong Kong SAR and Macao SAR on 21 January. Information regarding viral sequences and PCR primers and probes was shared with WHO and the international community by China CDC on 12 January 2020. To facilitate product development and research on the new virus, COVID-19 virus sequences were uploaded to the GISAID Database by China.

By 23 February, there were 10 kits for detection of COVID-19 approved in China by the NMPA, including 6 RT-PCR kits, 1 isothermal amplification kit, 1 virus sequencing product and 2 colloidal gold antibody detection kits. Several other tests are entered in the emergency approval procedure. Currently, there are at least 6 local producers of PCR test kits approved by NMPA. Overall, producers have the capacity to produce and distribute as many as 1,650,000 tests/week.

Specimens from both the upper respiratory tract (URT; nasopharyngeal and oropharyngeal) and lower respiratory tract (LRT; expectorated sputum, endotracheal aspirate, or bronchoalveolar lavage) are collected for COVID-19 testing by PCR.

COVID-19 virus has been detected in respiratory, fecal and blood specimens. According to preliminary data from Guangzhou CDC as of 20 February, virus can initially be detected in upper respiratory samples 1-2 days prior to symptom onset and persist for 7-12 days in moderate cases and up to 2 weeks in severe cases. Viral RNA has been detected in feces in up to 30% of patients from day 5 following onset of symptoms and has been noted for up to 4-5 weeks in moderate cases. However, it is not clear whether this correlates with the presence of infectious virus. While live virus has been cultured from stool in some cases, the role of fecal-oral transmission is not yet well understood. COVID-19 has been isolated from the clinical specimens using human airway epithelial cells, Vero E6 and Huh-7 cell lines.

Serological diagnostics are rapidly being developed but are not yet widely used. Joint Mission members met with local research teams at the China CDC, Guangzhou Regenerative Medicine and Health Guangdong Laboratory. The teams reported on the development of tests for IgM, IgG and IgM+IgG using rapid test platforms utilizing chemiluminiscence. ELISA assays are also under development.

Research & Development

The government of China has initiated a series of major emergency research programs on virus genomics, antivirals, traditional Chinese medicines, clinical trials, vaccines, diagnostics and animal models. Research includes fundamental basic research and human subjects research. For the purpose of this report, human studies are limited to those involving IRB approval and informed consent. Other forms of human subjects investigations are included in the sections on epidemiology in this report. Well-focused, robust research conducted in the setting of an outbreak has the potential of saving many lives by identifying the most effective ways to prevent, diagnose and treat disease.

Since the COVID-19 virus has a genome identity of 96% to a bat SARS-like coronavirus and 86%-92% to a pangolin SARS-like coronavirus, an animal source for COVID-19 is highly likely. This was corroborated by the high number of RT-PCR positive environmental samples taken from the Huanan Seafood Market in Wuhan.

At least 8 **nucleic acid-based methods** for direct detection of COVID-19 and two colloidal gold antibody detection kits have been approved in China by the NMPA. Several other tests are close to approval. It will be important to compare the sensitivities and specificities of these and future serologic tests. Development of rapid and accurate **point-of-care tests** which perform well in field settings are especially useful if the test can be incorporated into presently commercially available multiplex respiratory virus panels. This would markedly improve early detection and isolation of infected patients and, by extension, identification of contacts. **Rapid IgM and IgG antibody testing** are also important ways to facilitate early diagnosis. Standard serologic testing can be used for retrospective diagnoses in the context of serosurveys that help better understand the full spectrum of COVID-19 infection.

A variety of **repurposed drugs and investigational drugs** have been identified. Screening NMPA approved drug libraries and other chemical libraries have identified novel agents. Hundreds of clinical trials involving remdesivir, chloroquine, favipiravir, chloroquine, convalescent plasma, TCM and other interventions are planned or underway. Rapid completion of the most important of these studies is critical to identifying truly effective therapies. However, evaluation of investigational agents requires adequately powered, randomized, controlled trials with realistic eligibility criteria and appropriate stratification of patients. It is important for there to be a degree of coordination between those conducting studies within and beyond China.

The development of a safe and effective **vaccine** for this highly communicable respiratory virus is an important epidemic control measure. Recombinant protein, mRNA, DNA, inactivated whole virus and recombinant adenovirus vaccines are being developed and some are now entering animal studies. Vaccine safety is of prime concern in the area of coronavirus infection in view of the past experience of disease enhancement by inactivated whole virus measles vaccine and similar reports in animal experiments with SARS coronavirus vaccines. It will be important that these vaccine candidates rapidly move into appropriate clinical trials.

The ideal **animal model** for studying routes of virus transmission, pathogenesis, antiviral therapy, vaccine and immune responses has yet to be found. The ACE2 transgenic mouse model and Macaca Rhesus model are already used in research laboratories. Systematically addressing which models can accurately mimic human infection is required.

There is a global rush for masks, hand hygiene products and other personal protective equipment. The relative importance of **non-pharmaceutical control measures** including masks, hand hygiene, and social distancing require further research to quantify their impact.

There are distinct patterns of intra-familial transmission of COVID-19. It is unclear whether or not there are host factors, including genetic factors, that influence susceptibility or disease course. COVID-19 has a varied clinical course and a precise description of that course is not available. In addition, the long-term consequences of COVID-19 are unknown. An observational cohort study of patients with COVID-19 enrolled from the time of diagnosis (with appropriate controls) could provide in-depth information about clinical, virologic and immunologic characteristics of COVID-19. Table 1 summarizes priority research areas with immediate to longer term goals.

Table 1 Priority research areas with immediate, intermediate and longer-term goals

Immediate Goals	Intermediate Goals	Long-term goals
Diagnostics: RNA assays, antibody & antigen assays, point of care detection	Diagnostics: Multiplex diagnostic platforms	Diagnostics: Prognostic markers
Therapeutics: Remdesivir, favipiravir, chloroquine, plasma, TCM	Therapeutics: intravenous immunoglobulin (IVIg)	Therapeutics: Innovative approaches (CRISPR-CAS; RNAi; Cell-based; positive hits from library screening)
Vaccines: Development of animal models	Vaccines: mRNA candidates and candidate viral vectors	Vaccines: inactivated candidates and subunit candidates

D. Knowledge Gaps

Knowledge gaps and key questions to be answered to guide control strategies include:

Source of infection

- Animal origin and natural reservoir of the virus
- Human-animal interface of the original event
- Early cases whose exposure could not be identified

The pathogenesis and virulence evolution of the virus

Transmission dynamics

- Modes of Transmission:
    - Role of aerosol transmission in non-health care settings
    - Role of fecal-oral transmission
- Viral shedding in various periods of the clinical course in different biological samples (i.e. upper and lower respiratory tract, saliva, faeces, urine)
    - Before symptom onset and among asymptomatic cases
    - During the symptomatic period
    - After the symptomatic period / during clinical recovery

Risk factors for infection

- Behavioral and socio-economic risk factors for infection in
    - Households / institutions
    - the Community
- Risk factors for asymptomatic infection
- Risk factors for nosocomial infection
    - among health care workers
    - among patients

Surveillance and monitoring

- Monitoring community transmission through existing
    - ILI surveillance
    - SARI surveillance
- The outbreak trend and intervention dynamics
    - Basic reproduction numbers in various stages of the epidemic
    - The epidemic's relation to seasonality

Laboratory and diagnostics

- Sensitivity and specificity of different nucleic acid (PCR, NAATs and rapid tests), antibody and antigen tests
- Post-infection antibody titers and the duration of protection
- Sero-prevalence among
    - Health care workers
    - General population
    - Children

Clinical management of severe and critically ill patients

- Value of ECMO in the management of critically ill patients
- Best practice using mechanical ventilation in the management of critically ill patients
- Re-evaluation of the role of steroids in the management of severe and critically ill patients
- Identification of factors associated with successful clinical management and outcome
- Determination of the effectiveness of Traditional Chinese Medicines (TCM)
- Determination the effectiveness of additional investigational treatment options (e.g. intravenous immunoglobulin/IVIg, convalescent plasma)

Prevention and control measures

- Key epidemic indicators that inform evidence-based control strategy decision making and adjustments
- Effectiveness of infection prevention and control (IPC) measures in various health care settings
- Effectiveness of entry and exit screening
- Effectiveness of the public health control measures and their socio-economic impact
    - Restriction of movement
    - Social distancing
    - School and workplace closures
    - Wearing mask in general public
    - Mandatory quarantine
    - Voluntary quarantine with active surveillance

E. Operational & Technical Recommendations

Operational/programmatic recommendations

- Reassess risk and capacities based on different stages of the outbreak; approve different measures during the different phases of the response; assess different stages of the response; reach a balance between response and social development
- Initiate a timely scientific evidence based, efficient and flexible joint multi-sectoral mechanism, which is driven by strong government leadership

Technical recommendations

Epidemiology and transmission

- Continue enhanced surveillance across the country through existing respiratory disease systems, including ILI, SARI or pneumonia surveillance systems
- Prioritize early investigations, including household transmission studies, age-stratified sero-epidemiologic surveys including children, case-control studies, cluster investigations, and serologic studies in health care workers

Severity

- Continue to share information on patient management, disease progression and factors leading to severe disease and favorable outcomes
- Review and analyze the possible factors associated with the disease severity, which may include:
    - natural history studies to better understand disease progression in mild, severe and fatal patients
    - medical chart reviews about disease severity among vulnerable groups, (e.g. those with underlying conditions, older age groups, pregnant women and children) to develop appropriate standards of care
    - evaluation of factors leading to favorable outcomes (e.g. early identification and care)

Clinical care and infection prevention and control

- Suspect patients who have not yet been tested should be isolated in single normal pressure rooms; cohorting of positive cases is acceptable
- Physicians and all health care workers need to maintain a high level of clinical alert for COVID-19
- For affected countries, standardize training for clinical care and IPC and scale with the development of local (e.g. district level) experts
- Ensure concurrent testing for other viral pathogens to support a negative COVID-19 test
- Ensure maintenance of usual and essential services during the outbreak

- Ensure processes are in place for infection prevention among the most vulnerable, including the elderly
- Ensure readiness to provide clinical care and to meet IPC needs, including:
    a. anticipated respiratory support requirements (e.g. pulse oximeters, oxygen, and invasive support where appropriate)
    b. national guidelines for clinical care and IPC, revised for COVID-19
    c. nationally standardised trainings for disease understanding and PPE use for HCWs
    d. community engagement
    e. PPE and Medication stockpiles
    f. early identification protocols; triage, temperature screening, holding bays (triage, including pulse oximetry)
    g. treatment protocols including designated facilities, patient transportation
    h. enhanced uptake of influenza and pneumococcal vaccine according to national guidelines
    i. laboratory testing
    j. rapid response teams

Laboratory and virology

- Continue to perform whole genome analysis of COVID-19 viruses isolated from different times and places, to evaluate virus evolution
- Conduct pathogenesis studies using biopsy/post-mortem specimens of COVID-19 patients or infected animal models
- Evaluate available nucleic acid PCR diagnostics
- Rapidly develop and evaluate rapid/point-of-care diagnostics and serologic assays
- Conduct further study to interpret the result of positive COVID-19 RNA detection in feces in patients recovering from COVID-19
- Enhance international cooperation, especially in terms of biosafety and information sharing for increased understanding of the COVID-19 virus and traceability of the virus
- Consider monitoring proinflammatory cytokines via multiplex assays to predict the development of “cytokine storm”

Research and development

- Additional effort should be made to find the animal source, including the natural reservoir and any intermediate amplification host, to prevent any new epidemic foci or resurgence of similar epidemics

- Efforts should be made to consistently evaluate existing and future diagnostic tests for detection of COVID-19 using a harmonized set of standards for laboratory tests and a biorepository that can be used for evaluating these tests
- Consider the establishment of a centralized research program in China to oversee that portfolio and ensure the most promising research (vaccines, treatments, pathogenesis) are adequately supported and studied first; program staff dedicated to the clinical research would work at the clinical research site(s) to decrease the research workload of the clinicians at the site
- Consider including one or more sites within China in the ongoing and future multi-center, international trials; Chinese investigators should be actively engaged in international trials
- Continue to develop additional animal models, making every effort to ensure these mimic human infection and virus transmission as closely as possible
- Conduct studies to determine which of the commonly used forms of PPE are most effective in controlling the spread of COVID-19

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Epidemiology and transmission of COVID-19 in 391 cases and 1286 of their close contacts in Shenzhen, China: a retrospective cohort study

Summary

Background Rapid spread of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in Wuhan, China, prompted heightened surveillance in Shenzhen, China. The resulting data provide a rare opportunity to measure key metrics of disease course, transmission, and the impact of control measures.

Methods From Jan 14 to Feb 12, 2020, the Shenzhen Center for Disease Control and Prevention identified 391 SARS-CoV-2 cases and 1286 close contacts. We compared cases identified through symptomatic surveillance and contact tracing, and estimated the time from symptom onset to confirmation, isolation, and admission to hospital. We estimated metrics of disease transmission and analysed factors influencing transmission risk.

Findings Cases were older than the general population (mean age 45 years) and balanced between males (n=187) and females (n=204). 356 (91%) of 391 cases had mild or moderate clinical severity at initial assessment. As of Feb 22, 2020, three cases had died and 225 had recovered (median time to recovery 21 days; 95% CI 20–22). Cases were isolated on average 4·6 days (95% CI 4·1–5·0) after developing symptoms; contact tracing reduced this by 1·9 days (95% CI 1·1–2·7). Household contacts and those travelling with a case were at higher risk of infection (odds ratio 6·27 [95% CI 1·49–26·33] for household contacts and 7·06 [1·43–34·91] for those travelling with a case) than other close contacts. The household secondary attack rate was 11·2% (95% CI 9·1–13·8), and children were as likely to be infected as adults (infection rate 7·4% in children <10 years *vs* population average of 6·6%). The observed reproductive number (*R*) was 0·4 (95% CI 0·3–0·5), with a mean serial interval of 6·3 days (95% CI 5·2–7·6).

Interpretation Our data on cases as well as their infected and uninfected close contacts provide key insights into the epidemiology of SARS-CoV-2. This analysis shows that isolation and contact tracing reduce the time during which cases are infectious in the community, thereby reducing the *R*. The overall impact of isolation and contact tracing, however, is uncertain and highly dependent on the number of asymptomatic cases. Moreover, children are at a similar risk of infection to the general population, although less likely to have severe symptoms; hence they should be considered in analyses of transmission and control.

Introduction

Since emerging in Wuhan, China, in December, 2019,[1] the coronavirus disease 2019 (COVID-19) epidemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has progressed rapidly into a pandemic. COVID-19 is characterised by fever, cough, fatigue, shortness of breath, pneumonia, and other respiratory tract symptoms,[2–4] and in many cases progresses to death. As of April 15, 2020, there have been 1914916 confirmed cases and 123010 deaths reported worldwide.[5] Most cases were initially confined to Hubei province in China, but there has since been substantial spread not only elsewhere in China but worldwide. A rapid and robust response by the global scientific community has described many important aspects of SARS-CoV-2 transmission and natural history,[1,2,6–8] but key questions remain.

If well tracked, early introductions of an emerging pathogen provide a unique opportunity to characterise its transmission, natural history, and the effectiveness of screening. Careful monitoring of cases and low probability of infection from the general community enables inferences, important to modelling the course of the outbreak, that are difficult to make during a widely disseminated epidemic. In particular, we can make assumptions about when and where cases were likely to have been infected that are impossible when the pathogen is widespread. Furthermore, during these early phases, uninfected and asymptomatic contacts are often closely tracked, providing important information about transmission and natural history. Combined, these data on early introductions can be used to give insights into the natural history of the disease,[9]

Research in context

Evidence before this study

The emergence of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has been accompanied by a substantial increase in research and publications ranging from transmissibility of SARS-CoV-2 to clinical characteristics of the infection. As of March 23, 2020, our search of PubMed using keywords ("COVID-19" OR "SARS-nCoV-2" OR "novel coronavirus") AND ("serial interval" OR "incubation period" OR "attack rate") yielded 14 articles that have estimated either the serial interval or incubation period of coronavirus disease 2019 (COVID-19) and one that investigated the secondary attack rate. However, most of these estimates have come from either Wuhan or publicly available case data; in both instances, incomplete capture of infections and cases might have produced biased estimates.

Added value of this study

This study is, to our knowledge, the first analysis of SARS-CoV-2 transmission and COVID-19 natural history based on a large primary dataset of cases and close contacts, for which the mode of surveillance (ie, symptom-based versus contact-based) was sufficiently documented and RT-PCR testing was nearly universal. We present one of the first estimates of the serial interval, secondary household attack rate, and dispersion (ie, tendency towards super spreading) for SARS-CoV-2 based on active surveillance data. We found that the attack rate does not differ significantly by age, with on average 7% of close contacts becoming infected, around 80% of these contacts showing any symptoms, and 3% of infections manifesting severe disease at initial assessment. We also found that contact-based surveillance in Shenzhen reduced the duration an infected individual transmits in the community by 2 days. These findings are important for understanding the burden of COVID-19 and for strategic planning across the world.

Implications of all the available evidence

These results shed further light on how SARS-CoV-2 is transmitting, how severe it is, and how effective control measures can be in specific contexts. We provide a key piece of evidence supporting intensive contact tracing and highlighting that children might be an important target for interventions aimed at reducing transmission, even if they do not get sick.

transmission characteristics,[10] and the unseen burden of infection.[11]

Here, we use data collected by the Shenzhen Center for Disease Control and Prevention (Shenzhen CDC) on 391 cases of COVID-19 and 1286 of their close contacts to characterise key aspects of its epidemiology outside of Hubei province. We characterise differences in demographics and severity between cases identified through symptom-based surveillance and monitoring of close case contacts, and estimate the time to key events, such as confirmation, isolation, and recovery. Using data from contact tracing, we characterise SARS-CoV-2 transmission by estimating key values, such as the household secondary attack rate, serial interval, and observed reproductive number (R).

Methods

Case identification

On Jan 8, 2020, Shenzhen CDC identified the first case of pneumonia with unknown cause and began monitoring travellers from Hubei province for symptoms of COVID-19. Over the next 2 weeks this surveillance programme expanded to include travellers from Hubei regardless of symptoms, patients at local hospitals, and individuals detected by fever screening in neighbourhoods and at local clinics. Suspected cases and close contacts were tested for SARS-CoV-2 by RT-PCR of nasal swabs at 28 qualified local hospitals, ten district-level CDCs, and two third-party testing organisations, with final confirmation done at the Guangdong Provincial Center for Disease Control and Prevention (Guangdong CDC) or Shenzhen CDC (appendix 2 p 11). Close contacts were identified through contact tracing of a confirmed case and were defined as those who lived in the same apartment, shared a meal, travelled, or socially interacted with an index case 2 days before symptom onset. Casual

Table 2: **Association of clinical and demographic factors with mode of detection and severity at initial assessment**

contacts (eg, other clinic patients) and some close contacts (eg, nurses) who wore a mask during exposure were not included in this group.

Symptomatic cases were isolated and treated at designated hospitals regardless of RT-PCR test results. Asymptomatic individuals who tested positive were quarantined at centralised facilities. Close contacts and travellers from Hubei who tested negative were quarantined at home or a central facility, and monitored for 14 days. RT-PCR testing was required for all close contacts at the beginning of isolation, and release was conditional on a negative RT-PCR result. Basic demographics, signs and symptoms, clinical severity, and exposure history were recorded for all confirmed cases.

Here, we analyse confirmed cases identified by the Shenzhen CDC between Jan 14 and Feb 12, 2020, and close contacts of cases confirmed before Feb 9, 2020.

This work was done in support of an ongoing public health response, and hence was determined not to be human subjects research after consultation with the Johns Hopkins Bloomberg School of Public Health institutional review board. Data collection is part of the continuing public health investigation of an emerging outbreak and therefore the individual informed consent was waived. The study was approved by the ethics committees of Shenzhen CDC. Analytical datasets were constructed in an anonymised manner, and all analysis of personally identifiable data took place onsite at the Shenzhen CDC.

Epidemiological and clinical characteristics of cases

We defined symptom-based surveillance to include symptomatic screening at airport and train stations, community fever monitoring, home observation of recent travellers to Hubei, and testing of patients admitted to hospital. Contact-based surveillance is the identification of cases through monitoring and testing of close contacts of confirmed cases, independently of their symptom presentation. By protocol, those in the contact-based group were tested for SARS-CoV-2 infection regardless of symptoms, whereas those in the other categories were tested only if they showed signs or symptoms of disease.

At the first clinical assessment, data were recorded on 21 signs and symptoms (appendix 2 p 1), and disease severity was assessed. Cases with fever, respiratory symptoms, and radiographic evidence of pneumonia were classified as having moderate symptoms. Cases

were classified as having severe symptoms if they had any of the following: breathing rate 30 breaths per min or higher; oxygen saturation level 93% or lower at rest; oxygen concentration level PaO_2/FiO_2 (ratio of arterial oxygen partial pressure to fractional inspired oxygen) 300 mm Hg (1 mm Hg=0·133 kPa) or lower; lung infiltrates higher than 50% within 24–48 h; respiratory failure requiring mechanical ventilation; septic shock; or multiple organ dysfunction or failure. All other symptomatic cases were classified as mild.

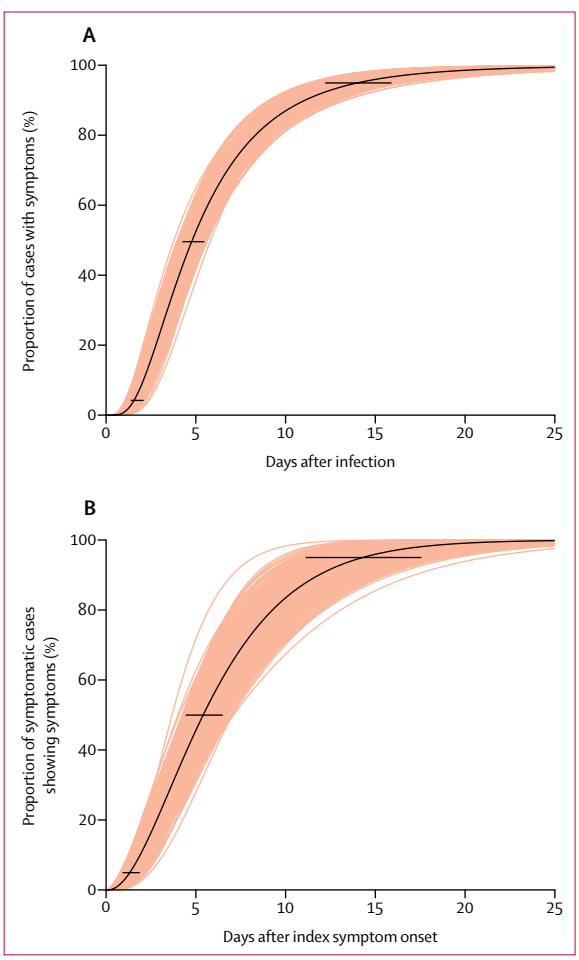

Figure 1: **Incubation period and serial interval of COVID-19**
(A) Proportion of cases who developed symptoms of coronavirus disease 2019 (COVID-19) by days after infection (ie, the cumulative distribution function of the incubation period). (B) Proportion of cases infected by an index case who developed symptoms by a given number of days after the day of symptom onset of the index case (ie, the cumulative distribution function of the serial interval). The maximum-likelihood estimates for the parametric distribution of the cumulative distribution function are shown, along with 1000 parametric bootstrap estimates of the cumulative distribution function. The median incubation period of COVID-19 is estimated to be 4·8 days (95% CI 4·2–5·4). 5% of cases who develop symptoms will do so by 1·6 days (95% CI 1·3–2·0) after infection, and 95% by 14·0 days (12·2–15·9). We estimated that the median serial interval of COVID-19 is 5·4 days (95% CI 4·4–6·5). 5% of infected cases who develop symptoms will do so by 1·3 days (95% CI 0·9–1·9) after symptom onset of the index case, and 95% by 14·3 days (11·1–17·6).

Relationships between demographics, mode of detection, and symptom severity were assessed and characterised with χ^2 tests, and simple and multiple logistic regression.

Timing of key events

Distributions were fit to the timing of key events in each confirmed case's course of infection and treatment. The time from infection to symptom onset (incubation period) was assumed to be log-normally distributed and estimated as previously described.[12–14] We determined the left and right boundaries on the possible exposure and symptom onset times. Cases who recently travelled to Hubei were assumed to have been exposed while there. Cases without a recent travel history but with exposure to a confirmed case were assumed to be exposed from the time of earliest to latest possible contact with that case. Only cases for whom we could identify the earliest and latest possible time of exposure and who had a date of symptom onset were included in the analysis.

Time between symptom onset and recovery was estimated by use of parametric survival methods. Patients who had not recovered were considered to be censored on Feb 22, 2020, or at the time of death. All other delay distributions were estimated by directly fitting parametric distributions to time between symptom onset or arrival in Shenzhen, and confirmation, isolation, or admission to hospital. Confidence intervals were calculated with bootstrapping or standard parametric estimators.[15]

Transmission characteristics

Transmission was characterised by examining the relationship between confirmed cases and their infected and uninfected close contacts. The household secondary attack rate was calculated as the percentage of household contacts (those sharing a room, apartment, or other sleeping arrangement) who were later confirmed to have SARS-CoV-2 infection. The distribution of serial intervals (the time between symptom onset in the confirmed case and their infected contacts) was calculated by fitting parametric distributions to the time of symptom onset in clear case–contact pairs. The mean R and distribution of individual reproductive numbers (ie, the number of secondary infections caused by each case) were calculated from the number of secondary infections observed among close contacts of each index case, with ambiguities resolved through multiple imputation (appendix 2 p 11). The relative odds of transmission among contacts of various types were estimated by use of conditional logistic regression and random-effects models, to account for differing numbers of possible infected individuals in each risk group. When assessing the impact of characteristics of infected individuals, we only included risk sets where a single potential infected individual was clearly identifiable. Confidence intervals were estimated by use of bootstrapping or standard parametric approaches.

Role of the funding source

The sponsor of the study had no role in study design, data collection, data analysis, data interpretation, or writing of the report. Shenzhen CDC had full access to all the data in the study, and all corresponding authors share the final responsibility for the decision to submit for publication.

Results

Between Jan 14 and Feb 12, 2020, the Shenzhen CDC confirmed 391 cases of SARS-CoV-2 infection (table 1). Of 379 with a known mode of detection, 292 (77%) were detected through symptom-based surveillance. Overall, there were approximately equal numbers of male and female cases (187 *vs* 204). The mean age of the population was 45 years, and 307 (79%) of 391 cases were adults aged 30–69 years. At the time of first clinical assessment, most cases were mild (102 [26%] of 391) or moderate (254 [65%] of 391), and only 35 (9%) were severe. 330 (84%) of 391 cases had fever at the time of initial assessment, while 25 (6%) of 391 had no signs or symptoms. As of Feb 22, 2020, final clinical outcomes were known for 228 of 391 cases in our data, with three who had died (all captured through symptom-based surveillance) and 225 who had recovered.

A larger proportion of cases detected through symptom-based surveillance were male (161 [55%] of 292 *vs* 24 [28%] of 87) and aged 20–69 years (266 [91%] of 292 *vs* 65 [75%] of 87) than were those detected through contact-based surveillance (tables 1, 2). At the time of the first clinical assessment, 25 (29%) of 87 cases in the contact-based surveillance group did not have fever, and 17 (20%) of 87 had no symptoms. By contrast, 258 (88%) of 292 in the symptom-based surveillance group had fever, and only eight reported no symptoms.

In multiple logistic regression, male sex was associated with severe symptoms (odds ratio [OR] 2·5 [95% CI 1·1–6·1]). The probability of severe symptoms increased slightly with age, although only individuals aged 60–69 years had a significantly increased risk compared with the reference category, individuals aged 50–59 years (OR 3·4 [95% 1·4–9·5]).

Based on 183 cases with a well defined period of exposure and symptom onset (appendix 2 p 8), we estimated the median incubation period for COVID-19 to be 4·8 days (95% CI 4·2–5·4; figure 1, appendix 2 p 2),

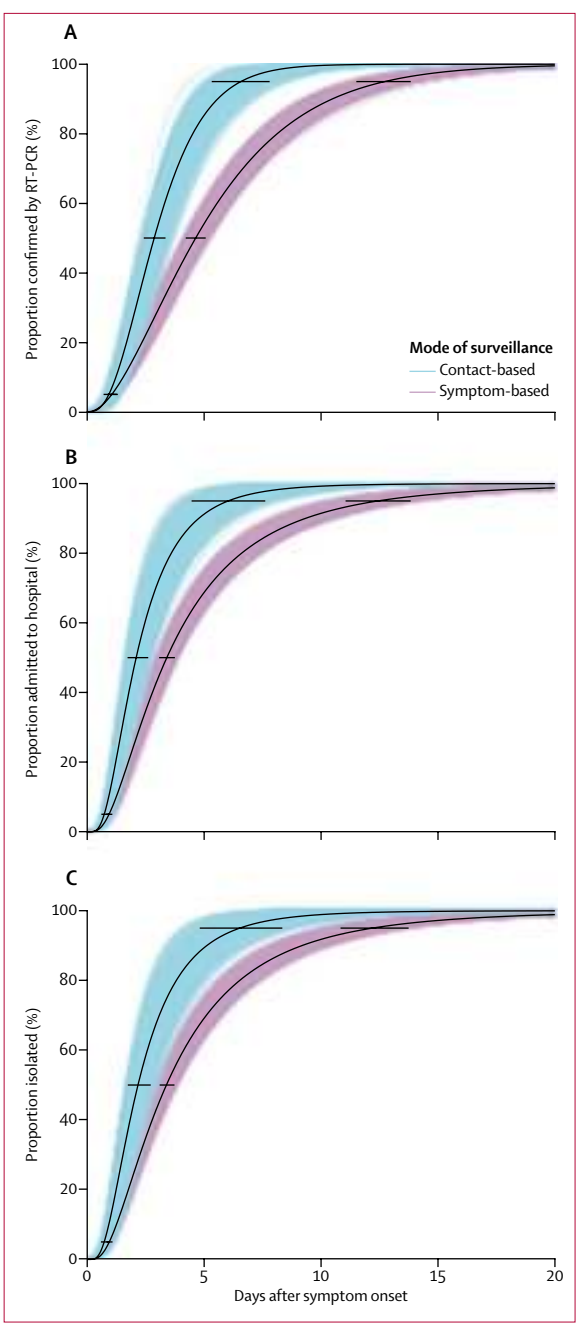

Figure 2: **Time between symptom onset and SARS-CoV-2 confirmation (A), admission to hospital (B), and isolation among cases (C) detected by contact-based and symptom-based surveillance**

The maximum-likelihood estimates for the parametric distribution of the cumulative distribution function are shown, along with 1000 parametric bootstrap estimates of the cumulative distribution function. Panel A shows estimates of the proportion of cases who are confirmed by RT-PCR, according to the number of days after symptom onset. We estimated that 50% of cases detected through symptom-based surveillance were confirmed by RT-PCR within 4·6 days (95% CI 4·2–5·0) after symptom onset, and 95% were confirmed by RT-PCR within 12·7 days (11·5–13·8) after symptom onset. Contact-based surveillance reduced the days from symptom onset to RT-PCR confirmation to 2·9 days (95% CI 2·4–3·4) in 50% of cases and to 6·6 days (5·3–8·0) in 95% of cases. Panel B shows estimates of the proportion of cases who were admitted to hospital, according to the number of days after symptom onset. We estimated that 50% of the cases detected through symptom-based surveillance were admitted to hospital by 3·4 days (95% CI 3·1–3·8) after symptom onset, and 95% by 12·4 days (10·9–13·8). Contact-based surveillance reduced the days from symptom onset to hospital admission to 2·1 days (95% CI 1·7–2·6) in 50% of cases, and 6·0 days (95% CI 4·5–7·5) in 95% of cases. Panel C shows estimates of the proportion of cases isolated, according to number of days after symptom onset. We estimated that 50% of cases detected through symptom-based surveillance were isolated by 3·4 days (95% CI 3·1–3·7) after symptom onset, and 95% by 12·2 days (95% CI 10·8–13·6). Contact-based surveillance reduced the days from symptom onset to isolation to 2·2 days (95% CI 1·7–2·6) in 50% of cases, and to 6·5 days (4·7–8·2) in 95% of cases.

SARS-CoV-2=severe acute respiratory syndrome coronavirus 2. Inf=infinity. *15 confirmed close contacts were excluded from this analysis because contact tracing reports for the negative close contacts in the same clusters were missing. Close contacts with missing data on sex, age, contact types, or contact frequency not shown.

Table 3: **Group-specific attack rates and risk factors for SAR-CoV-2 infection among close contacts**

and estimated that 95% of those who develop symptoms will do so within 14·0 days (95% CI 12·2–15·9) of infection. We estimated that about 5·0% of cases who develop symptoms would not show symptoms until 14 days after infection.

Based on 228 cases with known outcomes, we estimated that median time to recovery was 20·8 days (95% CI 20·1–21·5). We estimated that the median time to recovery was 22·4 days (95% CI 20·8–24·1) in individuals aged 50–59 years, and was estimated to be significantly shorter in younger adults (eg, 19·2 days in individuals aged 20–29 years; appendix 2 pp 3, 10). In multiple regression models including sex, age, baseline severity, and method of detection, in addition to age, baseline severity was associated with time to recovery (appendix 2 p 3). Compared to cases with mild symptoms, those with severe symptoms had a 41% (95% CI 24–60) longer time to recovery (appendix 2 p 3). As of Feb 22, 2020, three cases had died. These deaths occurred 35–44 days from symptom onset and 27–33 days from confirmation.

Cases detected through symptom-based surveillance were confirmed on average 5·5 days (95% CI 5·0–5·9) after symptom onset (figure 2, appendix 2 p 2), whereas those detected by contact-based surveillance were confirmed on average 3·2 days (95% CI 2·7–3·8) after symptom onset. 17 (5%) of 342 cases with a known onset date and start date of quarantine were isolated before developing symptoms. Among those isolated after developing symptoms, the symptom-based surveillance group was, on average, isolated 4·6 days (95% CI 4·1–5·0) after symptom onset, whereas the contact-based surveillance group was isolated 2·7 days (2·1–3·3) after symptom onset. Hence, contact-based surveillance was associated with a 2·3-day (95% CI 1·5–3·0) decrease in time to confirmation and a 1·9-day (1·1–2·7) decrease in time to isolation. The mean time between symptom onset and admission to hospital was similar to time between symptom onset and isolation in both the symptom-based and contact-based surveillance groups (figure 2, appendix 2 p 2).

191 (64%) of 298 travellers developed symptoms after arriving in Shenzhen, with a mean time from arrival to symptom onset of 4·9 days (95% CI 4·2–5·5; appendix 2 p 2). Those developing symptoms before arrival or on the day of arrival were confirmed as cases on average 4·5 days (95% CI 3·8–5·1) after arrival, and isolated on average 3·1 days (2·5–3·7) after arrival.

Overall, 1286 close contacts were identified for index cases testing positive for SARS-CoV-2 between Jan 14 and Feb 9, 2020, with 244 (84%) of 292 cases having at least one close contact. 622 (95%) of 653 close contacts with known dates for the period when they were under quarantine were followed up for 12 days or longer. 98 of the close contacts tested positive for SARS-CoV-2 infection by RT-PCR, and one had presumptive infection. Assuming those with a missing test result were uninfected, we found that the secondary attack rate was 11·2% (95% CI 9·1–13·8) among household contacts and 6·6% (5·4–8·1) overall (the secondary attack rate increased to 14·9% [12·1–18·2] among household contacts and 9·7% [7·9–11·8] overall if those with missing results were removed from the denominator). In multiple conditional logistic regression analysis of contact types, household contact (OR 6·3; 95% CI 1·5–26·3) and travelling together (OR 7·1; 1·4–34·9) were significantly associated with infection (table 3). Reporting contact that occurred often was also associated with increased risk of infection compared with moderate-frequency contact (OR 8·8; 95% CI 2·6–30·1; table 3).

Attack rates were similar across all age categories of infected contacts (table 3), although we observed some indication of elevated attack rates in older age groups (figure 3). Notably, the rate of infection in children younger than 10 years (7·4%) was similar to the population average (6·6%). There was no significant association between probability of infection and age of the index case. Surprisingly, in univariate analysis a longer time in the community before isolation was associated with a reduced risk of causing infections (data not shown). However, this association was no longer significant after adjusting for contact frequency and type.

Based on 48 pairs of cases with a clear relationship between the index case and secondary case and time of symptom onset, we estimated that the serial interval is gamma distributed with a mean of 6·3 days (95% CI 5·2–7·6) and an SD of 4·2 days (95% CI 3·1–5·3; figure 1B, appendix 2 p 2). Hence, 95% of secondary cases were expected to develop symptoms within 14·3 days (95% CI 11·1–17·6) of their infector. This estimate includes the effect of isolation on truncating the serial interval. Stratified results show that if the infected individual was isolated less than 3 days after infection the average serial interval was 3·6 days, increasing to 8·1 days if the infected individual was isolated on the third day after symptom onset or later (appendix 2 p 3).

The mean number of secondary cases caused by each index case (ie, the observed reproductive number, *R*), was 0·4 (95% CI 0·3–0·5). The distribution of individual *R* values was highly over-dispersed, with 80% of infections being caused by 8·9% (95% CI 3·5–10·8) of cases (negative binomial dispersion parameter 0·58; 95% CI 0·35–1·18).

We examined the potential impact of surveillance and isolation through truncating the infectious period.

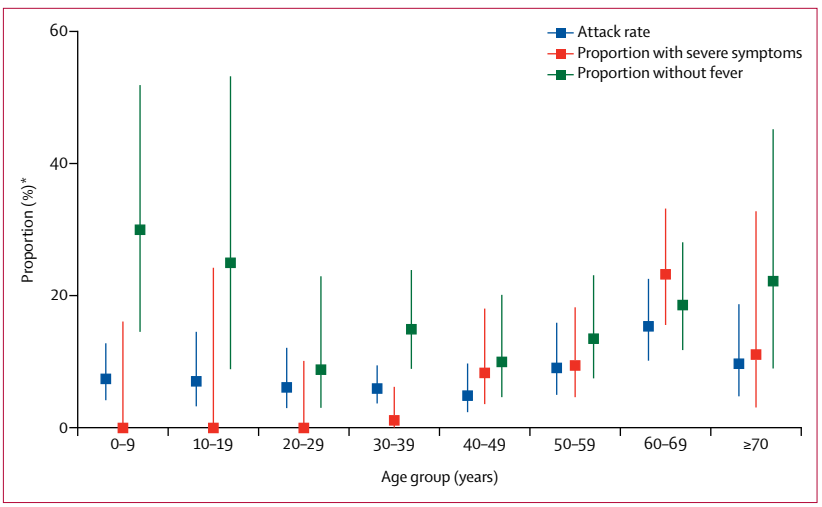

Figure 3: **Attack rate among close contacts, baseline severity, and proportion of cases without fever at initial assessment by age group**

*Proportion of close contacts for attack rate; proportion of all cases for those with severe symptoms or no fever at initial assessment.

Because of the scarce understanding of infectious periods following SARS-CoV-2 infection, we considered a range of possible infectious periods where infectiousness varies over time and follows a gamma distribution (appendix 2 p 11). We defined the mean infectious day (ie, the average number of days after symptom onset that an infected individual is expected to infect a secondary case) as the weighted mean of the infectious period, where each day is weighted by relative infectiousness. We considered periods where the mean infectious day is less than 15 days after symptom onset (roughly the period of SARS and early SARS-CoV-2 reports),[16,17] and assumed that R_0=2·6 and that isolation effectively ends the infectious period. Under these assumptions we found that if the mean infectious day is greater than 5 days, then it might be possible to bring *R* below one in cases detected by symptom-based surveillance, and the same can be accomplished by contact-based surveillance if the mean infectious day is greater than 3 days (appendix 2 p 9). For the impact of passive surveillance alone to achieve our observed *R* of 0·4, we projected that the mean infectious day must be at least 5·5 days (and likely greater) after symptom onset.

Even if transmission is completely eliminated in the group captured by surveillance (eg, if we could get perfect surveillance on the day of symptom onset), assuming R_0=2·6, the cases captured by surveillance must, if not isolated, be expected to cause 61% of onward transmission to achieve local elimination by surveillance and isolation alone (appendix 2 p 9).

Discussion

This analysis of early SARS-CoV-2 cases and their close contacts in Shenzhen, China, provides insight into the natural history, transmission, and control of this disease.

The values estimated provide the evidentiary foundation for predicting the impact of this virus, evaluating control measures, and guiding the global response. Analyses of how cases are detected, and use of data on individuals exposed but not infected, indicate that infection rates in young children are not lower than the population average (even if rates of clinical disease are). We were able to directly estimate important transmission parameters, and show that, at least among observed contacts, transmission rates are low. Estimates of the distribution of time between symptom onset and case isolation by surveillance type reveal that heightened surveillance combined with case isolation could plausibly account for these low rates of transmission. These results paint a positive picture of the impact of heightened surveillance and isolation in Shenzhen. However, uncertainty in the number of asymptomatic cases missed by surveillance and their ability to transmit SARS-CoV-2 must temper any hopes of stopping the COVID-19 pandemic by these measures.

This work further supports the understanding of COVID-19 as a disease with a fairly short incubation period (mean 4–6 days) but a long clinical course,[2,7,18] with patients taking many weeks to die or recover. Notably, however, we estimate a higher proportion of cases taking 14 days or more to develop symptoms (5%) than estimated in the study by Lauer and colleagues (1%).[6]

Focusing on cases detected through contact-based surveillance adds nuance to previous characterisations of COVID-19. Since RT-PCR testing of contacts is near universal, we can assume these cases are more reflective of the average SARS-CoV-2 infection than cases detected through symptomatic surveillance. In the contact-based surveillance group, any tendency for cases to be male or older (beyond the underlying population distribution) disappears. Furthermore, in this group, 20% of cases were asymptomatic at the time of first clinical assessment and nearly 30% did not have a fever. This observation is consistent with a reasonably high rate of asymptomatic carriage, but lower than that suggested by some modelling studies,[19] although RT-PCR has imperfect sensitivity.[20]

In Shenzhen, SARS-CoV-2 transmission most probably occurred between very close contacts, such as individuals sharing a household. However, even in this group fewer than one in six contacts (ie, secondary attack rate 11–15%) were infected, and overall we observed far fewer than one (0·4) onward transmission per primary case. As noted above, low transmission levels might in part be due to the impact of isolation and surveillance, but it is equally likely that unobserved transmission has some role. We also estimated reasonably high rates of overdispersion in the number of cases caused by each infected individual, leaving open the possibility that large COVID-19 clusters can occur even if surveillance and isolation are forcing R below one—events that could potentially overwhelm the surveillance system.

This work has numerous limitations. As in any active outbreak response, the data were collected by multiple teams under protocols that, by necessity, changed as the situation developed. Hence, there might be noise and inconsistency in definitions. Notably, the definition of a confirmed case changed to require symptoms near the end of our analysis period (Feb 7), but sensitivity analyses show that truncating the data at this point does not qualitatively influence results (appendix 2 pp 5–6). It is, likewise, impossible to identify every potential contact an individual has, so contact tracing focuses on those close contacts who are most likely to be infected; hence our R is assuredly lower than the true reproductive number in the population. Asymptomatic travellers will be missed by symptom-based surveillance and, even if they are tested, some asymptomatic contacts might be missed because of the imperfect sensitivity of the RT-PCR test.[20] Recovery time in Shenzhen is likely to be inflated because cases are required to be isolated for 2 weeks and release is conditional on a negative RT-PCR test. Although guidelines for contact tracing and case detection are supposed to be implemented across the country, whether the impact of contact tracing can be generalised to other parts of China depends on a range of factors, including local testing capacity and surveillance resources.

As SARS-CoV-2 continues to spread, it is important that we continue to expand our knowledge about its transmission and natural history. Data from the early phase of local outbreaks, when detailed contact tracing is possible and sources of infection can still be reliably inferred, are particularly powerful for estimating critical values pertinent to describing transmission and the natural history of a disease. This is especially true when information about uninfected contacts and mode of detection is used, as we have done here. The resulting estimates provide important inputs for interpreting surveillance data, evaluating interventions, and setting public health policy.

CANADA COVID-19 WEEKLY EPIDEMIOLOGY REPORT

28 MARCH TO 03 APRIL 2021 (WEEK 13)

Published: 09 April 2021

39 639 (↑28%) New cases reported in the last 7 days[a]	**195 (↓8%)** New deaths reported in the last 7 days[a]
5 663 (↑28%) Average number of cases reported daily in the last 7 days[a]	**28 (↓8%)** Average number of deaths reported daily in the last 7 days[a]
115 653 (↑6%) Average number of tests performed daily in the last 7 days[b]	**5.1% (↑0.8)** Percentage of positive tests in the last 7 days[b]

[a]Source: Provincial and Territorial Ministry of Health (MOH) websites as of 03 April 2021

[b]Source: National Microbiology Laboratory (NML) data for laboratory analyses as of 03 April 2021

Note: The percentages are calculated based on the difference in the total number of cases, deaths, or tests in the past 7 days compared to the prior 7 days, divided by the number of cases, deaths, or tests in the prior 7 days. The change in the percentage of positive tests is based on the difference in percentage points compared to the previous week.

KEY MESSAGES

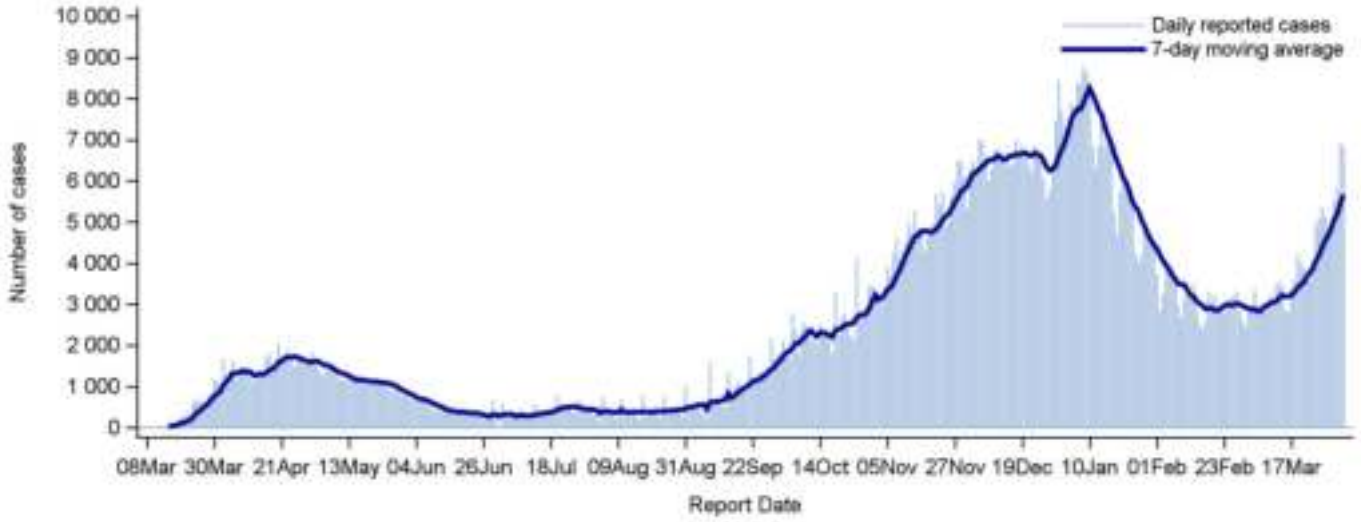
- In Canada, there was an average of **5 663 new cases reported daily** during the week of 28 March to 03 April (week 13), representing a **28% increase** compared to the previous week (week 12: 21 March to 27 March).
- British Columbia, Alberta, Saskatchewan, Ontario, Québec and Newfoundland and Labrador reported **increases in weekly numbers**, compared to the previous week.
- **Daily rates of cases per 100 000 population have increased among most age groups during the past week**. Among both males and females, case rates remain highest among individuals in the 20 to 39 year age group and lowest among individuals in the 80 years and older age group.
- **Long-term care facilities and retirement residences** continue to be the most commonly reported outbreak setting in Canada, and account for the greatest proportion of outbreak related cases and deaths.
- During week 13, **an average of 115 653 tests were performed daily** for COVID-19 across Canada. The weekly percentage of tests positive was **5.1%**, an increase from the previous week.
- There was an average of **28 new deaths reported daily** during week 13, representing an **8% decrease** compared to the previous week.
- **The number of hospitalizations and ICU admissions increased during week 13**. On 03 April 2021, there were 2 250 cases hospitalized and 801 cases in ICU, representing a 5% increase in the seven-day moving average of hospitalized cases and a 16% increase in the seven-day moving average of ICU admissions compared to one week prior.
- The overall cumulative hospitalization rate (including ICU admissions) is 139 cases per 100 000 population, with **the highest rates observed among those aged 80 years and older** (1 013 cases per 100 000 population).
- According to forecasting, between **1 093 510 to 1 150 910 cumulative reported cases** and **23 290 to 23 710 cumulative reported deaths** are expected by 18 April 2021.

NATIONAL DEMOGRAPHICS AND TRENDS

NATIONAL TRENDS IN CASES

- During week 13, a total of 39 639 cases of COVID-19 were reported in Canada, an average of 5 663 cases per day.
- The number of new cases represents a 28% increase compared to week 12.
- Since early March 2021, the number of new cases reported has consistently increased, with 6 822 new cases reported on 03 April 2021 (Figure 1).

Figure 1. Daily number of reported COVID-19 cases in Canada (and 7-day moving average), as of 03 April 2021 (N= 1 001 658)



Source: Provincial and Territorial MOH websites as of 03 April 2021

Note: The 7-day moving average is a trend indicator that captures the arithmetic mean of the daily reported cases over the previous seven days. The moving average helps smooth out day-to-day variability in reporting, filtering out the "noise" of short-term fluctuations. Fluctuations can be attributed to retrospective data, non-reporting on the weekends or provinces or territories reporting cases at a reduced frequency. Spikes in cases may be due to regular reporting variations (e.g. lower reporting on weekends or holidays), or periodic reporting of previous cases by provinces and territories.

Most provinces and territories, with the exception of Northwest Territories and Nunavut, reported new cases during week 13 (Table 1):

- The weekly number of new cases decreased in Manitoba, New Brunswick, Nova Scotia and Prince Edward Island, compared to the previous week. No change was observed in Yukon.
- The weekly number of new cases increased in British Columbia, Alberta, Saskatchewan, Ontario, Québec and Newfoundland and Labrador, compared to the previous week.
- Cases increased by 31% in Ontario and 33% in Québec, compared to the previous week. Together, these provinces accounted for about 64% of the cases reported during week 13.
- Cumulatively, Ontario reported the highest number of cases (n=358 558), while Québec has the highest incidence rate at 3 673.2 cases per 100 000 population.

Table 1. Trends of new cases in Canada and by province or territory, as of 03 April 2021

Province/Territory	Total number of cases (as of 03 April)[a]	Average number of cases reported daily (week 13)	Weekly number of cases reported		Percent change (%)[b]	Crude rate per 100 000 population (as of 03 April)
			21 March to 27 March (week 12)	28 March to 03 April (week 13)		
British Columbia	103 031	917	5 271	6 418	22%	2 001.5
Alberta	151 359	809	4 317	5 663	31%	3 423.0
Saskatchewan	34 323	220	1 324	1 540	16%	2 912.0
Manitoba	34 352	69	604	485	-20%	2 490.6
Ontario	358 558	2 552	13 609	17 866	31%	2 433.5
Québec	314 958	1 081	5 703	7 564	33%	3 673.2
Newfoundland and Labrador	1 020	1	1	5	400%	195.4

Source: Provincial and Territorial MOH websites as of 03 April 2021

[a] The number of cases includes the total confirmed and probable cases.

[b] The percentage is calculated based on the difference in the total number of cases in the past 7 days compared to the prior 7 days divided by the number of cases in the prior 7 days. Note that for provinces/territories with low case counts, an increase or decrease of only a few cases leads to a large percentage change. If the denominator is zero, the percent change cannot be calculated.

[c] Includes 13 cases identified in repatriated travelers (Grand Princess Cruise ship travelers) who were under quarantine in Trenton in March 2020.

Age-standardized rates take into account the differences in population size and age structure between provinces and territories to allow for more valid comparisons of COVID-19 spread in Canada.

Table 2 presents the age-standardized incidence rate by province or territory during week 13.

- Saskatchewan reported the highest age-standardized incidence rate (127.4 cases per 100 000 population).
- The second and third-highest age-standardized incidence rates were reported by Ontario (126.3 cases per 100 000 population) and British Columbia (125.2 cases per 100 000 population).

Table 2. Age-standardized incidence rates by province or territory for week 13

Province/Territory	Age-standardized incidence rate per 100 000 for week 13
British Columbia	125.2
Alberta	64.8
Saskatchewan	127.4
Manitoba	25.6
Ontario	126.3
Québec	75.1
Newfoundland and Labrador	N/A*
New Brunswick	N/A*
Nova Scotia	2.5
Prince Edward Island	3.8
Yukon	4.5
Northwest Territories	0.0
Nunavut	0.0
Canada	95.7**

Source: Detailed case information received by PHAC from provinces and territories, standardized to the July 1 2020 post-census population estimate.
*Age-standardized incidence could not be calculated as data was either not reported or partially reported to PHAC during week 13.
**The age-standardized incidence rate for Canada only includes provinces and territories for which data was available for week 13.
Note: Data are analyzed based on PHAC report date.

Table 3 outlines the total number of new cases, resolved cases, and deaths reported during week 13.

- Of the provinces and territories that reported new cases during week 13, all reported more new cases than new resolved cases.

Table 3. Summary of new COVID-19 cases, resolved cases, and deaths reported in Canada, and by province or territory, during week 13

Province/Territory	New cases	New resolved cases	New deaths
British Columbia	6 418	3 866	11
Alberta	5 663	2 210	14
Saskatchewan	1 540	1 208	6

DEMOGRAPHIC DISTRIBUTION[a]

[a] Detailed case information received by PHAC from provinces and territories
Note: Data are analyzed based on PHAC report date.

- Cases for which PHAC received detailed individual case-level information during week 13 (n=34 754) ranged in age from less than one year to 102 years of age. The median age was 34 years, no change from what was observed during week 12.
- Table 4 presents a summary of the age and gender distribution of COVID-19 cases reported to PHAC during week 13:
    - Fifty-nine percent (59%) were individuals under 40 years of age.
    - The highest proportions of cases by age group were observed among those aged 0-19 years (22%) and 20-29 years (20%).
    - The highest age specific incidence rates were observed among those 20-29 and 30-39 years of age.

Table 4. Age, gender distribution, and rate of COVID-19 cases reported to PHAC, during week 13

Age groups	Female			Male			Total[a]		
	n	%	Rate	n	%	Rate	n	%	Rate
≤ 19	3 945	22%	99.2	4 100	22%	98.5	8 045	22%	98.8
20-29	3 418	19%	138.6	3 644	20%	136.9	7 062	20%	137.7
30-39	2 893	16%	110.2	3 099	17%	116.2	5 992	17%	113.2
40-49	2 662	15%	108.7	2 659	14%	110.6	5 321	15%	109.6
50-59	2 289	13%	87.6	2 421	13%	93.7	4 710	13%	90.7
60-69	1 374	8%	56.9	1 538	8%	66.6	2 912	8%	61.6
70-79	679	4%	42.9	630	3%	44.2	1 309	4%	43.6

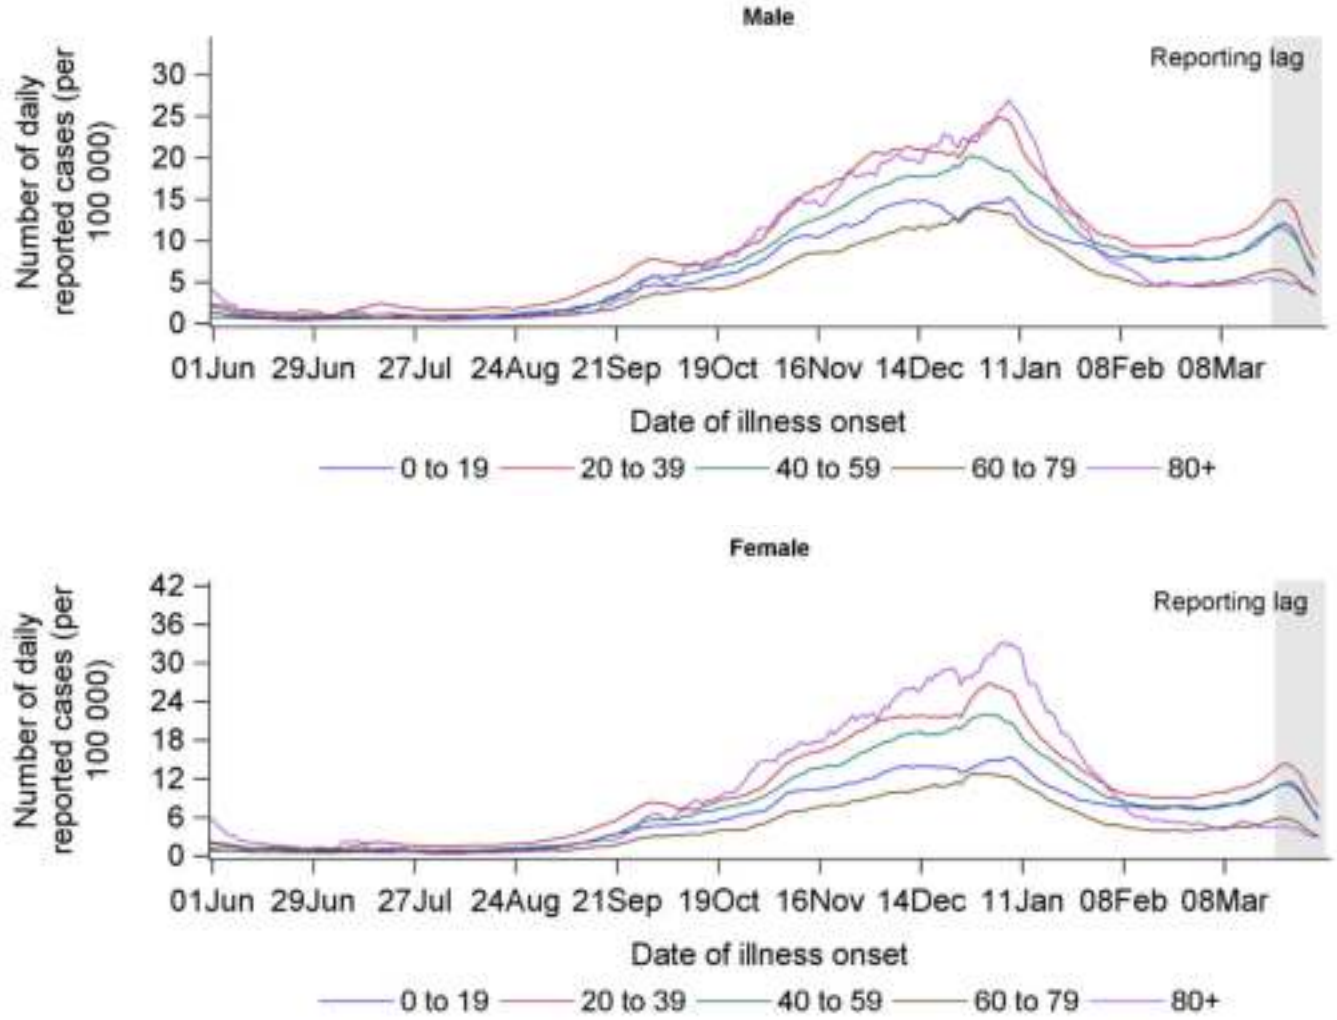
Total	17 656	100%	92.3	18 411	100%	97.5	36 067	100%	94.9

Source: Detailed case information received by PHAC from provinces and territories during week 13. Rates are presented per 100 000 individuals in the given age group based on the 1 July 2020 post-census population estimate.
[a] Cases not identified as male or female were removed from the total due to small numbers.
Note: Data are analyzed based on date reported to PHAC. Note that there is a period of time (lag time) where it is expected that cases have occurred but have not yet been reported nationally. Therefore, COVID-19 cases reported to PHAC during week 13 may include cases that occurred (based on date of illness onset, or lab related dates) in previous weeks.
Note: Cases with missing gender or age were excluded. Where available, gender data was used; when gender data was unavailable, sex data was used. Reliable data on gender diverse respondents are unavailable due to small counts.

Figure 2 presents cases by date of illness onset, stratified by gender and adjusted for population at the national level.

- Daily rates of cases have increased for most age groups in recent weeks; this follows the large decline observed since early January 2021.
- Daily rates of cases continue to remain highest among individuals in the 20 to 39 year age group for males and females. This age group has consistently been the highest since 20 January 2021 for males and 03 February 2021 for females.
- Daily rates of cases are lowest among individuals in the 80 years and older age group for both genders. The incidence rates for this age group are 1.9 times lower for males and 2.2 times lower for females compared to the 20 to 39 year age group.

Figure 2. Daily rate of cases per 100 000 population, by age and gender, from 1 June 2020 to 03 April 2021



Source: Detailed case information received by PHAC from provinces and territories. Rates are calculated based on the 1 July 2020 post-census population estimate.

Note: The shaded area represents a period of time (lag time) where it is expected that cases have occurred but have not yet been reported nationally. The earliest of the following dates were used as an estimate: Onset date, Specimen Collection Date, Laboratory Testing Date, Date Reported to Province or Territory, or Date Reported to PHAC.

Note: Where available, gender data was used; when gender data was unavailable, sex data was used. Reliable data on gender diverse respondents are unavailable due to small counts.

SYNDROMIC SURVEILLANCE

FLUWATCHERS

FluWatchers is an online health surveillance system that relies on volunteer reports to track the spread of Influenza-like illness (ILI) and symptoms compatible with COVID-19 across Canada. Some of the more commonly reported symptoms of COVID-19 include a new or worsening cough, fever or feeling feverish; therefore, reports of a minimum of cough or fever are being used to track COVID-19 within the FluWatchers system.

During week 13, 12 081 participants reported into the FluWatchers system. A total of 194 participants (1.6%) reported symptoms of cough or fever.

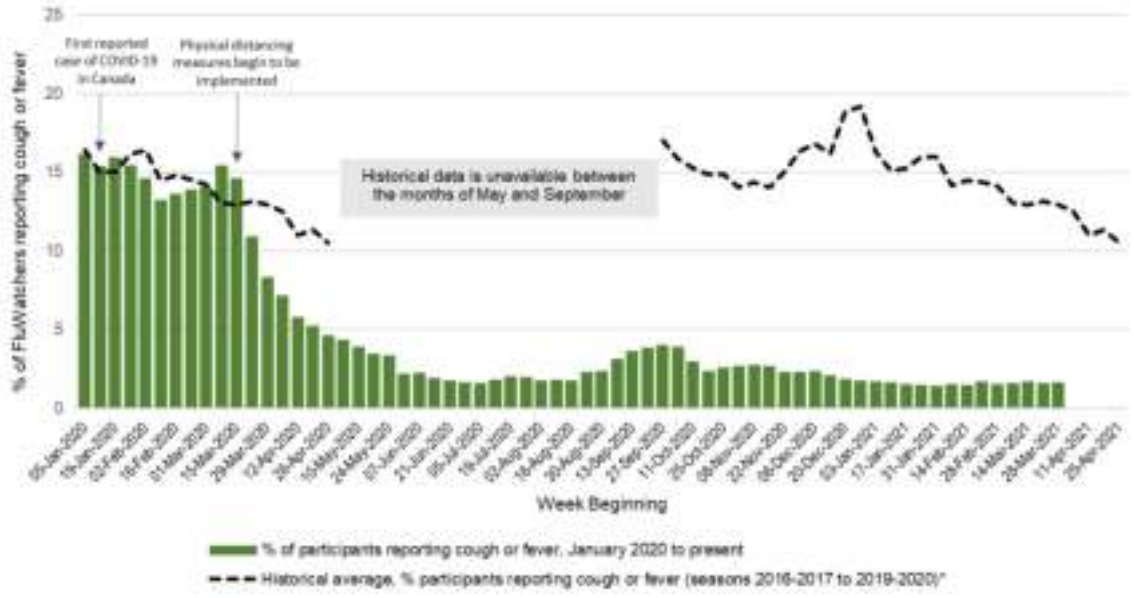
From mid-December 2020 to late-January 2021, FluWatchers activity was on a slow decline, despite increasing COVID-19 activity at the time. In recent weeks, activity due to seasonal respiratory viruses has been low and stable, COVID-19 activity has begun to increase and FluWatchers activity has slightly increased as well. Symptoms reports by FluWatchers participants remain below seasonal norms for this time of year.

Among the 194 participants reporting cough or fever:

- 88 (45%) sought medical attention;
- 76 (39%) were tested - 4 tests were positive for COVID-19 (8 tests had unknown results at the time of reporting)

Syndromic data captured by FluWatchers is sensitive to all circulating respiratory viruses, including COVID-19. The FluWatchers program is measuring total respiratory virus activity in the community. FluWatchers participants are a self-selected subset of the Canadian population that may not be representative of the Canadian population; thus, under representing the true measure of COVID activity in the population.

Figure 3. Percentage of FluWatchers Participants Reporting Cough or Fever (N=12 081 during week 13)



*Historical data is unavailable between the months of May and September. From January 2020 to May 2020, the historical epidemiological curve contains data from seasons 2016-2017 to 2018-2019. From October 2020 onwards, the historical epidemiological curve contains data from seasons 2016-2017 to 2019-2020; however, data from March 8, 2020 to May 2, 2020 are excluded from the historical epidemiological curve.

TRANSMISSION

TEMPORAL DISTRIBUTION BY EXPOSURE CATEGORY[a]

[a] Detailed case information received by PHAC from provinces and territories

During week 13, exposure and date of illness onset information was available for 20 329 cases. Of these:

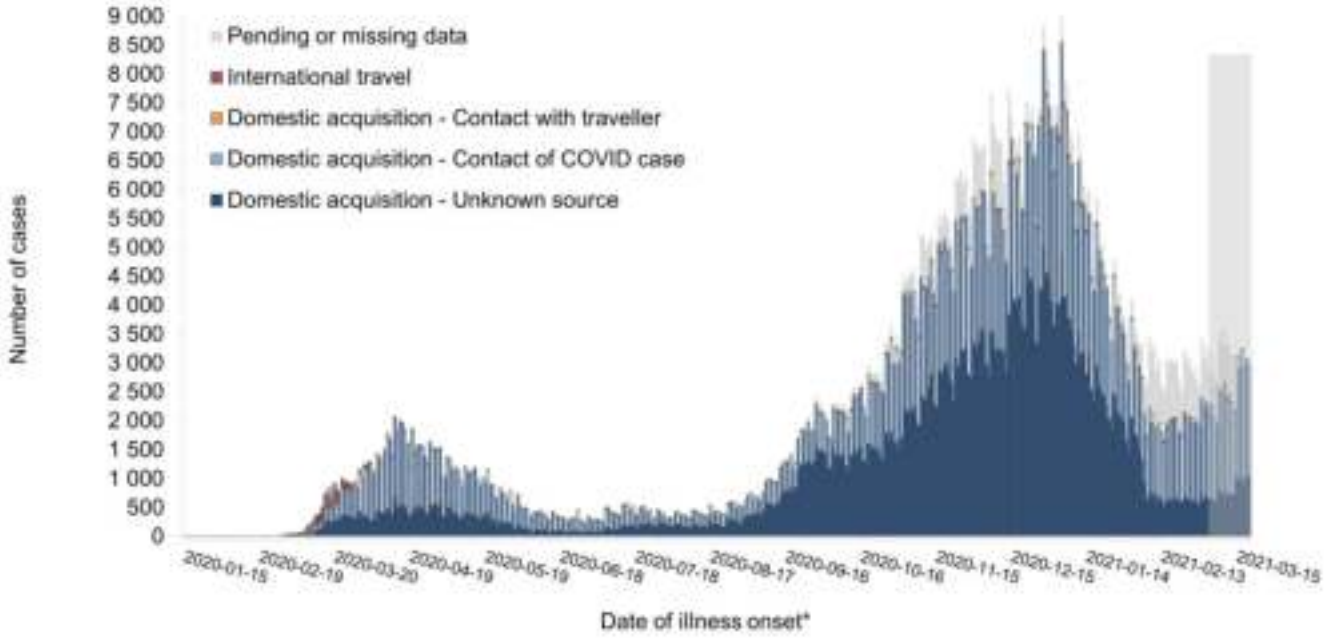
- 13 398 cases (66%) reported exposure in Canada to a known COVID-19 case;
- 6 820 cases (34%) reported exposure in Canada to an unknown source;
- 43 cases (<0.5%) reported exposure to a traveller; and
- 68 cases (<0.5%) reported having travelled outside of Canada during the exposure period.

Jurisdictions update exposure status on an ongoing basis as case investigations are completed and may result in changes to the percent distributions by exposure type for previous weeks (Figure 4).

Of the 883 392 cases submitted as of 03 April 2021 with information on the source of exposure and date of illness onset:

- 418 343 cases (47%) reported exposure in Canada to a known COVID-19 case;
- 449 898 cases (51%) reported exposure in Canada to an unknown source;
- 6 771 cases (1%) reported exposure to someone who had travelled; and
- 8 380 cases (1%) reported having travelled outside of Canada during the exposure period.

Figure 4. Number of reported COVID-19 cases in Canada, by date of illness onset and exposure category as of 03 April 2021 (n=991 533)



Source: Detailed case information received by PHAC from provinces and territories

* The earliest of the following dates were used as an estimate: Onset date, Specimen Collection Date, Laboratory Testing Date, Date Reported to Province or Territory, or Date Reported to PHAC.

Note: The shaded area represents a period of time (lag time) where it is expected that cases have occurred but have not yet been reported nationally. There is missing information for exposure variables from several provinces and territories.

INTERNATIONAL TRAVEL EXPOSURES[a]

[a] Detailed case information received by PHAC from provinces and territories

In Canada, the first cases of COVID-19 were attributed to international travel exposures. On 14 March 2020, the Government of Canada published a global Travel Health Notice advising Canadians against non-essential travel and advised Canadians abroad to return to Canada. By 21 March 2020, the Government of Canada prohibited all non-essential travel into Canada by foreign nationals. Since that time, the proportion of COVID-19 cases associated with international travel decreased from 22.3% (n=3 883) of all cases in March 2020 to 0.4% (n=127) in May 2020, and increased slightly over the summer months but has remained low since the fall (Table 5 and Figure 5). Since the spring of 2020, there have been significant efforts to enact border restrictions to reduce COVID-19 import to Canada.

As of 03 April 2021, 0.9% of cases with known exposure (n=8 380) have been associated with international travel. Since 01 July 2020, the United States, Mexico, and India are the top countries identified by cases that reported international travel during their exposure period.

Table 5. Number and percentage of COVID-19 cases associated with international travel by month of illness onset[a], as of 03 April 2021

Month	Number of COVID-19 cases associated with international travel	Percentage of COVID-19 cases associated with international travel[b]
January 2020	7	18.9%
February 2020	71	37.2%
March 2020	3 883	22.3%
April 2020	510	1.1%
May 2020	127	0.4%
June 2020	218	1.9%
July 2020	351	2.7%
August 2020	257	1.9%
September 2020	213	0.5%
October 2020	314	0.4%
November 2020	443	0.3%
December 2020	607	0.3%
January 2021	836	0.5%
February 2021	252	0.4%
March 2021	291	0.4%
Total	**8 380**	**0.9%**

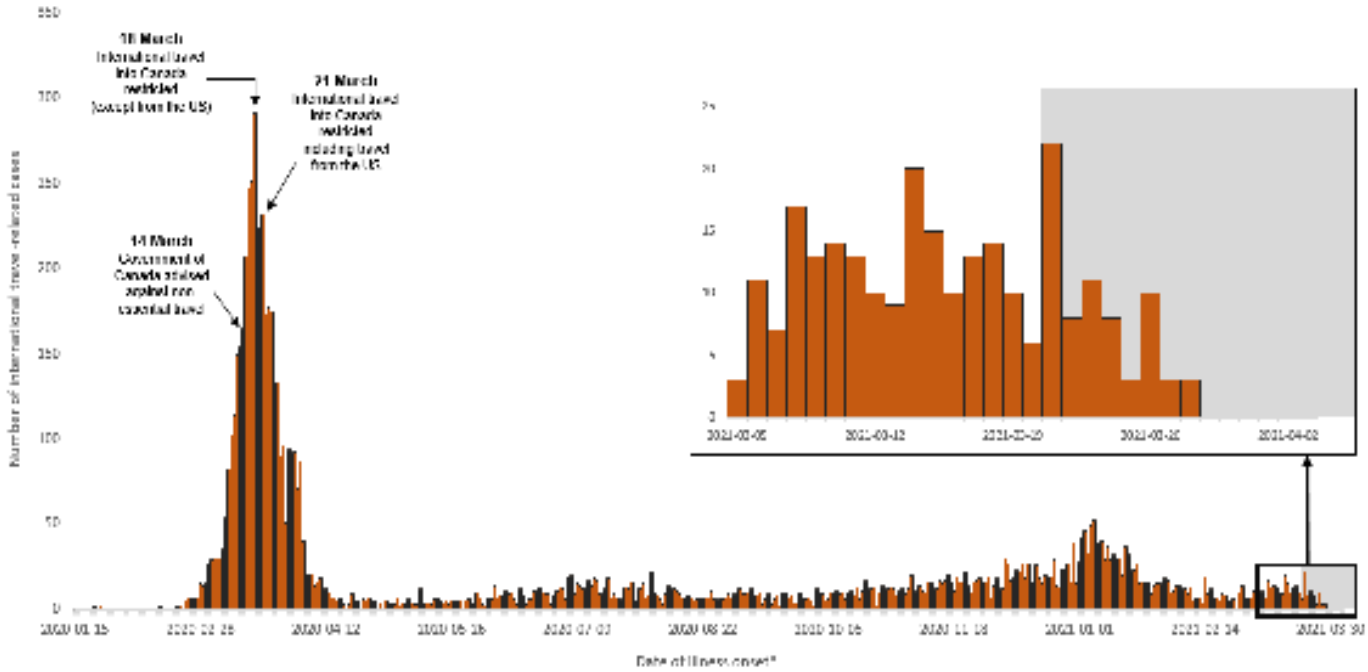
Source: Detailed case information received by PHAC from provinces and territories

Note: This is an underestimate of the total number of cases among returning travelers as exposure history are not available for all cases and not all jurisdictions have consistently reported exposure history to PHAC throughout the COVID-19 pandemic.

[a]The earliest of the following dates were used as an estimate: Onset Date, Specimen Collection Date, Laboratory Testing Date, Date Reported to Province or Territory, or Date Reported to PHAC.

[b]Only includes cases that have information on exposure.

Figure 5. Number of international travel-related COVID-19 cases in Canada, by date of illness onset[a] (n= 8 380) as of 03 April 2021



Source: Detailed case information received by PHAC from provinces and territories

* The earliest of the following dates were used as an estimate: Onset date, Specimen Collection Date, Laboratory Testing Date, Date Reported to Province or Territory, or Date Reported to PHAC.

Note: The shaded area represents a period of time (lag time) where it is expected that cases have occurred but have not yet been reported nationally.

Note: This is an underestimate of the total number of cases among returning travellers as exposure history are not available for all cases and not all jurisdictions have consistently reported exposure history to PHAC throughout the COVID-19 pandemic.

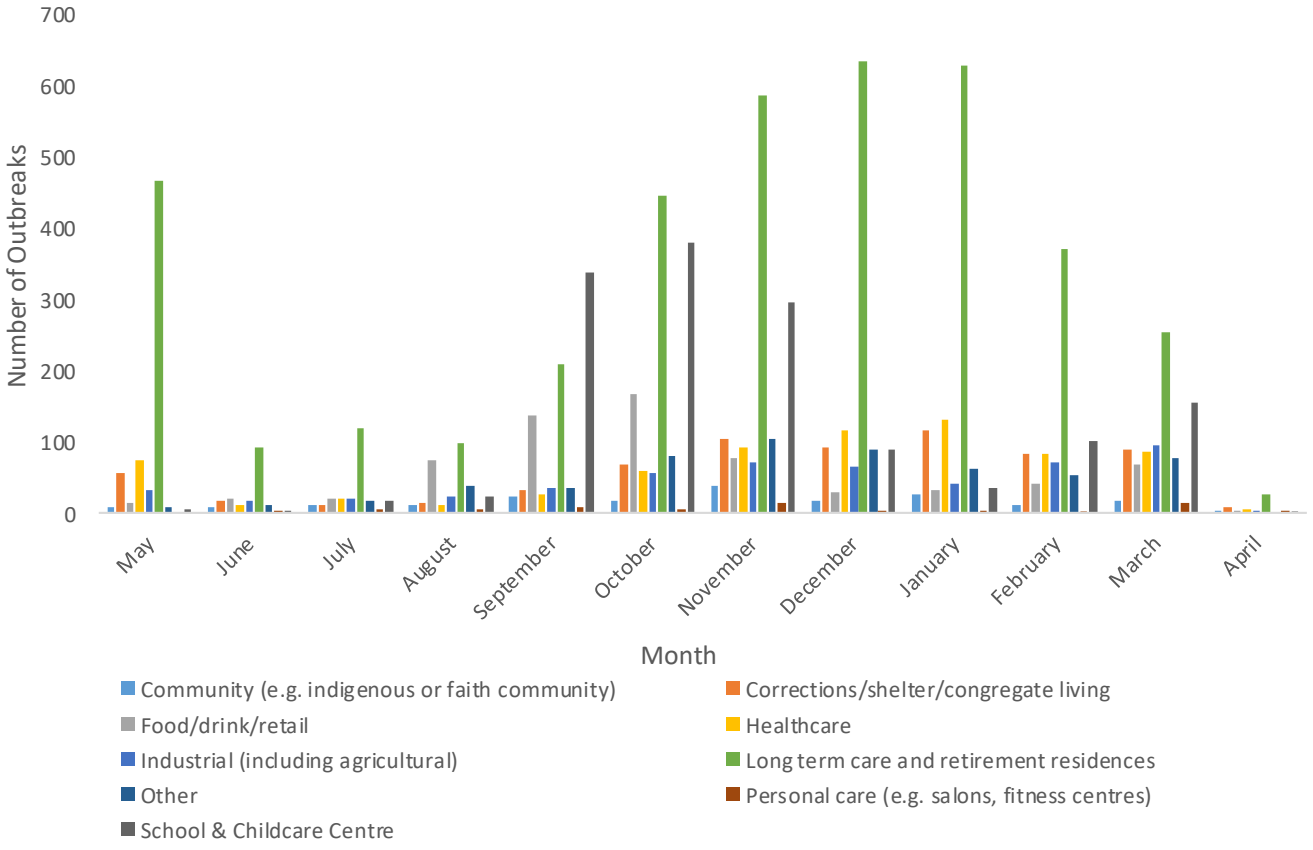
OUTBREAKS

Outbreaks have been a significant source of the spread of COVID-19 in Canada, and point to vulnerabilities in closed and crowded settings.

- Outbreaks have been detected in congregate living, workplace, and agricultural work settings, and namely in long-term care settings, meat processing plants, hospitals, small communities, and among farmworkers.
- Outbreaks continue to be observed in high-risk settings involving closed spaces, crowded places and close contact situations.
- Long-term care facilities and retirement residences continue to be the most commonly reported outbreak setting in Canada, and continue to account for the greatest proportion of outbreak related cases and deaths. This has been a consistent monthly trend with the exception of September, where reports of outbreaks in schools and childcare centres exceeded those in long-term care facilities and retirement residences.

Figure 6 and Table 6 identify common locations of outbreaks, as well as the number of cases and deaths associated with each.

Figure 6. Number of new outbreaks by setting as of 03 April 2021



Source: Publicly reported outbreak data, including Provincial and Territorial websites, as of 03 April 2021
Note: Schools with only one case, or those for which information on number of cases is unknown, have been excluded

Table 6. Total number of COVID-19 outbreaks, cases, and deaths by outbreak setting in Canada as of 03 April 2021[a]

Outbreak setting	Total number of outbreaks reported	Total number of cases reported	Total number of reported deaths	Outbreaks Reported in past 7 days
Community[b]	203	10 391	89	5
Corrections/shelter/congregate living	735	12 933	226	15
Food/drink/retail	685	2 489	3	20
Healthcare	765	10 648	812	18
Industrial (including agricultural)[c]	539	11 938	24	17
Long term care and retirement residences	4 430	66 863	12 473	61
Personal Care[d]	60	610	0	7
School & Childcare Centre[e]	1 438	8 199	1	31
Other[f]	585	5 331	6	17

Source: Publicly reported outbreak data, including Provincial and Territorial websites, as of 03 April 2021

[a]This is not an all-inclusive list and is subject to change based on current and active outbreak locations reported.

[b]Community includes population centres, Indigenous communities, Mennonite, Reserves, and small city outbreaks.

[c]The number of outbreaks in Windsor-Essex have been grouped into one cluster; industrial settings include: automotive manufacturing, distribution/processing facilities, worker camps, waste management/recycling, warehouse, etc.

[d]Personal care refers to personal care services, such as hair salons, nail salons, etc.

[e]Child and youth care include daycare centres and day camps; excludes any facilities that report only one case. Schools with only one case, or those for which information on number of cases is unknown, have been excluded

[f]Other groups together outbreaks in settings not listed in the categories above, for example social gatherings, office workplaces, recreational facilities, etc.

Note: These categories include both current and retrospective outbreak data.

LABORATORY-CONFIRMED COVID-19 DETECTION

During week 13, a total of 809 571 tests were performed, with an average of 115 653 tests performed daily for COVID-19 across Canada. The weekly percentage of tests positive during week 13 was 5.1%, an increase of 0.8% from the previous week (Table 7).

Table 7. Summary of COVID-19 tests performed in Canada, by province or territory, for week 13

Province/Territory	Cumulative number of tests performed as of 03 April 2021	Week 13 (28 March to 03 April, 2021)			
		Weekly number of tests performed	Average number of tests performed daily	Average # of tests performed daily per 1 000 population	Weekly percentage of tests positive[1]
British Columbia	2 222 958	61 093	8 728	1.7	10.4%

Canada	**28 278 760**	**809 571**	**115 653**	**3.04**	**5.1%**

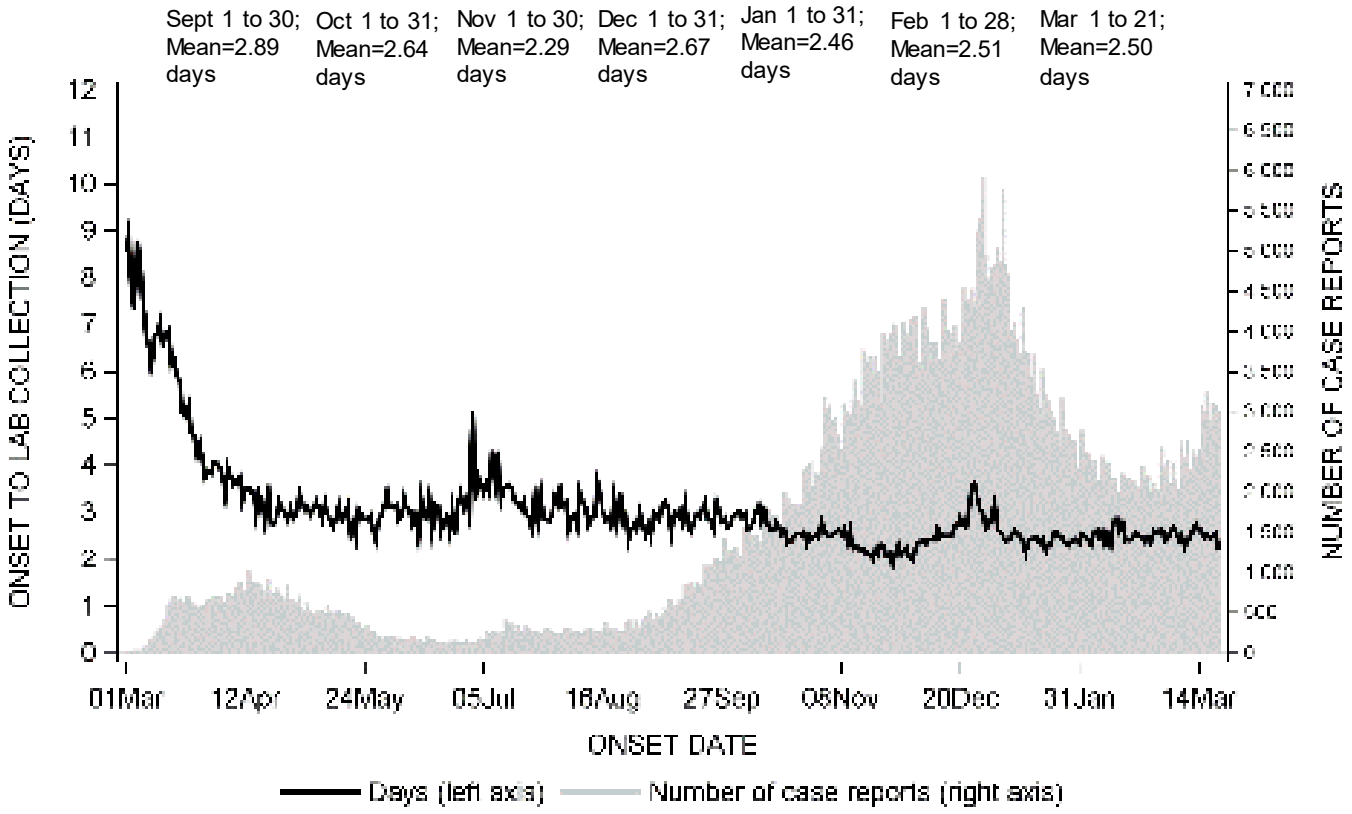
Source: NML Data for laboratory analyses as of 03 April 2021

[1] Weekly percentage of tests positive is calculated by dividing the total positive tests in the past 7 days by the total tests performed in the past 7 days

Note: Laboratory testing numbers may be an underestimate due to reporting delays and may not include additional sentinel surveillance or other testing conducted in the province or territory.

The mean time from symptom onset to lab specimen collection was 2.50 days in March 2021. This is similar to the mean of 2.51 days in February 2021 (Figure 7).

Figure 7. Onset date to laboratory collection date for cases reported to PHAC as of 03 April 2021



Source: Detailed case information received by PHAC from provinces and territories
Note: Date of symptom onset to date of specimen collection intervals of >15 days are deemed outliers, and not included in this figure.

SEVERITY INDICATORS

HOSPITALIZATIONS, INTENSIVE CARE, AND DEATHS

During week 13, detailed case information on hospitalization status was available for 18 578 cases. Among these cases:

- **700 (4%)** were hospitalized (including ICU admission), of whom:
  - **87 (12%)** were admitted to ICU.

Among the total number of hospitalizations reported during week 13 for which age information was available, 24% (n=166/695) were 40 to 59 years of age, 41% (n=287/695) were 60 to 79 years of age, and 21% (n=143/695) were 80 years and older (Table 8).

As of 03 April 2021, case information on hospitalization status was available for 694 621 cases, where:

- **52 835 (8%)** were hospitalized (including ICU admission), of whom:
  - **9 337 (18%)** were admitted to ICU.

Since the beginning of the pandemic, the 60 to 79 year age group has accounted for the highest proportion of cases hospitalized and admitted to ICU, followed closely by the 80 years and older age group (see table A5 in annex for cumulative counts).

Table 8. Number of COVID-19 cases hospitalized, and admitted to ICU, overall and by gender and age group, reported to PHAC during week 13[a]

Age groups	Hospitalized – non-ICU			Hospitalized – ICU		
	Female	Male	Total	Female	Male	Total
≤ 19	11	10	21	0	1	1
20-39	30	39	69	2	6	8
40-59	66	82	148	8	10	18
60-79	107	136	243	16	28	44
80+	61	66	127	9	7	16
Total	275	333	608	35	52	87

Source: Detailed case information received by PHAC from provinces and territories

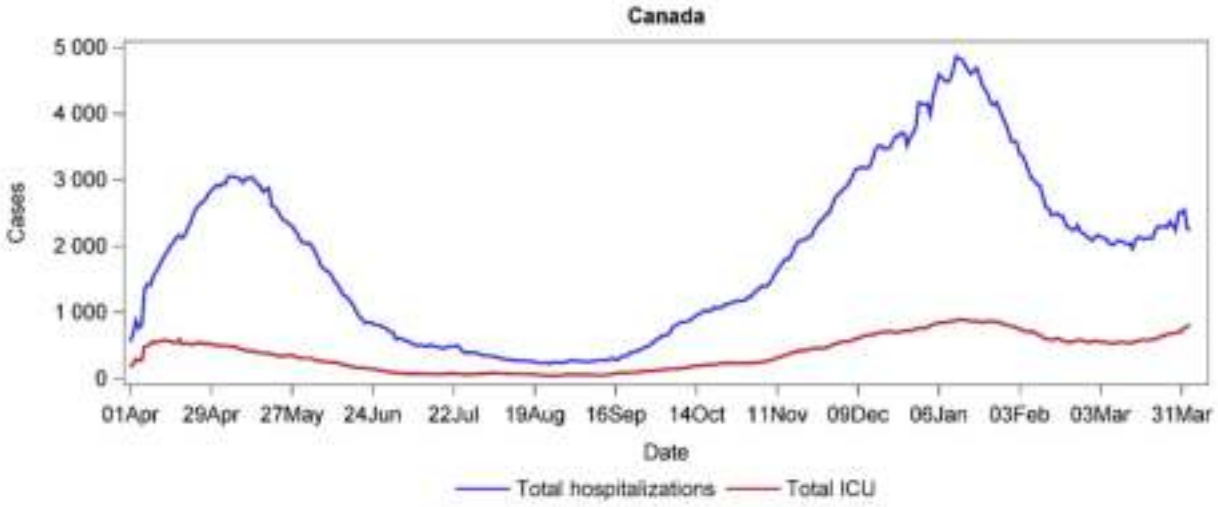
[a] Data are analyzed based on date reported to PHAC. Note that there is a period of time (lag time) where it is expected that cases have occurred but have not yet been reported nationally. Therefore, COVID-19 cases reported to PHAC during week 13 may include cases that occurred (based on date of illness onset, or lab related dates) in previous weeks.

Note: Non-ICU hospitalizations and ICU counts are mutually exclusive. Cases with missing gender, sex or age were excluded. Where available, gender data were used; when gender data were unavailable, sex data were used. Reliable data on gender diverse respondents are unavailable due to small counts.

Following a sharp decline in hospitalizations, and stabilized numbers of ICU admissions since early January 2021, the number of hospitalizations and ICU admissions have begun to increase (Figure 8). On 03 April 2021, there were 2 250 cases hospitalized and 801 cases in ICU, representing a 5% increase in the seven-day moving average of hospitalized cases and a 16% increase in the seven-day moving average of ICU admissions compared to one week prior.

Based on detailed case information received by PHAC from provinces and territories, the overall cumulative hospitalization rate (including ICU admissions) is 139 cases per 100 000 population, with the highest rates observed among those aged 80 years and older (1 013 cases per 100 000 population).

Figure 8. Number of COVID-19 cases in hospital and ICU daily in Canada, as of 03 April 2021



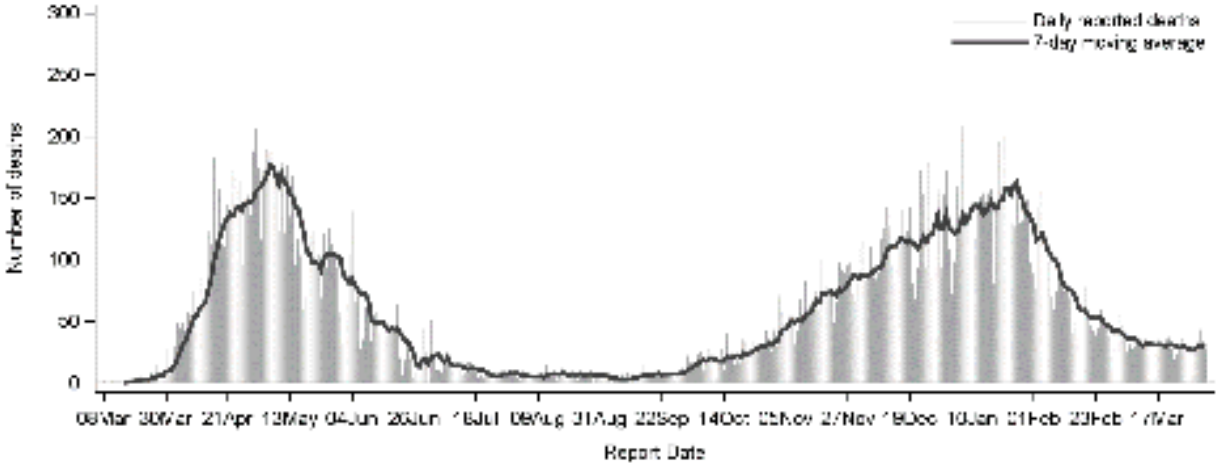
Source: Provincial and Territorial MOH websites as of 03 April 2021

During week 13, there were 195 COVID-19 related deaths reported in Canada.

- This represents an 8% decrease compared to the previous week.
- This amounts to an average of 28 deaths reported per day, compared to an average of 30 deaths per day during the previous week.
- There has been an overall decreasing trend in the number of deaths observed since late January 2021 (Figure 9).

Of the deaths reported during week 13, jurisdictions submitted case-level information to PHAC for 27 deaths, of which 18 (67%) were male and 96% were aged 60 years and older. To date, deaths are highest among those aged 80 years and older (Table A4 in the annex, cumulative counts).

Figure 9. Daily number of COVID-19 related deaths reported in Canada (and 7-day moving average), as of 03 April 2021 (N=23 050)



Source: Provincial and Territorial MOH websites as of 03 April 2021

Note: The 7-day moving average is a trend indicator that captures the arithmetic mean of the daily reported deaths over the previous seven days. The moving average helps smooth out day-to-day variability in reporting, filtering out the "noise" of short-term fluctuations. Fluctuations can be attributed to retrospective data or provinces or territories reporting cases at a reduced frequency.

CANADIAN ACUTE CARE HOSPITALS

Laboratory-confirmed COVID-19-associated hospitalizations in Canada are monitored through two sentinel hospital-based systems:

1. Canadian Nosocomial Infection Surveillance Program (CNISP) *
2. Serious Outcomes Surveillance Network of the Canadian Immunization Research Network (CIRN-SOS) **

NOTE: * denotes data from CNISP and ** data from CIRN-SOS

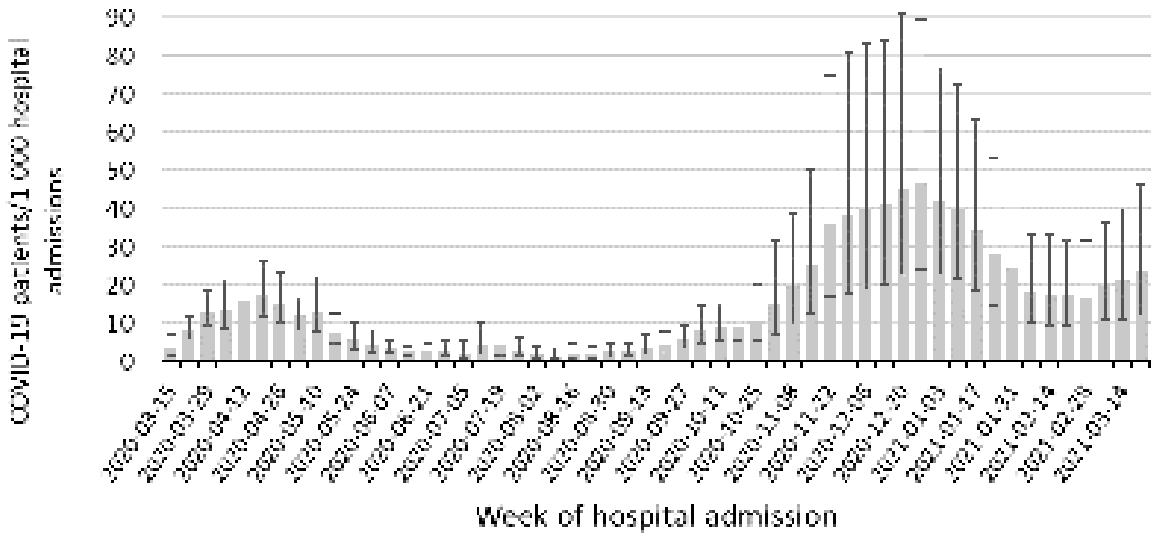
Key Findings*

- Among all patients hospitalized with COVID-19 since March 2020:
  - 20% have been admitted to the ICU (3 082/15 731)
  - 12% required mechanical ventilation (1 931/15 731)
  - <1% received extracorporeal membrane oxygenation (ECMO) (141/15 731)
  - 15% have died (all-cause mortality) (2 356/15 731)
- The median age of patients hospitalized with COVID-19 was 68 years (range 0-104 and 4% are pediatric (<18 years) (554/15 731)
- Males accounted for 54% of hospitalized patients (2 185/4 063)

Hospitalization Rates

- The weekly rate of new laboratory-confirmed COVID-19 patients per 1 000 hospital admissions was 23.8 for the most recent week of 21 March 2021 (Figure 10). The weekly incidence rate of hospitalizations has increased each week since the week of 28 February 2021 (Figure 10).

Figure 10. National rates of laboratory-confirmed COVID-19 patients per 1 000 admissions with 95% confidence intervals (n=15 731)*



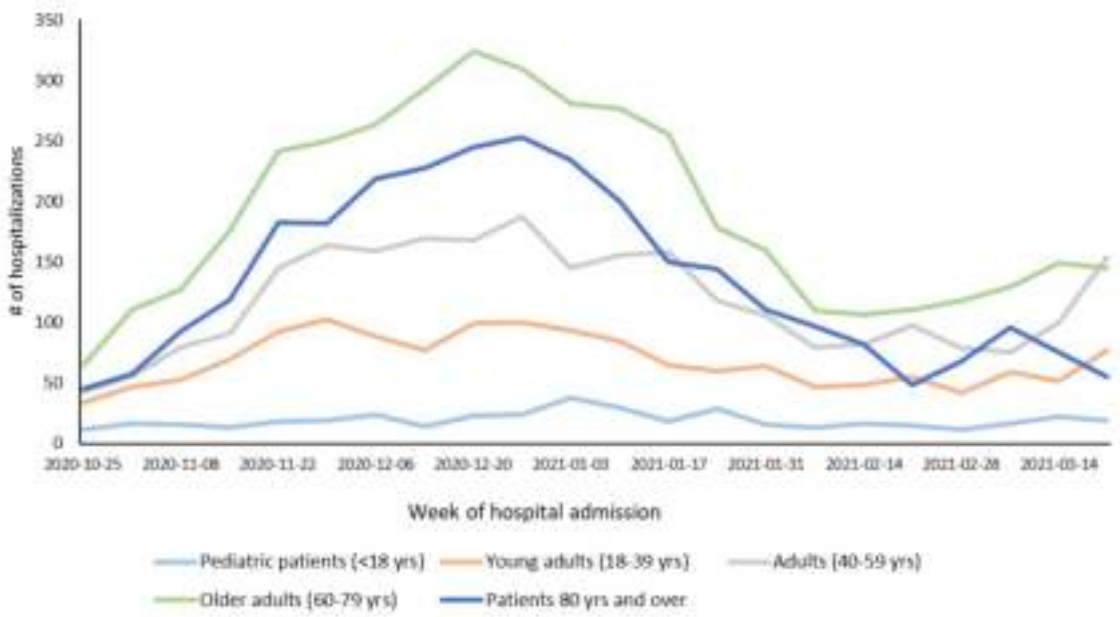
[a] Includes data from the 151 hospitals that have participated in all weeks of aggregate data collection. Denominator data are estimated using 2020 annual patient admissions.*

Hospitalization Trends

AGE *

- There was an increase observed in the number of hospitalizations among young adults (18-39 years) and adults (40-59 years) in the most recent week of 21 March 2021, with adults (40-59 years) accounting for the greatest number of hospitalizations for that week (Figure 11).
- Hospitalizations among patients 80 years and over have continued to decrease since the week of 07 March 2021 (Figure 11).
- Hospitalizations among pediatric patients (<18 years) have fluctuated, but consistently remained low (Figure 11).

Figure 11. Weekly number of new laboratory-confirmed COVID-19 patients by age group (n=11 728)*



CLINICAL PROGRESSION **

Time from symptom onset to hospital admission:

- Median length of time from symptom onset to hospital admission was shortest at 3 days among patients aged 80+ years (n=745), compared to 4 days among patients aged 16-39 years (n=162), 5 days among patients aged 60-79 years (n=852) and 6 days among patients aged 40-59 years (n=417).

Length of hospital stay:

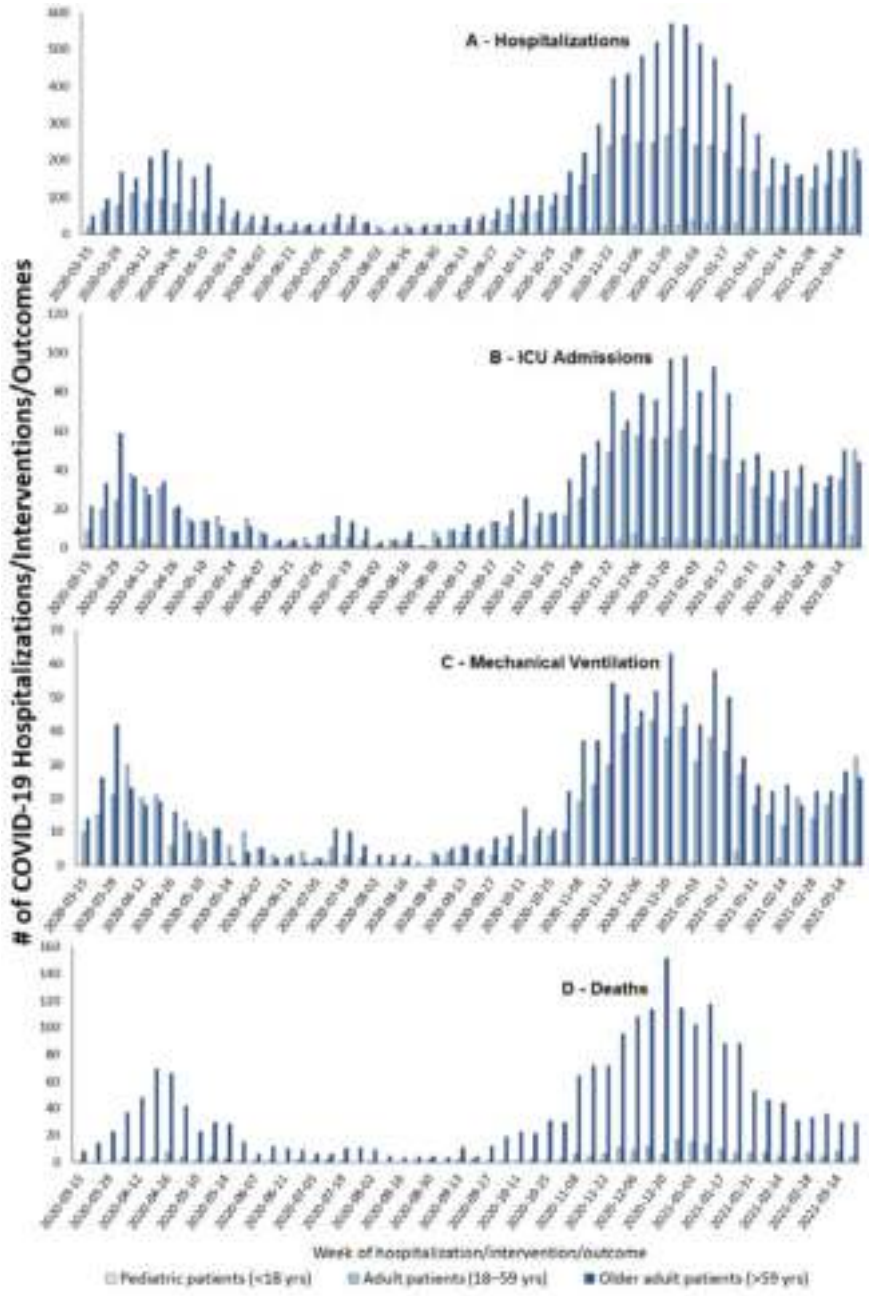
- Median length of hospital stay was longest among patients aged 80+ years (median=12 days, n=658) and patients aged 60-79 years (median=11 days, n=738). Values were comparatively lower for patients aged 40-59 years (median=6 days, n=352) and 16-39 years (median=4 days, n=134).

Note: Patients hospitalized before symptom onset were excluded from 'time from symptom onset to hospital admission' calculations. Length of stay is calculated as the time (in days) between date of hospital admission and date of outcome (including discharge, transfer, status change to alternate level of care, and death).

INTERVENTIONS/OUTCOMES *

- The number of new weekly hospitalizations, ICU admissions, and patients receiving mechanical ventilation have each increased since the week of 28 February 2021. Note that the increase observed in the most recent week of 21 March 2021 was largely driven by adult patients (18-59 years), as these measures all decreased among older adult patients (>59 years) (Figure 12).
- The number of deaths have remained relatively stable in recent weeks (Figure 12).

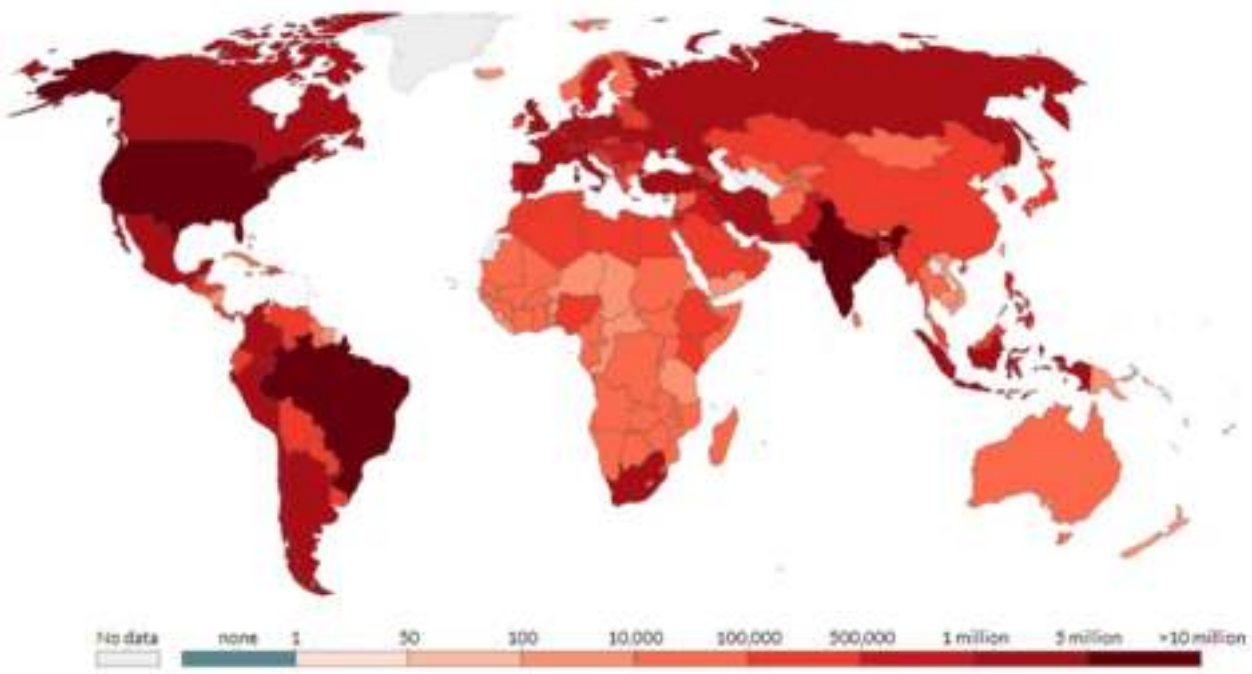
Figure 12. Weekly number of new laboratory-confirmed COVID-19 patients that were admitted to hospital (A; n=15 731), ICU (B; n=3 082), required mechanical ventilation (C; n=1 931), and deceased (D; n=2 356), by age group*



INTERNATIONAL

- As of 03 April 2021, there are over 129 million global cases of COVID-19 with over 2.8 million reported deaths (Figure 13).
- The region of Europe accounts for the highest number of cases reported.
- The following five countries account for the largest proportion of cases reported globally in the past 14 days:
    - Brazil (n=1 003 138)
    - India (n=886 379)
    - United States (n=885 934)
    - France (n=490 035)
    - Turkey (n=452 358)
- Canada's cases account for approximately 0.8% of all cases reported globally since the beginning of the pandemic.

Figure 13. International map of COVID-19 cases as of 03 April 2021 (n=129 943 007)

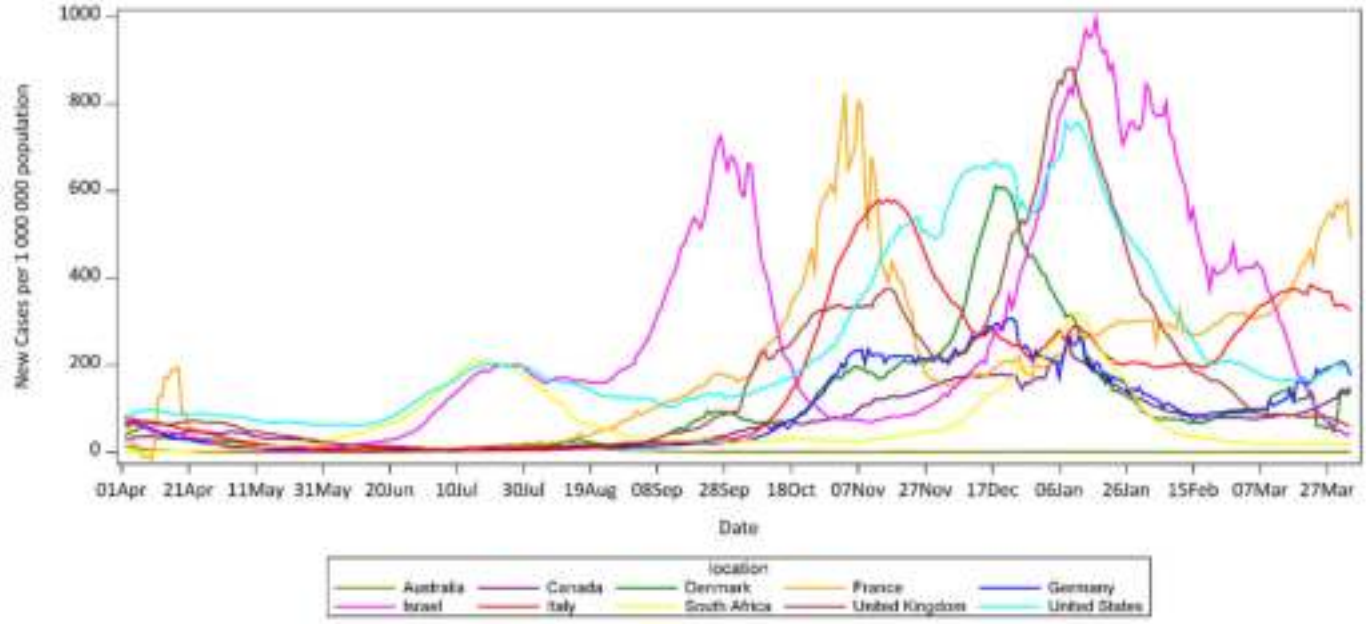


Source: Our World in Data – Coronavirus Pandemic (COVID-19) - https://ourworldindata.org/coronavirus

France continues to experience the highest rates of new cases compared to other countries, with 489.2 new cases per 100 000 population on 03 April 2021. Italy and the United States are second and third highest, with 325.6 and 195.2 new cases per 100 000 population, respectively.

Daily rates of cases in Canada are steadily increasing with 149.2 cases per 100 000 population on 03 April 2021. The rates of new cases in Canada are 3.3 times lower than France, 2.2 times lower than Italy, and 1.2 times lower than the United States.

Figure 14. Weekly new cases of COVID-19 in Canada compared to other countries as of 03 April 2021 (7-day moving average, population-adjusted)



Source: OurWorldInData, as of 03 April 2021

Up-to-date country-specific risk levels are found on travel health notices. For more information on COVID-19 internationally, please refer to the World Health Organization's COVID-19 Situation Report.

MODELLING

Estimates of transmission rates in Canada: Effective reproductive rate (*Rt*)

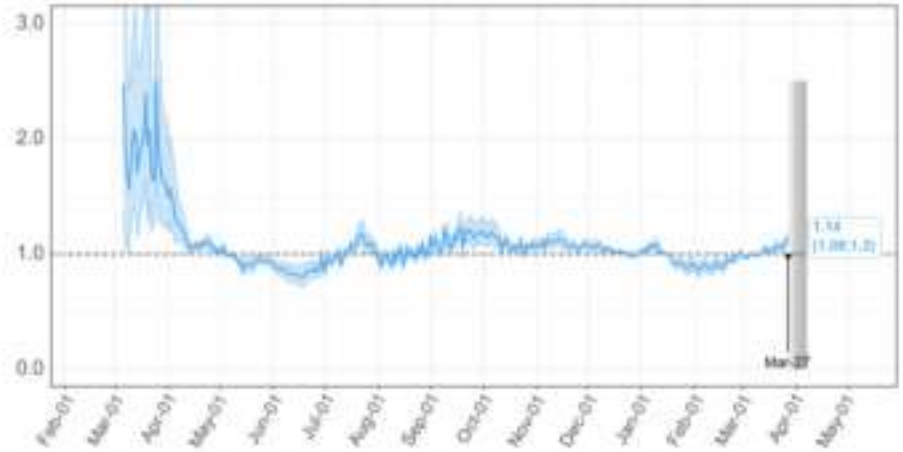
Rt is the time variable reproduction rate, representing the average number of newly infected people for each infected person. If Rt is less than 1 at a particular time (t), than the average number of people infected by one infected person is less than one, so the epidemic is being brought under control. If Rt is greater than 1, the average number of people infected by one infected person is greater than one, and the epidemic is growing. A value of Rt above 1 indicates that there is active community transmission, meaning that the disease will continue to spread in the population. The higher the Rt value, the faster the disease is spreading, which leads to an increase in the incidence of new cases.

However, there are some limitations to consider. As the epidemic continues, the Rt may not capture the current state of the epidemic with low case burden and the value must be interpreted based on the current landscape. The Rt can easily fluctuate when case numbers are low. It is also an average Rt for a population and does not point to local outbreaks driving case counts. Since the method used to calculate Rt is highly sensitive to the reported number of new cases, community outbreaks within specific provinces and territories will cause the estimated Rt value in that respective region to be higher, which may not always accurately depict overall transmission in the province or territory as a whole.

Figure 15 shows the Rt over time.

- In 2020, the reproductive rate was hovering under 1 in May and early June, followed by fluctuations in July. In early August, the Rt increased until the end of September when it decreased to just above 1. Between October 2020 and January 2021, the Rt fluctuated just above 1 with a slight increase in early November and early January. Starting in mid-January 2021, the Rt decreased to below 1, indicating that the epidemic was reducing nationally.
- Since early February 2021, the Rt has begun to slowly increase. The national Rt was 1.14 on 27 March 2021, an increase from 1.07 during the previous week.

Figure 15. Reproductive rate in Canada based on date of case report



Source: Calculated from detailed case information received by PHAC from provinces and territories
Note: Fluctuations are attributed to provincial and territorial reporting delays and non-reporting on the weekends

FORECASTING

Canada's approach to modelling:

Models cannot predict the course of the COVID-19 pandemic, but can help us understand all possible scenarios, support decisions on public health measures and help the health care sector plan for these scenarios.

Forecasting models use data to estimate how many new cases can be expected in the coming weeks. Figure 16 below shows the projected number of cases and deaths in Canada, with a 95% prediction interval calculated to 18 April 2021, using available data as of 03 April 2021.

- According to forecasting, between 1 093 510 to 1 150 910 cumulative reported cases and 23 290 to 23 710 cumulative reported deaths are expected by 18 April 2021.
- The black dots represent actual data (cumulative cases and cumulative deaths) prior to 03 April 2021 and the dashed lines show the predicted trajectories after that date.
- It is important to communicate uncertainties in the predictions. The red and green lines represent the upper and lower limits with 95% confidence, respectively.
- If the added data points since 03 April 2021 stay between the red and green lines, it means both (i) the prediction model is performing as expected; (ii) data generated by the epidemic and reporting mechanisms are as expected.
- If the added data points since 03 April 2021 fall outside these limits, especially above the red line, the model detects unexpected signals that require further epidemiologic investigation.

Figure 16. Projected numbers to 18 April 2021 and 95% prediction intervals based on data reported as of 03 April 2021

TECHNICAL NOTES

The data in the report are based on information from various sources described below. The information presented for case-based analyses, trend analyses and laboratory analyses are available as of **03 April 2021 at 4 p.m. EDT.**

DATA SOURCES AND DATA CAVEATS

Epidemiological data received by PHAC

Some of the epidemiological data for this report are based on detailed case information received by PHAC from provinces/territories (P/Ts). This information is housed in the PHAC COVID-19 database. Case counts and level of detail in case information submitted to PHAC varies by P/T due to:

- Possible reporting delay between time of case notification to the P/T public health authority and when detailed information is sent/received by PHAC.
- Preliminary data may be limited and data are not complete for all variables.
- Data on cases are updated on an ongoing basis after being received by PHAC and are subject to change.
- Variation in approaches to testing and testing criteria over time within and between P/Ts.
- The lag time from illness onset to PHAC report date is approximately two weeks and data within this period is subject to change.

Note: Missing data for hospitalizations, ICU admissions, and deceased were not included in calculations. Unless calculations were broken down by age and gender, cases with missing values for age and gender were included. P/Ts may define gender differently and some may be referring to biological sex. Case severity is likely underestimated due to underreporting of related variables, as well as events th at may have occurred after the completion of public health reporting, and therefore is not captured in the case report forms. Transmission data should be interpreted with caution as information on exposure are missing from several provinces and territories.

Provincial and territorial case counts

P/T information on case counts, resolved cases, and deaths associated with COVID-19 are collected from publicly available P/T websites, generally from the P/T ministry of health. Case definitions may vary by P/T.

- National COVID-19 case definitions are provided by PHAC for the purpose of standardized case classification and reporting. PHAC's national case definitions can be found here: https://www.canada.ca/en/public-health/services/diseases/2019-novel-coronavirus-infection/health-professionals/national-case-definition.html
- Only cases and deaths meeting P/T's definition for case classification are reported. For details on case definitions, please consult each P/T ministry of health website.

Laboratory information

Data on the number of tests conducted in each P/T are received from the National Microbiology Laboratory.

- Laboratory testing numbers may be an underestimate due to reporting delays and may not include additional sentinel surveillance or other testing performed. They are subject to changes as updates are received.

Outbreak data

Reporting delays and gaps in information that are available at the federal level present difficulties in reporting on local outbreaks. To ensure timely information is available, PHAC utilizes web-scraping techniques to gather outbreak data from media and P/T public health agency websites. There are several important limitations to these data:

- A nationally standardized outbreak definition does not yet exist. Cluster definitions vary according to P/T. The methods for defining an outbreak are currently in development and may change over time.
- The data do not represent all outbreaks that have occurred in Canada over the course of the pandemic, but they do provide a summary of clusters reported via non-traditional data sources. Data collection on outbreaks began 12 March 2020.
- Case-level data are generally not available for outbreaks detected via non-traditional data sources. Information presented is at the aggregate level only.

Population data

- Canadian population data from Statistics Canada Population estimates on 1 July 2020 are used for age-standardized and age-specific rate calculations.

International data

International data are retrieved from the European Centre for Disease Prevention and Control (ECDC) Situation update and Our World in Data.

- Given that the pandemic is rapidly evolving and the reporting cycles from government sources are different, the case numbers may not necessarily match what is being reported publicly. Rather, this reflects what is publicly available from the sources listed above.
- International comparisons should be interpreted with caution. Number of tests conducted, indications for testing, and diagnostic capacity by country have a large influence on total number of reported cases. Therefore, the data displayed may not represent the true incidence of disease within each country.

Canadian Acute-Care Hospitalization Data

Canadian Nosocomial Infection Surveillance Program (CNISP) collects information on hospitalized patients across all age groups (pediatric and adult).

- As of 27 March 2021, CNISP has collected weekly aggregate data on 15 731 adult and pediatric patients hospitalized with COVID-19 from 151 hospitals across all 10 provinces and 1 territory.
- CNISP has conducted surveillance among 56 hospitals across 10 provinces and 1 territory and as of 12 March 2021 has collected case-level data on 4 063 adult and pediatric patients hospitalized with COVID-19

Serious Outcomes Surveillance Network of the Canadian Immunization Research Network (CIRN-SOS) collects information on hospitalized adult patients aged 16 years or older.

- As of 1 April 2021, CIRN-SOS has collected case-level data on 2 950 adult patients (≥16 years) hospitalized with COVID-19 across 9 hospital sites in Alberta, Ontario, Québec, and Nova Scotia.
- Denominators may be lower depending on variable completeness.

*** denotes data from CNISP and ** data from CIRN-SOS**

ANNEX

Table A1. Cumulative number of COVID-19 cases, resolved cases, and deaths reported in Canada by province or territory, as of 03 April 2021

Province/Territory	Total cases	Total resolved cases	Total deaths
British Columbia	103 031	91 732	1 463
Alberta	151 359	138 560	1 994

Abstract

It is essential to understand where and how severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is transmitted. Case reports were extracted from the local Municipal Health Commissions of 320 prefectural municipalities in China (not including Hubei Province). We identified all outbreaks involving three or more cases and reviewed the major characteristics of the enclosed spaces in which the outbreaks were reported and their associated indoor environmental aspects. Three hundred and eighteen outbreaks with three or more cases were identified, comprising a total of 1245 confirmed cases in 120 prefectural cities. Among the identified outbreaks, 53.8% involved three cases, 26.4% involved four cases, and only 1.6% involved ten or more cases. Home-based outbreaks were the dominant category (254 of 318 outbreaks; 79.9%), followed by transport-based outbreaks (108; 34.0%), and many outbreaks occurred in more than one category of venue. All identified outbreaks of three or more cases occurred in indoor environments, which confirm that sharing indoor spaces with one or more infected persons is a major SARS-CoV-2 infection risk.

KEYWORDS

COVID-19, crowding, indoor environments, indoor hygiene, outbreak, SARS-CoV-2

1 | INTRODUCTION

In less than 4 months, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) spreads rapidly to all countries worldwide. By the end of June 2020, it had infected more than 10 million people and, by developing into coronavirus disease 2019 (COVID-19), had caused or contributed to the deaths of half a million people.[1] Understanding where and how person-to-person SARS-CoV-2 transmission occurs is essential for effective intervention.

The once-in-a-century COVID-19 pandemic has occurred in the age of artificial intelligence and big data. Many clusters/outbreaks were identified via contact tracing by local health authorities in China and elsewhere using both traditional and new technologies. The identification of these clusters allowed health authorities to quarantine close contacts for effective intervention and provided an opportunity to study the characteristics of where and how these clusters occurred. The first COVID-19 patient was identified in Wuhan in December 2019, and the largest number of confirmed Chinese cases occurred in Hubei Province, of which Wuhan is the provincial capital.[2] Since January 20, 2020, the local health authorities of cities outside Hubei have reported online the details of most identified cases of infection. These were nearly only cases of SARS-CoV-2 infection that had progressed to actual disease (ie, COVID-19) and necessitated hospitalization, as by February 11, 2020, our knowledge of asymptomatic infection was non-existent.

In this study, we identified the outbreaks from these case reports from the local Municipal Health Commissions of 320 prefectural cities (municipalities) in China, not including Hubei Province, between January 4 and February 11, 2020. We also reviewed the major characteristics of the enclosed areas in which these outbreaks

Hua Qian, Te Miao and Yuguo Li contributed equally.

© 2020 John Wiley & Sons A/S. Published by John Wiley & Sons Ltd

were determined to have occurred and their associated indoor environmental aspects.

2 | METHODS

We collected descriptions of each confirmed case from the local Municipal Health Commission website of 320 prefectural cities in mainland China, not including Hubei province. Each local Municipal Health Commission gave daily descriptions of the confirmed cases. The case descriptions generally included age, sex, venue of infection, symptoms, date of symptom onset, hospitalization, and confirmation and history of exposure. Many described cases also included patient's trajectory and relationship with other confirmed cases, and clusters had often already been identified. We consulted nationwide websites, except for those of cities in Hubei Province, and collected all available data up to February 11, 2020. Data from a few major cities—Beijing, Shanghai, and Guangzhou—were not included in our analysis due to insufficient case descriptions. Case descriptions from Hong Kong, Macao, and Taiwan were collected from their respective health authorities. We input the data into a database and conducted cross-validation to insure data reliability.

A total of 7324 cases with the minimum required descriptions (ie, the information listed above) were found; these accounted for 66.7% of the 10 980 confirmed non-Hubei cases in China by February 11, 2020.[3] In this study, we defined a *cluster* as an aggregation of *three* or more cases that appeared to be linked to the same infection venue (eg, an apartment, an office, a school or a train) during a period in which people were insufficiently close proximity. We defined an *outbreak* as a cluster in which a common index patient was suspected, and we excluded tertiary and higher-generation infections in counting the number of cases involved. We also excluded outbreaks that involved only two cases, to exclude possible spouse-to-spouse transmission and to reduce the workload due to the large number of clusters or outbreaks with two cases. We also identified the index patient(s) of the identified outbreaks and their date of symptom onset.

We divided the identified outbreaks into categories for further analysis. First, the following six categories of infection venues were considered: homes (apartments and villas), transport (eg, normal and high-speed trains, private cars, buses, passenger planes, taxis, and cruise ships), restaurants and other food venues, entertainment venues (gyms, mah-jong halls, card houses, tea houses, and barbershops), and shopping venues (shopping malls and supermarkets), and an additional miscellaneous category (eg, hospitals, hotel rooms, unspecified communities, and thermal power plants). Second, the following four categories of infected individuals were considered based on their relationship: family members, family relatives, socially connected individuals, and socially non-connected individuals. A socially connected relationship was defined as one that existed between individuals who had possibly been in close contact due to friendships, acquaintances, or jobs, but did not include family connections (family members or relatives). A socially non-connected relationship was defined as one with no social connection or family connection.

Practical Implication

- The indoor environments in which we live and work are the most common venues in which SARS-CoV-2 is transmitted.
- There is a need to improve the hygienic and ventilation conditions of these indoor environments to decrease the transmission of airborne infectious diseases.
- Given that there is an association between crowding and infection, in the post-pandemic future, we need to reflect deeply on the need for a healthy indoor environment.

3 | RESULTS

We identified 318 outbreaks involving 1,245 infected individuals in 120 cities. The top three cities (Table S2) were Shenzhen, Guangdong (24 outbreaks, 7.5%; 84 cases, 6.7%), Chongqing (16 outbreaks, 5.0%; 61 cases, 4.9%) and Bozhou, Anhui (nine outbreaks, 2.8%; 35, 2.8%). The average number (±standard deviation) of cases per outbreak was 3.92 ± 1.65. More than half (171;53.8%) of the 318 identified outbreaks involved three cases, more than a quarter (84; 26.4%) involved four cases, and only five (1.6%) outbreaks involved ten or more cases. Table S1 briefly describes four outbreaks, including the largest outbreak, which occurred in a shopping mall in Tianjin (21 cases).

Among the 318 outbreaks, 129 involved only family members, 133 involved family relatives, 29 involved socially connected individuals, 24 involved socially non-connected individuals, and only three involved multiple relationships. In addition to family members, family relatives and socially connected individuals constituted a large proportion of the infected cases (Figure 1A).

Eighty-three of the 318 identified outbreaks had multiple possible venues, which meant either that the exact venue of infection could not be identified or that more than one venue was involved in the infection. If we double- or triple-count these venues, we have a total of 416 infection venues for 318 outbreaks (Figure 1B). Among the 318 outbreaks, 254 (79.9%) occurred in a home (one in a villa; all others in apartments), 108 (34.0%) occurred on transport, 14 occurred at a restaurant or other food venue, seven occurred at an entertainment venue, and seven occurred at a shopping venue (shopping mall and supermarket), with an additional 26 occurring at a miscellaneous venue (eg, hospital, hotel room, unspecified community, and thermal power plant). Among the 235 outbreaks with an exact venue, 188 occurred in a home, 18 occurred on transport, 10 occurred at a restaurant,

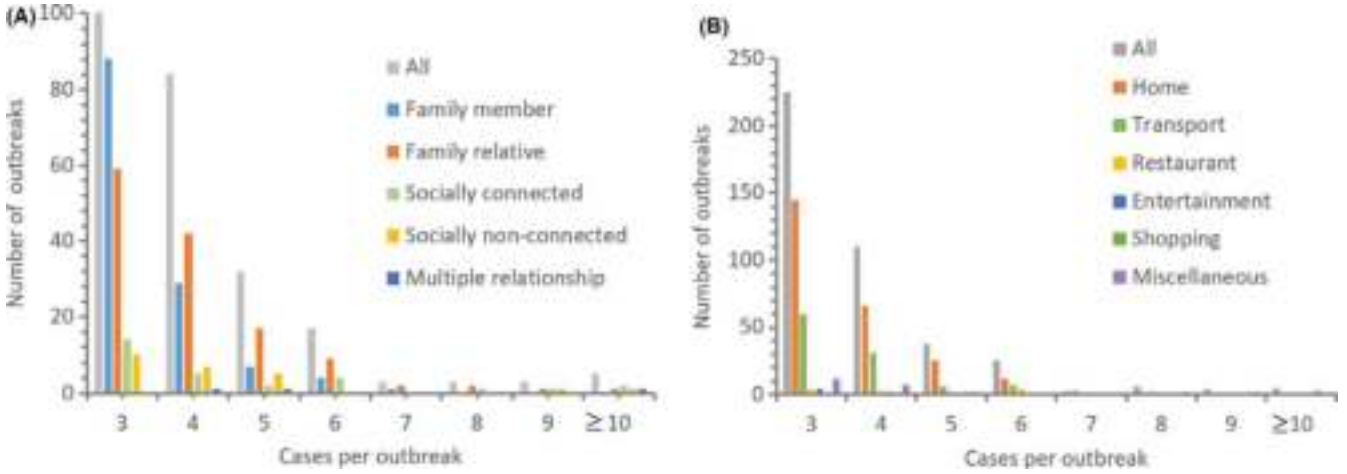

FIGURE 1 Distribution of all identified 318 outbreaks (A) involving confirmed cases of different relationships and (B) for each category of the 416 venues

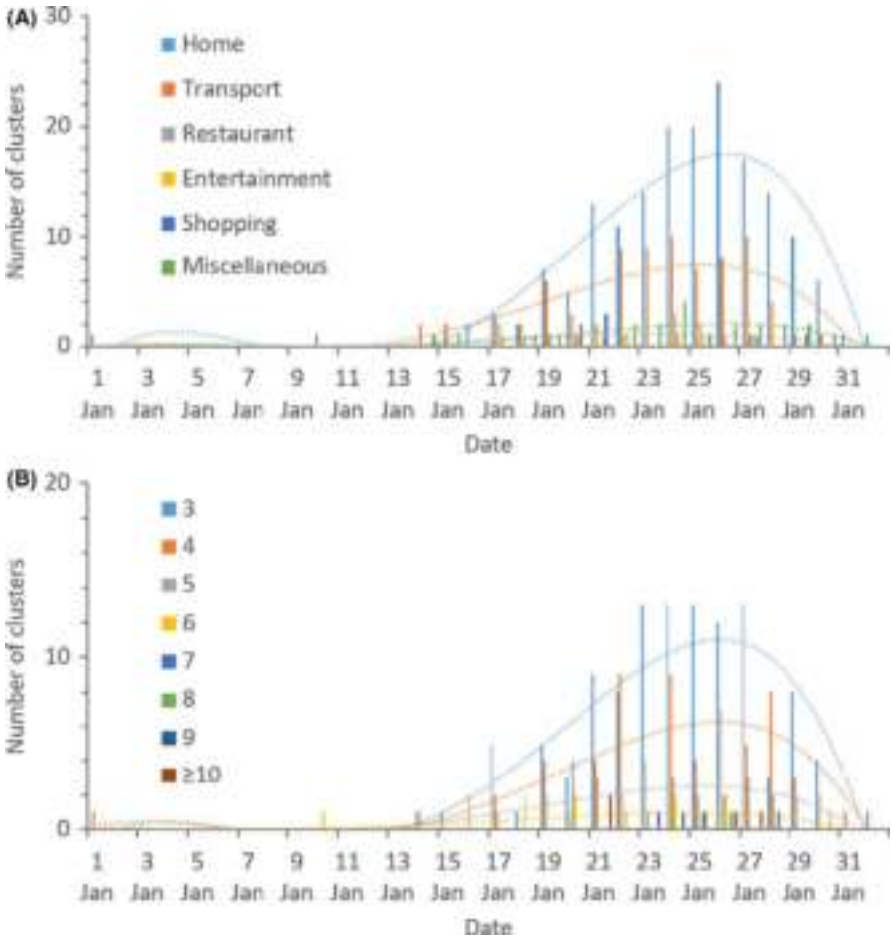
FIGURE 2 Occurrence of outbreaks on median dates of infectious period for 231 actual outbreaks (A) in different categories for 300 venues and (B) with different numbers of cases in each outbreak on median dates of infectious period



six occurred at an entertainment venue, and seven occurred at a shopping venue, with an additional six occurring at a miscellaneous venue. For the 83 outbreaks with multiple possible venues, a total of 181 venues were identified (2.18 venues per outbreak). Among the 181 venues, 66 were homes, 90 were a form of transport, 4 were restaurants, 1 was an entertainment venue, and 20 were miscellaneous venues.

Most of the 254 home outbreaks comprised three to five cases (145 with three cases, 66 with four cases, and 25 with five cases). The average number of cases was 3.7 for outbreaks at homes, 3.8 for outbreaks on transport, 4.9 for outbreaks at food venues, 3.6 for outbreaks at entertainment venues, 8.7 for outbreaks at shopping venues, and 4.4 for outbreaks at miscellaneous venues. The proportion of large outbreaks was high for shops and food venues, possibly

because more susceptible individuals were present in these venues than in homes. Shopping and entertainment venues were each associated with only seven outbreaks. This suggests that it will be difficult to implement preventive measures in places that are frequented by large numbers of susceptible individuals if exact transmission routes are uncertain. In this context, it may be useful to provide further details of the seven outbreaks in shopping venues, as these had the highest average number of cases. There was one super-spreading event (outbreak) in a shopping center involving 21 cases, and there were also two outbreaks involving 10 cases (Table S1). In these three outbreaks, two of the index patients were shopping assistants in the shopping centers and one was a vegetable trimmer in the supermarket. These were all low-end shopping venues, where we suspect that the ventilation was poor or insufficient, at least for the 21-case outbreak; however, we have no direct evidence for this. In contrast, the index patient might have been a super-spreader, because the nature of the shopping assistants' job placed them in close contact with many people for a long duration. In the third case, the virus might have been present on the raw vegetables and thus been transferred to the vegetable trimmer.

Between December 29, 2019, and January 31, 2020, we also identified 231 outbreaks with known start and end dates of the suspected infectious period (Figure 2A). The identified outbreaks peaked between January 23 and 28 (Figure 2A), which coincides with the celebration period of the Chinese New Year (CNY). CNY 2020 lasted from New Year's Eve on January 24 to the Lantern Festival (ie, the 15th of Lunar January) on February 8. The official holiday in mainland China was from January 24 to 30, 2020. The peak date for the number of transport outbreaks was 1 to 2 days earlier than that for the home outbreaks as people traveled home for CNY.

Because home outbreaks dominated, the changes in the temporal profile of the number of cases (Figure 2A) closely followed that of the home outbreaks (Figure 2B). However, for outbreaks with more than six cases, no particular pattern was identified over time, which suggests a sporadic nature.

Among the 231 outbreaks with a known suspected infectious period, 126 included a known date of symptom onset for the index patient (Figure 3). We further divided those 126 outbreaks into two subgroups according to the index patient's symptom-onset date, as follows: on or before January 28 (96 outbreaks) and after January 28 (30 outbreaks). The average time from symptom onset to the end of the infectious period was 3.76 ± 4.42 days for those on and before January 28 and 0.87 ± 2.80 days for those afterward. The significant reduction in the average time from symptom onset to the end of the infectious period between these subgroups suggests the effectiveness of the early detection and isolation policy, which also explains the sharp decline in cases of infection after January 28.

Information is available on both the age and sex of the index patient for 139 outbreaks (Figure 4). Eighty-six outbreaks (62%) had a male index case, and 53 (38%) had a female index case. The average number of infected patients (excluding the index case) was approximately 3 for most age groups (3 for minors [ie, <18 years of age], with only one outbreak; 2.79 for young adults [ie, 18-35 years of age],

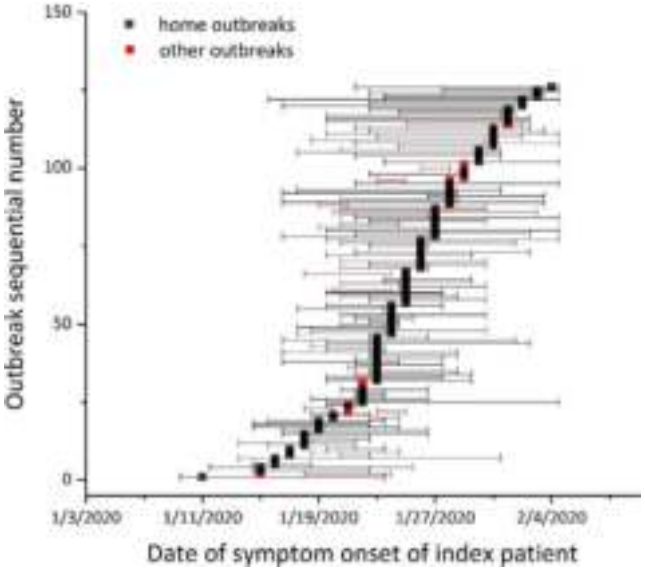


FIGURE 3 One hundred and twenty-six outbreaks with both possible starting and end infectious dates and date of symptom onset of index patient. Non-home outbreaks are shown in red

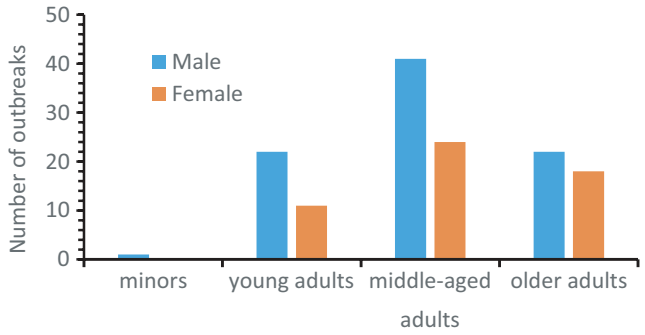

FIGURE 4 One hundred and thirty-nine outbreaks with information on the age of the index patient. Minors (<18 y old), young adults (18-35 y old), middle-aged adults (36-55 y old), senior adults (>55 y old)

in 33 outbreaks; and 3.11 for middle-aged adults [ie, 36-55 years of age], in 65 outbreaks). The average number of infected patients was 2.58 for senior adults [ie, >55 years of age], in 40 outbreaks. We were interested to note that among the outbreaks with a middle-aged index case, a female index case infected an average of 3.71 others, while a male index case infected 2.75 others. The dominant middle-aged group of reported index cases likely reflects the fact that returned migrant workers from Wuhan constituted the major pool of source patients in provinces outside Hubei.

4 | DISCUSSION

The first salient feature of the 318 identified outbreaks that involved three or more cases is that they all occurred in indoor environments. Although this finding was expected, its significance has not been

well recognized by the community or by policymakers. In a modern civilization, our lives and work are indoors. The transmission of SARS-CoV-2 from infected individuals to susceptible individuals is mainly an indoor phenomenon.

The emergence of homes as the most common COVID-19 outbreak venue in China is not surprising. During the COVID-19 epidemic in mainland China, homes became temporary quarantine places. Our estimated home dominance of 79.9% is close to the official estimate of 83% of the so-called household clusters among the nearly 1000 clusters (not outbreaks) defined by the China National Health Commission.[4] After Wuhan announced its city lockdown on January 23, the warning message spread throughout the country. People in provinces outside Hubei also began to stay at home. Most Chinese families have one child, and some families may also include grandparents. The relatively low number of cases in these home outbreaks might be considered an advantage of the compulsory home quarantine because transmission was limited to a small number of family members. Similar stay-at-home policies have now been implemented elsewhere during the pandemic. Most urban homes are high-rise apartments, while rural homes may be single-family detached houses. Modern urban homes may be mechanically ventilated, while older homes are typically naturally ventilated. It is unfortunate that detailed characteristics of the homes in which the infections occurred are not available.

The rising trend shown before the peak period in Figure 2 was likely due to the introduction of imported cases due to the Spring Festival travel season (Chunyun in Chinese), a period around CNY during which many people leave the cities in which they work to visit their rural families. The 2020 Chunyun brought people from the epicenter Wuhan to their home cities before Wuhan's lockdown on January 23. Social and family gatherings continued after January 23 in most cities outside Hubei. Interventions such as contact tracing and confinement of estates, villages, and individual buildings were implemented gradually in most cities outside Hubei immediately after CNY, which explains the sharp declining curve after January 28. The significant reduction in the average time from symptom onset to the end of the infectious period between the before January 28 subgroup and after January 28 subgroup suggests the effectiveness of the early detection and isolation policy and explains the sharp decrease in infections after January 28.

Our study does not rule out outdoor transmission of the virus. However, among our 7324 identified cases in China with sufficient descriptions, only one outdoor outbreak involving two cases occurred in a village in Shangqiu, Henan. A 27-year-old man had a conversation outdoors with an individual who had returned from Wuhan on January 25 and had symptom onset on February 1. This outbreak involved only two cases.

The second salient feature of the 318 identified outbreaks is the relatively small number of outbreaks that involved 10 or more cases. The largest outbreak occurred in a Tianjin shopping mall and involved 21 cases, although Wu et al[5] reported 25 cases (Table S1). This is distinct from the 2003 SARS-CoV epidemic, during which seven major super-spreading events in Hong Kong and Singapore alone were identified to involve as many as 329 cases and super-spreading events dominated the epidemic.[6] The occurrence of many small outbreaks (in terms of the number of cases) in the COVID-19 pandemic suggests a different transmission pattern from that of the 2003 SARS-CoV epidemic. Some viral, epidemiological, and environmental factors may have contributed to this difference between the 2003 SARS-CoV epidemic and the current COVID-19 pandemic. However, a number of large super-spreading events were later reported elsewhere in the world, including 94 people who were infected in an 11th-floor call center in Seoul with 216 employees,[7] and 32 confirmed and 20 probable secondary cases after a 2.5-hour choir practice attended by 61 persons in Skagit County, Washington.[8] We cannot pinpoint the exact transmission routes of these identified outbreaks. During the early phase of the pandemic, most health authorities advised that the SARS-CoV-2 was transmitted mainly by close contact and via the fomite route (eg, China NHC[9] and US CDC[10]). The China NHC also suggested that long-range aerosol transmission may occur when certain conditions are met, such as in crowded enclosures or spaces with poor ventilation. By 5 November 2020, the US CDC[11] suggested that "It is possible that COVID-19 may spread through the droplets and airborne particles that are formed when a person who has COVID-19 coughs, sneezes, sings, talks, or breathes. There is growing evidence that droplets and airborne particles can remain suspended in the air and be breathed in by others, and travel distances beyond 6 feet (for example, during choir practice, in restaurants, or in fitness classes). In general, indoor environments without good ventilation increase this risk."

We do not have data on the hygiene conditions, such as ventilation rates and human densities, of the infection venues of the 318 outbreaks studied here. The exact location of the infection venues and the necessary parameters such as the floor area or the number of occupants were not provided in the case reports. Instead, we reviewed the current design standards of thermal and ventilation conditions, occupant density, and close-contact behavior in the various indoor environments discussed here (Table S3). The required ventilation rates vary significantly among homes, offices, trains, and buses. We note that the current ventilation rate guidelines in these environments do not consider infection control. For example, the required ventilation rate is only 3.9 L/s per person in shopping malls and 2.8 L/s per person in public buses, whereas a ventilation rate of at least 8-10 L/s is required for good indoor air quality.[12] The review showed that a rate as high as 25 L/s per person may be needed.[12] Some existing buildings are probably crowded, poorly ventilated, and unhygienic. A comprehensive review of ventilation conditions in Chinese indoor environments by Ye et al[13] showed that the CO_2 concentration can reach 3500 pp min some buildings. The design and operation of buildings have also been under pressure to reduce energy use[14] and increase human productivity. Balancing the need for energy efficiency, indoor environmental quality and health in both urban planning and building design have not been easy.[15] The quality of indoor environments might be sacrificed by putting a greater focus on cost than on health.

Close-contact behavior and occupant density in the various indoor environments discussed are also reviewed in Table S3. Frequent close contact occurs indoors, and buildings have high-touch surfaces.[16-19] Unfortunately, we do not have detailed data on surface-cleaning and hand-hygiene conditions in these indoor environments, but fomite transmission must nevertheless be considered in designing preventive approaches.

This study has limitations. We only studied outbreaks in China, where very strict intervention measures were implemented. We relied fully on the case reports of the local health authorities in each city, and variation exists in the details and the quality of their original epidemiological investigations. We also made no attempt to access any of the infection venues, and the details of each of these indoor spaces remains unknown.

This study shows that the individual indoor environments in which we live and work are the most common venues in which the virus of the once-in-a-century-pandemic is transmitted among us. An individual infected in one building may infect others in the building(s) that he or she later visits. People are in constant contact as they move from one indoor space or building to another, which creates an indoor contact network through which a virus can spread.[20] The buildings and transport cabins in various parts of the world are thus connected and facilitated the spread of the COVID-19 pandemic virus.

The association between crowding and infection has been known since Pringle.[21] The most dramatic example in the current pandemic might be in the cruise ship outbreak on the crowded Diamond Princess, of which the peak basic production number was predicted to be 11[22] or 14.8[23] before quarantine and much higher than elsewhere. The world's first statutory housing policy, the Artisans and Labourers Dwellings Act 1875[24] was developed following 19th-century empirical evidence that crowding led to a high incidence of infectious disease. A recent systematic review by the World Health Organization also found an association between crowding and infection.[25] A *Lancet* editorial in 2018 declared "[t]he right to a healthy home."[26] One WHO meeting also declared that "everyone has the right to breathe healthy indoor air"[27] and that "the provision of healthy indoor air should not compromise global or local ecological integrity, or the rights of future generations".[28] We hope that in the post-pandemic future, mankind will reflect deeply on the need for a healthy indoor environment.

ABSTRACT

The COVID-19 disease spread at different rates in the different countries and in different regions of the same country, as happened in Italy. Transmission by contact or at close range due to large respiratory droplets is widely accepted, however, the role of airborne transmission due to small respiratory droplets emitted by infected individuals (also asymptomatic) is controversial. It was suggested that outdoor airborne transmission could play a role in determining the differences observed in the spread rate. Concentrations of virus-laden aerosol are still poorly known and contrasting results are reported, especially for outdoor environments. Here we investigated outdoor concentrations and size distributions of virus-laden aerosol simultaneously collected during the pandemic, in May 2020, in northern (Veneto) and southern (Apulia) regions of Italy. The two regions exhibited significantly different prevalence of COVID-19. Genetic material of SARS-CoV-2 (RNA) was determined, using both real time RT-PCR and ddPCR, in air samples collected using PM_{10} samplers and cascade impactors able to separate 12 size ranges from nanoparticles (diameter D < 0.056 μm) up to coarse particles (D > 18 μm). Air samples tested negative for the presence of SARS-CoV-2 at both sites, viral particles concentrations were <0.8 copies m^{-3} in PM_{10} and <0.4 copies m^{-3} in each size range investigated. Outdoor air in residential and urban areas was generally not infectious and safe for the public in both northern and southern Italy, with the possible exclusion of very crowded sites. Therefore, it is likely that outdoor airborne transmission does not explain the difference in the spread of COVID-19 observed in the two Italian regions.

1. Introduction

The pandemic of COVID-19 disease, due to the novel coronavirus SARS-CoV-2, was firstly reported in a cluster in Wuhan (China) in December 2019 and it rapidly spread all around the World. By June 27 (2020), infected cases reached 9,660,902 individuals and 491,195 deaths worldwide (https://covid19.who.int/). Starting from February 2020 it was clear that spread of the disease happened in specific outbreak areas and that significant differences were observed in COVID-19 prevalence and fatality rate in different countries and in different regions of the same country. In Europe, Italy was the first country severely hit, with the majority of cases observed in northern Italy and a much smaller number of cases observed in central and, especially, southern Italy. The rapid spread of SARS-CoV-2 and these spatial differences raised important questions regarding the mechanisms of transmission and the role potentially played by airborne transmission. It has also been suggested that airborne transmission could be responsible of the different COVID-19 prevalence observed in northern and southern Italy because of the different dispersion conditions in the two areas (Conticini et al., 2020; Setti et al., 2020). The Po Valley area in northern Italy is characterised, especially during winter period, by low wind speed accompanied to long periods of stable conditions with shallow mixing layers (Ferrero et al., 2010) and this limit both transport (because of limited ventilation) and dispersion of pollutants (because of limited turbulence) favouring large pollutant concentrations near the ground. Venice area, in the northeast of Italy is located near the sea and it has a typical circulation of air masses (Contini et al., 2015) with prevalent winds coming from NNE-NE directions (from the Alps

mountains) mainly during the night and winds coming from SSE-SE during the day (from the Adriatic Sea). In contrast, Apulia region in southern Italy has a local meteorology characterised by greater solar radiation, compared to the Po Valley, increasing thermal turbulence and strong winds that favour transport and dilution of pollutants (Cesari et al., 2018). This difference in dispersion conditions could, in principle, influence the concentrations of virus-laden particles in outdoor air.

The spread of SARS-CoV-2 by contact (direct or indirect through contaminated surfaces) is widely accepted, however, the relative importance of airborne transmission is still controversial (Contini and Costabile, 2020; Domingo et al., 2020; Klompas et al., 2020; Morawska and Cao, 2020; Prather et al., 2020). Particles are emitted during sneezes, cough, respiration, speaking, singing, and shouting. In case of infected individuals, these particles could contain viable virus as happens for other respiratory viruses (Milton et al., 2013; Yan et al., 2018), including other coronaviruses such as NL63, OC43, 229E, and HKU1 (Leung et al., 2020). Sneezing and coughing are mainly associated with symptomatic individuals, however, emissions during respiration and speaking could happen also for asymptomatic individuals that have typically a viral load comparable to that of symptomatic patients (Lavezzo et al., 2020). Large respiratory droplets (conventionally with diameter $D > 5$ μm) settle faster than they evaporate, contaminating the immediate vicinity of the infected individuals. In contrast, small droplets (i.e. $D < 5$ μm) evaporate faster than they settle, leaving dry residuals (also called droplet nuclei) which might contain virus aggregates, proteins, and mineral salts (Asadi et al., 2020; Borouiba, 2020). Droplet nuclei can remain suspended in air for longer time compared to large droplets and potentially contribute to airborne transmission (Allen and Marr, 2020; Morawska and Cao, 2020; Martano, 2020).

The probability of airborne transmission is different in outdoor and indoor environments and depends on several parameters; the most important are: (i) concentration and size distribution of virus-laden particles in air; (ii) the fraction of viable viral particles; (iii) the minimum viral load necessary to transmit the infection by inhalation in susceptible individuals. The lifetime of aerosolized SARS-CoV-2 could be 3 h under laboratory controlled conditions (van Doremalen et al., 2020), but it could be less in outdoors depending on the degradation of the virus due to local meteorology conditions (Ratnesar-Shumate et al., 2020). The minimum infectious dose, expressed in viral RNA copies inhaled, is not defined for SARS-CoV-2 in current scientific literature. However, referring to the studies on SARS-CoV-1, the dose of airborne virus copies (i.e. the quantum) necessary to cause infection in 63% of susceptible individuals is variable between 10 and 100 and it is possible to assume an average of 20 for SARS-CoV-2 (Buonanno et al., 2020). Current knowledge of concentration and size distribution of virus-laden aerosol in air is extremely scarce and contrasting results have been observed. In outdoors, measurements in Wuhan (Hu et al., 2020; Liu et al., 2020) showed concentrations below the detection limit, except for crowded areas; while, a study conducted in Bergamo (north of Italy) identified traces of viral RNA in 23% of the analysed PM_{10} samples without quantifying the concentrations (Setti et al., 2020). Concentrations of viral particles in indoor environments (mainly measured in hospitals and quarantine areas) seems to be higher (Hu et al., 2020; Liu et al., 2020; Santarpia et al., 2020) than those observed in outdoors. However, other studies showed no detectable concentrations even in proximity of quarantined COVID-19 patients (Faridi et al., 2020; Ong et al., 2020).

This work tries to fill the gap in knowledge regarding atmospheric concentrations of virus-laden particles in Italy. It is focused on the analysis of concentration and size distribution of SARS-CoV-2 virus-laden aerosol in outdoor air, comparing data collected in the Veneto region (north Italy) and Apulia region (south Italy), to asses a possible role of outdoor airborne transmission in the difference of COVID-19 spread rate observed in north and south of Italy. Measurements were performed simultaneously in the two regions, collecting air samples using both PM_{10} samplers and cascade impactors. SARS-CoV-2 presence was determined looking for genetic material (RNA) using both real-time RT-PCR and droplet digital PCR (ddPCR) methods (Corman et al., 2020; Suo et al., 2020).

2. Methods

2.1. Samples collection

Aerosol sampling was simultaneously carried out from 13th to 27th of May 2020, in two different Italian regions: Veneto (in the northeaster Italy) and Apulia (in the southeaster Italy). In Veneto, samples were collected at the Scientific Campus of Ca' Foscari University (45°28′47″N, 12°15′12″E, Mestre-Venice, Italy). The site is located in a working/residential area of Mestre, characterized by some major potential sources of particulate matter: high density residential areas; heavily trafficked roads; the industrial area of Porto Marghera, and an international airport (Squizzato et al., 2016). In Apulia, measurements were performed at the Lecce Environmental-Climate Observatory (ECO, 40.3°N 18.1°E; 36 m a.s.L.), located at the Institute of Atmospheric Sciences and Climate of the National Research Council (ISAC-CNR), inside the University Campus, at about 4 km (WSW) from the urban area of Lecce (Dinoi et al., 2020). The area, considered an urban background site, is affected by the integrated contribution of local anthropogenic sources (mainly road traffic and biomass burning) and by the long-range transport of natural and anthropogenic dust (Cesari et al., 2016, 2018).

During both sampling campaigns, two different samplers were used. In Venice, PM_{10} samples were collected using a low volume aerosol sampler (Skypost PM-TCR Tecora) equipped with a sequential sampler (Charlie) that operates at flow rate of 38.3 L min^{-1}. The sampling period for each sample was about 48 h, with a total average air volume of 110 m^3 per sample. A second simultaneous sampling was performed using a model 110 MOUDI cascade impactor with an average flow of 30 L min^{-1}. The inlet of the impactor has a nominal cut-off size of 18 μm, and the nominal cut-off sizes of the 10 impaction stages are: 10, 5.6, 3.2, 1.8, 1.0, 0.56, 0.32, 0.18, 0.10 and 0.056 μm. A back-up filter collected particles with aerodynamic diameter <0.056 μm. The sampling period for each impactor sample was about 6 days, with a total average air volume of about 250 m^3 per sample. This setup for data collection with the impactor was already successfully used in other measurement campaigns (Cesari et al., 2020).

In Lecce, the 48-h PM_{10} samples were collected using a low volume (38 L min^{-1}) sampler (SWAM 5a Dual Channel Monitor-FAI Instruments). Size-segregated samples were collected with a rotating model 120 MOUDI-II™ cascade impactor, operating at 30 L min^{-1} for about 6 days for each sample, to separate particles of different aerodynamic diameters in the same twelve intervals used in the Venice site.

At both sites, quartz fibre filters were used, after a decontamination process with a 4 h pre-combustion at 400 °C in a muffle furnace. In total, 12 PM_{10} filters (6 for each site) and 48 impactor filters (24 for each site) were collected. In addition, 4 field blank filters were obtained for each site, 2 for the PM_{10} sampler and 2 for the cascade impactor. All samples were vacuum packed in sealed sterile petri dishes and frozen at −25 °C immediately after sampling for conservation until the successive analysis. Laboratory analysis started within four days from the end of collection period.

It has been chosen to use both, PM_{10} samplers and cascade impactors, because it is important to know the size distribution of virus-laden particles to effectively understand the risk of airborne transmission. Sub-micrometric particles (in the accumulation mode <1 μm) could remained suspended in atmosphere for longer time compared to larger particles that have a greater deposition velocity. Therefore, particles in the accumulation mode could contribute to airborne transmission more than coarse particles and there are limited indication on this aspect in current studies. In Liu et al. (2020) in indoor environments in hospitals in China SARS-CoV-2 RNA was detected also in the size range 0.25–1 μm, instead, in the indoor measurements in Singapore hospitals (Chia

et al., 2020) the smallest aerodynamic size fraction that contained detectable levels of SARS-CoV-2 was 1–4 μm.

2.2. Analytical method for RNA detection

RNA extraction for PCR experiments was achieved using Total RNA Purification Kit (Norgen Biotek Corp.) with a modified protocol to increase yield. Each filter was cut and placed inside a 2 mL centrifuge tube containing 1 mL of Phosphate Buffer Solution (PBS) pH 7.4. The tube was sealed and put in a sonicator water bath (Elmasonic S10H) for 30 min. Aerosol particles were separated from the quartz filter by centrifugation using a mini syringe placed in a collection tube. The obtained pellet, for each filter processed, was resuspended by 350 μL of supernatant, according to the manufacturer's protocol. The final eluted solutions (about 70 μL in total) were stored frozen at −80 ± 2 °C until PCR analysis that was performed within four days from extraction.

Molecular analysis for the detection of SARS-CoV-2 was carried out using real-time RT-PCR and Droplet Digital PCR (ddPCR) technologies. According to World Health Organization (WHO), real-time RT-PCR represents the gold standard for the diagnosis of SARS-CoV-2. Recently, ddPCR has demonstrated the best performance to detect SARS-CoV-2, because it reduces the false negatives (Suo et al., 2020).

Real-time RT-PCR for SARS-CoV-2 was carried out on a CFX96™ Real-Time system (Bio-Rad, Italy) using COVID-19 PCR DIATHEVA Detection kit (Diatheva, Cartoceto, PU, Italy) based on the WHO guideline (Corman et al., 2020). The COVID-19 PCR DIATHEVA Detection kit is a One-Step real-time reverse transcription (RT-PCR) multiplex assay based on fluorescent-labelled probe used to confirm the presence of SARS-CoV-2-RNA by amplification of RdRp and E gene. The kit provides all the reagents required for the analysis, PCR positive and PCR negative controls included. 5 μL of extracted RNA were added to 15 μL of Master mix for each sample and analysed according to kit instructions. Undiluted and 1:10 diluted samples were tested. In each run, two negative controls (molecular grade water) and a positive control were added. The interpretation of the sample results was done according to kit instructions. The limit of detection (LOD) of the COVID-19 PCR DIATHEVA Detection kit was previously defined through analysis of standard material RNA of SARS-CoV-2 and was equal to 10 copies/μL.

The ddPCR assays were performed using Bio-Rad SARS-CoV-2 ddPCR kit on QX200™ Droplet Digital™ PCR system (Bio-Rad, Italy). The Bio-Rad SARS-CoV-2 ddPCR is a reverse transcription (RT) droplet digital PCR (ddPCR) test designed for the qualitative detection of RNA from SARS-CoV-2. The assay includes the 2019-nCoV CDC ddPCR Triplex Probes and the One-Step RT-ddPCR Advanced Kit for Probes. The 2019-nCoV CDC ddPCR Triplex Probes contains specific oligonucleotide primers and probes for SARS-CoV-2 (N1 and N2), the same as those reported by Center for Disease Control and Prevention (CDC), mapping on regions of the virus nucleocapsid (N) gene into a single assay multiplex to enable a one-well reaction. The reaction mixtures were partitioned into approximately 20,000 droplets using a QX200 Droplet Generator™ (Bio-Rad, Italy) with the random dispersal of target nucleic acids into the droplets. The PCR assays were conducted in a C1000 Touch™ Thermal Cycler (Bio-Rad, Italy), according to kit instructions. After amplification, the droplets were individually assayed using the QX200™ Droplet Reader™. The fluorescence data were then analysed by the QuantaSoft v1.7 Software and QuantaSoft Analysis Pro v1.0 Software (Bio-Rad, Italy) to determine the presence of SARS-Cov-2 N1 and N2 in the specimen. The LOD of the Bio-Rad SARS CoV-2 ddPCR test was declared by the manufacturer in 0.625 copies/μL for targets N1 and N2.

The efficiency of the extraction procedure was evaluated through the recovery of a process control, a virus added prior to acid nucleic extraction. Mengo virus strain MC_0, supplied by Istituto Superiore di Sanità (ISS, Rome, Italy), is a murine virus of the *Picornaviridae* family, a non-enveloped positive-sense ssRNA virus. The efficiency of the extraction method was evaluated comparing the Ct values obtained for Mengovirus on samples extracts. In detail, 10 μL of Mengovirus was added prior to extraction to (i) 1 mL of PBS (reference sample); (ii) 1 mL of PBS with a blank filter and (iii) 1 mL of PBS with an exposed environmental filter. Each condition was run in duplicate. The detection of Mengovirus was carried out on a CFX96™ Real-Time system (Bio-Rad, Italy) using amplification conditions, primers and probe and reagents RNA UltraSense™ One-Step Quantitative RT-PCR System (Life Technologies, Carlsbad, California, US) (Pintó et al., 2009). Results indicate an average recovery of 49% (±5%).

3. Results and discussion

The outbreak of COVID-19 in Italy has resulted in 239,961 confirmed cases and 34,708 fatalities as of 27th June 2020. The transmission of SARS-CoV-2 was exceptionally severe in Veneto region (Fig. 1), with maximum active cases (i.e. currently infected individuals) of 10,800 on 16th April (about 10% of the overall Italian cases) over a population of 4.9 million people. Apulia region (southern Italy) reached the maximum of active cases on the 3rd of May with 2,955 cases (3% of the overall Italian cases) over a population of 4.0 million people. At the beginning of sampling period (13th May) Veneto and Apulia regions were affected by 5,020 and 2,322 active cases, respectively. These official numbers likely underestimate the real contagions. In Italy, cumulatively, 2.2–3.5 million individuals seem to have been infected as of May 4th, giving an attack rate of 3.6%-5.8% of the population (Flaxman et al., 2020).

During sampling, the average temperature was 19.6 °C (±1.4 °C) in Venice and 21.0 °C (±1.9 °C) in Lecce; the average relative humidity was 69% (±9.5%) in Venice and 56% (±9.8%) in Lecce. No precipitations were observed at the two sites during the sampling period.

PM_{10} and $PM_{2.5}$ concentration levels at the two sites are shown in Fig. 2. The national lockdown in Italy (indicated as phase I) included the period between 10th March and 17th May, even if there were some differences of restrictive measures during this period. Successively, there was the post-lockdown divided in what we called phase II and phase III in Fig. 2. Phase II was from 18th May until 3rd June and it was a re-opening with several limitations (cinema and theatres closed, travels among different regions were interdict, employees of public administrations remained diffusely on smart working). During phase III it was removed the restriction of travels among different regions and a significant fraction of employees of public administrations started to work on offices again. Our measurements started near the end of the phase I and continued during phase II of the post-lockdown period. The concentrations of PM_{10}, averaged over the whole measurement period, were 17.2 ± 5.2 μg m^{-3} (average ± standard deviation) in Venice, as provided by the Regional Agency of Environmental Prevention and Protection of Veneto (ARPAV) and 27.0 ± 14.8 μg m^{-3} in Lecce. The average concentrations of $PM_{2.5}$ were 9.8 ± 2.5 μg m^{-3} in Venice and 8.3 ± 2.3 μg m^{-3} in Lecce. High PM_{10} concentration are determined in Lecce at the beginning of sampling period (13–18 May 2020), while the values of $PM_{2.5}$ were comparable at the two sites (Fig. 2). This was due to a contribution of coarse particles due to African dust advection, that influenced only southern regions of Italy, contributing mainly to PM_{10} but not significantly to $PM_{2.5}$.

The existence of SARS-CoV-2 in aerosol samples was determined through the detection of its genetic material (RNA) in collected samples. Air samples were extracted at the Istituto Zooprofilattico Sperimentale della Puglia e della Basilicata (IZSPB), COVID-19 laboratory for the Apulia region. All extracts were firstly analysed using real-time RT-PCR and were negative showing no detectable presence of SARS-CoV-2 RNA. The detection limit of the method, referred to the extracted solutions, was 10 genome copies μL^{-1}. Successively, the same extracts were also analysed using the most sensitive technique available in the laboratory, the ddPCR, lowering the detection limit to 0.625 genome copies μL^{-1} and all samples tested negative for the presence of viral RNA.

The LODs (genome copies μL^{-1}) were transformed in thresholds for atmospheric concentrations of viral particles (expressed in copies/m^3)

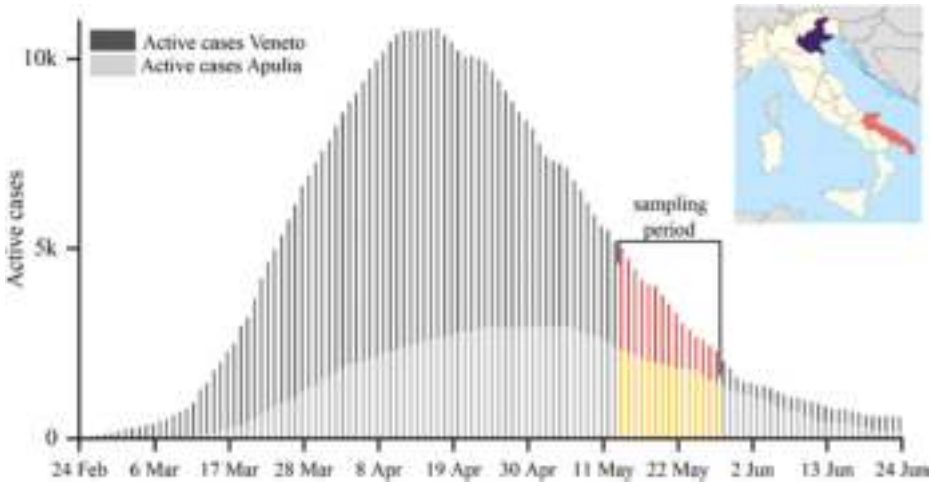

Fig. 1. Daily number of infected individuals observed in Veneto and Apulia regions during COVID-19 outbreak in Italy. The measurement sites are shown together with sampling period.

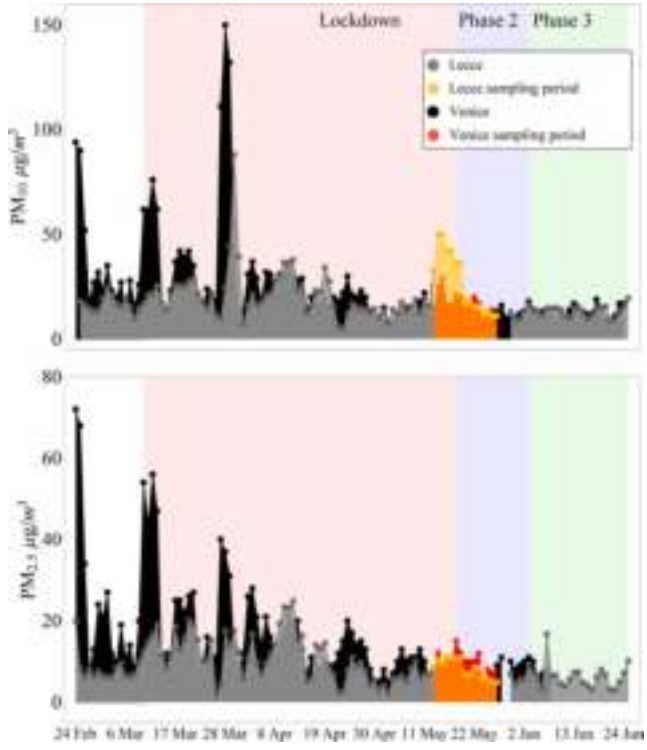

Fig. 2. Comparison of PM_{10} (top) and $PM_{2.5}$ (bottom) concentrations at the two sites evidencing the sampling period. The lockdown period (phase I) and the post-lockdown (phase II and II) are reported.

using the same approach employed for determination of concentration threshold of a chemical component of aerosol samples. Specifically, the LOD was transformed in a threshold of viral particles contained in a single filter (i.e. RNA copies per filter) considering the total volume of extraction solutions (about 70 μL) and the efficiency of the methodology (i.e. the recovery). These numbers were then normalised using the sampled volume to obtain the concentration threshold in copies m^{-3}. The concentration of virus-laden aerosol in PM_{10} samples was <0.8 copies m^{-3} at both sites during the sampling period. The size-segregated concentrations from nanoparticles ($D < 0.056$ μm) up to coarse particles ($D > 18$ μm) were <0.4 copies m^{-3} at both sites.

These results are comparable with those found in outdoor residential area in Wuhan (China) during the pandemic (Liu et al., 2020). Liu et al. (2020) collected air samples suing both samplers and cascade impactors, between February and March 2020, in public areas in outdoor as well as in indoor in quarantine areas. Samples collected in outdoor residential areas tested negative (<3 copies m^{-3}) with the exclusion of crowded zones in proximity of hospitals in which concentrations up to 11 copies m^{-3} were detected. Hu et al. (2020) found no viral RNA in air samples collected in residential community and an open public area (not crowded sites) in Wuhan (China). The analysis reported by Setti et al. (2020) shows that 23% of the 34 PM_{10} samples collected between February and March in outdoor in northern Italy (Bergamo) tested positive for SARS-CoV-2 RNA, however, concentrations of virus-laden particles were not evaluated. Results reported here suggest that in outdoor conditions, and excluding crowded areas, it is unlikely a role of airborne transmission of COVID-19.

The risk could be larger in community indoor environments where a certain number of infected individuals could be present in closed environments with limited ventilation. In this case, concentrations of virus-laden aerosol seems to be larger compared to outdoor, even if some contrasting results have been obtained. Liu et al. (2020) found SARS-CoV-2 RNA concentrations up to 42 copies m^{-3} in hospitals and quarantine areas in Wuhan (China) with a fraction of these viral particles in the fine size range (0.25–1 μm). Chia et al. (2020) found detectable SARS-CoV-2 genetic material in air in indoor COVID-19 patient care areas in Singapore in the size range >1 μm. Lednicky et al. (2020) found viable SARS-CoV-2 was isolated from air samples collected 2 to 4.8 m away from the patients in samples collected at the Student Health Care Center (SHCC, University of Florida, USA). Santarpia et al., 2020 found detectable concentrations of viral RNA in 63% of the samples collected in indoor at the Medical Center of the University of Nebraska (where COVID-19 patients were quarantined) with concentrations up to 2.86 copies L^{-1}). Instead, Faridi et al. (2020) did not detect SARS-CoV-2 in ten air samples collected in patient rooms of the largest hospital in Iran. In Singapore, air samples collected in a quarantine area with three patients tested negative for the presence of SARS-CoV-2 RNA (Ong et al., 2020). The possible larger risk of community indoor environments compared to outdoors could be mitigated by the use of face masks and the ventilation of closed spaces with outdoor air.

4. Conclusions

The results found indicate that outdoor atmospheric concentrations of SARS-CoV-2 were very small (<0.8 copies m^{-3}) in both northern and southern Italy. The same applies for each size range investigated with the impactor, which gave virus-laden aerosol concentrations <0.4 copies m^{-3}. The measurements were taken in a period when the number

of active cases (i.e. infected individuals) in the two regions were not at the maximum values (Fig. 1), thereby, it is possible to assume that higher concentrations (up to a factor 2 on average for Venice) were likely be present during the period of maximum spread of contagion. The average typical threshold of about 20 virus copies is necessary (Buonanno et al., 2020) to make a quantum of virus (i.e. the dose of airborne droplet nuclei that, if inhaled, is able to cause infection in 63% of susceptible persons). Considering a typical inhalation rate of about 1 m^3/h, as average between rest and light exercise (Adams, 1993), the concentrations would be low to spread the contagion via airborne transmission even assuming the mentioned increase of a factor 2.

Therefore, it is possible to conclude that outdoor air in residential and urban areas was generally not infectious and safe for the public in both northern and southern Italy, with the possible exclusion of very crowded sites. In addition, outdoor airborne transmission of SARS-CoV-2 was likely not the main cause of the difference in diffusion rates of COVID-19 observed during outbreaks in north and south of Italy.

Author contributions

D. Contini, A. Gambaro, G. La Salandra conceptualized the study design; E. Barbaro, E. Gregoris, M. Feltracco collected samples in Venice and contributed to data post-processing; M. Conte, A. Dinoi collected samples in Lecce and contributed to data post-processing; D. Chirizzi, G. Ciccarese, G. La Salandra, and G. La Bella carried out the laboratory tests. All authors collaborated to interpretation of results, wrote, read, commented, and approved the final manuscript.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Acknowledgements

This study did not receive specific funding and was performed within the cooperation project AIR-CoV (Evaluation of the concentration and size distribution of SARS-CoV-2 in air in outdoor environments). Authors wish to thank Arpa Veneto for furnishing their meteorological and particulate matter measurements in Venice area.

ONTARIO
SUPERIOR COURT OF JUSTICE

B E T W E E N:

THE ATTORNEY GENERAL OF ONTARIO

Applicant (Responding Party)

-and-

TRINITY BIBLE CHAPEL, JACOB REAUME, WILL SCHUURMAN, DEAN WANDERS, RANDY FREY, HARVEY FREY and DANIEL GORDON

Respondents (Moving Parties)

A N D B E T W E E N:

HER MAJESTY THE QUEEN IN ONTARIO

Applicant (Responding Party)

-and-

THE CHURCH OF GOD (RESTORATION) AYLMER, HENRY HILDEBRANDT, ABRAM BERGEN, JACOB HIEBERT, PETER HILDEBRANDT, SUSAN MUTCH, ELVIRA TOVSTIGA, and TRUDY WIEBE

Respondents (Moving Parties)

AFFIDAVIT OF DR. RICHARD SCHABAS
(Sworn May 29, 2021)

I, RICHARD SCHABAS, of the [redacted] in the Province of Ontario, MAKE OATH AND SAY:

1. I am a retired physician with specialist qualification in Public Health, and as such have knowledge of the matters hereinafter deposed to.

2. I also have specialist qualification in Internal Medicine and a Master's degree in Epidemiology. I practised clinical medicine for forty years, initially as a general practitioner and then as a general internist. I practised public health for twenty-five years at a local and provincial level, including ten years as Ontario's Chief Medical Officer of Health, between 1987 and 1998.

3. I worked in hospital management as Chief of Staff at York Central Hospital and was directly involved in the 2003 SARS outbreak. I have held academic appointments at three Ontario universities - Toronto, Waterloo and Queen's. I gave testimony at three Royal Commissions on public health issues - the Krever Commission on blood safety, the O'Connor Commission on Walkerton and the Campbell Commission on SARS. I have contributed to 28 peer reviewed published papers.

4. My curriculum vitae is attached hereto and marked as **Exhibit "A".**

5. The Moving Parties' counsel contacted me about providing expert testimony in support of their motion to set aside the enforcement order against them. I have been asked to address the following issues surrounding the virus SARS-CoV-2 and Covid-19 disease:

    a. **Data analysis** -- How serious is Covid-19? How does it compare to previous pandemics? What does the data tell us about who this disease is impacting? Can you put this into context so we can understand the severity of Covid across various demographics and relative to other causes and numbers of deaths?

    b. **Public health & policy** -- Do current public health responses reflect the data and analysis noted in your answer to question 1? What should public health be concerned with? Have our "lockdown" measures been in keeping with previous public health practices, standards and plans for

pandemic management? Are population-wide lockdowns an appropriate public health response? If not, why not?

c. **Lockdown harms** -- Has an appropriate cost/benefit analysis been done by the government? Do lockdowns work in preventing unnecessary mortality? What are the unintended or ignored secondary consequences and harms? What are the public health concerns with curtailing the activities of healthy people or those with limited risk?

d. **Limits on gatherings** -- Should Ontarians be allowed to attend religious services, gather with their families and friends, go to restaurants or small businesses, and peacefully protest? What is the data on outbreaks in these settings? Do we know whether this translates into hospitalizations and/or deaths? Is a limit of 10-persons based on any scientific and evidentiary foundation? Is it appropriate, from a public health perspective, for governments to make all decisions on risk assessment or tolerance on behalf of individual citizens?

6. I acknowledge that in preparing this report and providing expert evidence, the Moving Parties' counsel explained that my role is to assist the court to determine the matters in issue. I further acknowledge that it is my duty to provide evidence that is fair, objective and non-partisan and to opine only on matters that are within my area of expertise. This duty prevails over any obligation that I may owe to any party on whose behalf I am engaged.

7. Covid-19 is a novel respiratory virus that has caused a global outbreak over the past 16 months. Public health has been preoccupied by its response to Covid-19. The issues around Covid-19 are complex and much of the science is uncertain. Ontario has responded to Covid-19 with a variety of restrictive measures generally characterized as "lockdown". Many of these measures have been arbitrary and capricious. I will focus on the specific issue of restricting the size of religious gatherings.

8. “Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity.”[1] A wholistic view of health has long been a cornerstone of public health practice. For the past year public health in Ontario has obsessed with controlling just one disease to the detriment of all other diseases and other aspects and determinants of health. The ability to practice religion in a time-honoured fashion is important to the mental and social well-being of many people. Not allowing some people to practice their religion in person is bad for their health.

9. “First do no harm.”[2] Many lockdown measures, including restrictions on normal religious practices, cause substantial harm. When a medical intervention can cause harm there is an onus to show strong evidence that the intervention is both necessary and is effective. Furthermore, there is a responsibility to take all reasonable measures to mitigate the harms from the intervention. There is no strong evidence that limiting the size of religious gatherings is necessary and effective to control Covid-19. Ontario public health has rigidly applied the same rules to all public gatherings regardless of the relative harms.

10. The measures broadly described as lockdown were mostly invoked in a period of panic in March 2020. Covid-19 was suddenly and unexpectedly causing large outbreaks in Western Europe and, in Italy at least, threatened the integrity of health care. Spurious mathematical models posited a microbiological apocalypse with tens of millions of deaths in a matter of a few months. China first and then Italy locked down. And then, in a matter of days, so did we. We did this without any substantial scientific foundation, and we did it without any clear idea of our goals and objectives other than a vague notion of “flattening the curve”.

11. Public health has relied heavily on mathematical models in its Covid response. These models are inherently simplistic and are dependent on unreliable inputs.[3] The most contentious input into the models was (and is) the estimate of the Infection Fatality Rate (IFR). The models that drove our response in Covid-19 used IFR estimates of about 1% (one in one hundred). Analysis based on

seroprevalence studies shows that the actual IFR was much lower at 0.23% or less.[4] Perceptions, however, remained anchored at a much higher rate. For example, Dr. David Fisman, a prominent Canadian modeller, in his testimony to the Health Committee of the House of Commons on May 20, 2020, a transcript of which is attached hereto and marked as **Exhibit "B"** to this Affidavit, used an IFR estimate of 1.2% to project 280,000 deaths from Covid-19 in Canada. In my opinion, a more reasonable estimate of IFR in Canada at that time was at least four times lower and since two-thirds of our deaths occurred in Long Term Care the IFR for people living in the general community was much lower again - probably in the range of 0.1-0.2% (one death in a thousand to one in five hundred people infected. Immunization of vulnerable people has probably pushed Canada's IFR well below 0.1%.

12. A mathematical model is only a hypothesis. To qualify as a scientific hypothesis, an hypothesis must make testable predictions. To be relied upon for public policy, a model must demonstrate that it can make accurate predictions.

13. The models used for Covid-19 do not make testable predictions. They produce a range of values that is so broad they cannot be disproven. This is not scientific.

14. Typically, public health has been directed by the worst-case predictions of the models. These worst-case predictions are consistently wrong and often wildly wrong. This is true not only for Ontario but also for jurisdictions such as Sweden, Brazil and Florida that have used much less restrictive measures. Mathematical models for other infectious diseases have a track record of wildly wrong predictions - SARS, H5N1 (bird flu) and H1N1 influenza are examples. Models that have not proven themselves reliable should not determine public health policy.

15. These lockdown measures had never been employed before on this scale and duration, anywhere, ever. They were not envisioned by our plans for pandemic influenza that our governments and public health had spent years developing. Pandemic influenza plans should have been the template for our response to Covid-19 because Covid-19 is very similar in its disease dynamics to a severe

influenza pandemic. Instead, these carefully crafted plans were abandoned in the blink of an eye.

16. Canada's plan for pandemic influenza embraces two overarching principles. First, to minimize the impact of death and illness, not just death and illness from the pandemic infection. Second, to minimize the disruption of normal life.[5] Attached hereto and marked as **Exhibit "C"** to this Affidavit is a copy of the Canadian Influenza Pandemic Preparedness: Planning Guidance for the Health Sector report, dated August 2018.

17. Ontario specifically endorsed these principles in the Ontario Plan for an Influenza Pandemic, March 2013 (p. 10).[6] The 4th chapter of the plan, pertaining to Public Health Measures, is attached hereto and marked as **Exhibit "D"** to this Affidavit.

18. Ontario's response to Covid-19 abandoned both of these principles. The focus has been almost exclusively on the pandemic infection Covid-19, virtually ignoring all other causes of illness, disability and death. The disruption of society has been profound and, unlike with pandemic influenza where any disruptions were expected to last a few weeks, with Covid-19 these disruptions have lasted interminably - now well over a year and with no end in sight.

19. The World Health Organization identified several potential interventions that were "not recommended in any circumstance", including contact tracing, quarantine, entry and exit screening and border closure.[7] Notwithstanding the parallels between the Covid-19 pandemic and an influenza pandemic, and the lack of any new evidence, Canada and Ontario adopted precisely these measures in their panicked reaction.

20. Lockdown measures were not based on strong science. Nor has there been any serious effort by governments to the evaluate the effectiveness of the different components of lockdown. Worst of all, we entered into lockdown without any clear goals and objectives. As a result, lockdown in various forms has continued for more than a year causing great harm[8] and dubious benefit.[9,10]

21. The harms from lockdowns are real and substantial - harms to education, to employment, to business, to arts and culture, to social interactions and to quality of life.

22. A recent report from Statistics Canada[11] confirms that the period of lockdown corresponds to a substantial increase in non-Covid deaths. While the number of these deaths is only about 15% of the number of Covid deaths during the same period, the non-Covid deaths are predominantly in younger people suggesting that the impact on years of life lost, a valid and important epidemiological measure, may be similar to deaths caused by Covid. Furthermore, we can expect the mortality impact of lockdown to stretch on for many years to come. Lockdown has scarred a generation.

23. Covid-19 has proven to be a serious public health problem. There have already been close to three million reported deaths worldwide and it is likely that more than a one billion people have already been infected - perhaps closer to two billion. However, to understand the public health significance of these numbers they need to be put in some context. Since about 60 million people die every year,[12] three million deaths represents about 3% (one in thirty) of global deaths over 17 months. Covid-19 deaths have been disproportionately among the frail elderly, particularly among the institutionalized frail elderly. Therefore the impact on premature mortality - potential years of life lost - has been substantially less than 3%. For comparison, almost two million people - overwhelming children - will die this year and every year from diarrheal illness[13] making a much greater impact on premature mortality, this year and every year, than Covid-19.

24. Canada has had about 25,000 deaths attributed to Covid-19. About 300,000 people die every year in Canada from all causes - on average about 800 deaths every day. Deaths from Covid-19 represent about 7% (one in fifteen) of all deaths in Canada during this period and, because of the high average age and frailty of people dying from Covid-19, the impact on premature mortality is almost certainly less than this. Furthermore, since two-thirds of deaths from Covid-19 in Canada

have been in LTC residents, there have been about 7,000 deaths in people living in the community spread over two waves of the disease, i.e., about 3,500 Covid-19 community deaths per wave. This is comparable to the number of deaths we would expect in a typical annual wave of seasonal influenza. This means that, while Covid-19 is a significant public health problem, the risk it poses to the vast majority of Canadians is not out of keeping with other more familiar problems, such as influenza. Outside of LTC, for every person who had died from Covid-19 in Canada, about 40 people have died from something else.

25. Tobacco addiction accounts for an estimated 40,000 preventable deaths every year in Canada - about twice the number of deaths we have seen from Covid-19. Taking into account the relatively younger average age of people who die from the effects of tobacco, the impact of tobacco addiction on premature mortality is likely four to eight times greater than Covid-19 in the past year. Tobacco addiction has had this tragic impact every year for seventy years and there is no end in sight. Tobacco addiction dwarfs Covid-19 as a threat to public health.[14,15,16]

26. A global outbreak of a novel respiratory virus is not unique. There were similar outbreaks in 1957 (H2N2 “Asian Flu”) and 1968 (H3N2 “Hong Kong Flu”). The Asian Flu is estimated to have caused between one and four million deaths globally in its first wave alone.[17] Asian Flu then returned on a seasonal basis for ten years causing many more deaths. In 1957 the global population was one-third what it is now and the proportion over 65 was about one-half current. Adjusting for population differences, an outbreak of comparable severity in 2021 would be expected to kill 6 to 24 million people in its first year. Covid-19 has not come close to this.

27. Any interaction between two people carries a risk of transmitting Covid-19. Since people must interact for us to continue living, we must balance risk of Covid transmission with the costs of intervention.

27. Large, indoor public gatherings can pose a risk of Covid transmission. Virtually all jurisdictions have taken some measures to control these sorts of gatherings.

However, there is very little real evidence beyond anecdote to support this concern. Furthermore, the specific measures to limit the spread of Covid-19 in these settings - including the size of the permitted gatherings and the rules of procedure - are highly variable between jurisdictions. There are no established, evidence-based protocols. The devil is in the details.

28. It is wrong for Ontario to limit arbitrarily the size of all religious gatherings. Instead, public health should work constructively with religious congregations to find ways to allow religious services to continue to function at an acceptable risk. Examples could include determining attendance limits based on characteristics of the venue, social distancing, screening at entrance, masks, limited singing, improved ventilation and shorter services.

29. There have been case reports of clusters of Covid-19 transmission events traced to religious gatherings reported from various jurisdictions. However, to assess the level of risk it is important to compare these instances with documented spread to the total number of attendances at religious gatherings - undoubtedly many billions globally. Covid-19 can spread in religious gatherings, but the rate appears to be negligible, based on Public Health Ontario's own data.[18] Furthermore, in many of these anecdotal reports of Covid-19 spread at religious gatherings, there was clear evidence of practices such as over-crowding, choir singing or poor ventilation that contributed to the risk.

30. To estimate the risk of contracting Covid-19 by attending a religious service in Ontario it is necessary to have an estimate of the number of people infected at religious services (numerator) and the number of people attending (denominator). I don't have access to either of these pieces of data for Ontario. However, there is some useful data from Manitoba that can advise this estimate. Specifically, in an affidavit[19] in a similar legal proceeding, a government epidemiologist was only able to identify a single Covid-19 fatality linked to a religious service over the past year. I have no direct data for the denominator but if I assume that during this period on average 10% of Manitobans attended a religious service weekly, this would

represent about six million attendances over the past year. One death in six million attendances is a very low risk, roughly the equivalent to the risk of death from driving 40 miles. Even a risk an order of magnitude higher would not, in my opinion, be sufficient to justify the inflexible restrictions on religious gatherings. For some people, a tiny risk of death or serious illness from Covid-19 (or driving their car to church) is worth facing for the benefit of attending a religious service.

31. There are many plausible explanations for the low risk of Covid-19 death from attendance at a religious gathering, based on the Manitoba experience. It is not essential to untangle these possible explanations to change public health policy. The proof of the pudding is in the eating.

32. A properly managed religious gathering in Canada would carry only a very small risk of Covid-19 transmission. Public health should reasonably allow gatherings of this type. People attending should be advised about the potential risk and people at increased risk of serious complications from Covid-19, based on age or infirmity, should be advised not to attend, although the choice should be left up to the individual. The impact of these events on Covid-19 transmission should be monitored and further measures adjusted based on evidence.

33. There have been two major developments with regard to Covid-19 in the past four months - vaccines and “variants”.

34. Safe and effective vaccines became available starting in late 2020. Ontario, quite appropriately, initially focused on immunizing Long Term Care residents and staff and then on the elderly. Although our vaccine roll-out has been slower than some other jurisdictions, we are already seeing remarkable benefits. Individuals who have been immunized are almost entirely protected from serious illness or death from Covid-19 and are much less likely to transmit the virus.

35. The “variants” represent the natural evolution of Covid-19 in response to the reproductive pressure from population immunity. The “variants” are somewhat more infectious than the original Covid-19 virus. The more infectious a virus the

less effective any lockdown measures. Furthermore, the current “variants” are almost certainly just the beginning of the changes in Covid-19. It has already shown itself capable of evolving quickly and there is no reason to expect the process to stop. On the contrary, as population immunity from infection and immunization increases globally, the reproductive pressure on the virus will increase and we can expect the process of evolution to, if anything, speed up.

36. This puts us on a very slippery slope with regard to lockdown measures. If we persist with this strategy we will need to be more and more stringent measures with less and less impact. Lockdown is a path that takes us nowhere.

37. Perhaps the greatest error public health has made in managing Covid-19 is the use of fear as a tool of public policy. This is short-sighted, cynical, and counterproductive. The great majority of Canadians - those under age sixty and healthy people to an older age - face about the same risk of dying from Covid-19 as they would from influenza.

38. The fear generated by public health messaging makes religion even more important to the health of believers. Promoting fear and then denying people their means of dealing with fear compounds the harm.

39. The science about many important aspects of Covid-19 is still uncertain. The non-pharmaceutical interventions that collectively constitute lockdown are not based on high-quality scientific evidence. Public health authorities have been required to make decisions to deal with a crisis in the context of scientific uncertainty. These decisions are of necessity based on judgement as much as science. Fair enough. However, when public health takes actions that are not based on strong science these actions need to be nuanced, flexible, balanced and constantly under review.

40. Ontario has applied a different standard for liquor stores than for other retail stores. It should use the same nuanced approach for religious services. There is no strong evidence that an arbitrary limit on the size of religious gatherings is an important element of Covid-19 control. There is no strong evidence that larger religious

based on strong science these actions need to be nuanced, flexible, balanced and constantly under review.

40. Ontario has applied a different standard for liquor stores than for other retail stores. It should use the same nuanced approach for religious services. There is no strong evidence that an arbitrary limit on the size of religious gatherings is an important element of Covid-19 control. There is no strong evidence that larger religious gatherings cannot be held at an acceptable risk, particularly with the full cooperation of the religious group. The harms from the arbitrary limits on the size of religious gatherings are obvious and substantial.

41. I make this affidavit *bona fide*.

1982 Master's in Health Sciences,
University of Toronto

1982 Fellowship in the Royal College of Physicians and Surgeons of Canada in Internal Medicine

1976 Medical Doctor (with Honours)
University of Toronto

1970 General Certificate of Education (Advanced) in History, English Literature and Geography,
University of London Board,
London, England

Academic Appointments:

2007-2016 Associate Professor
Faculty of Medicine
Queen's University

1996-2009 Associate Professor,
Department of Public Health Sciences,
Faculty of Medicine,

University of Toronto

1994-2000 Adjunct Associate Professor,
Department of Health Studies and Gerontology,
University of Waterloo

1987-1996 Assistant Professor,
Department of Biostatistics and Preventive Medicine,
Faculty of Medicine,
University of Toronto

1983-1987 Lecturer,
Department of Biostatistics and Preventive Medicine,
Faculty of Medicine,
University of Toronto

Previous Appointments (Selected List):

2003-2005 Infection Control Committee
York Central Hospital (Chair)

2001-2002 Health Policy Sub-committee
BIOTECanada

1998-1999 Ontario Expert Panel on Colorectal Cancer Screening (vice Chair)

1998-1999 Expert Panel on Cancer Epidemiology in Cape Breton (Chair)
Cancer Care Nova Scotia

1998-1999 Ontario Tobacco Strategy Expert Panel

1998 Expert Panel on Hepatitis C Epidemiology (Chair)
Health Canada

1998 Multidisciplinary Assessment Committee for New Opportunities
Canadian Foundation for Innovation

1997-1998 Steering Committee (Chair)
Canadian Consensus Conference on a National Immunization Records System
Health Canada

1987-1998	Advisory Committee on Communicable Diseases (Chair) Ontario Ministry of Health
1987-1998	Residency Committee, Community Medicine Program, Faculty of Medicine, University of Toronto
1987-1998	Federal/Provincial Advisory Committee on Occupational and Environmental Health
1993-1998	Editorial Board, "Health News", University of Toronto
1996-1997	Federal/Provincial/Territorial Implementation Team National Blood Agency
1996-1997	Board of Directors Canadian Blood Agency
1994-1997	Children At Risk Advisory Committee, Laidlaw Foundation
1996	Federal/Provincial/Territorial Working Group on Blood Governance (Co-chair)
1994-1996	Provincial (Ontario) Cancer Network
1994-1997	Advisory Committee, Centre for Health Economics and Policy Analysis, McMaster University
1994	Task Force on the Primary Prevention of Cancer (Miller Report)
1992-1994	Expert Advisory Committee National Population Health Survey
1988-1992	Federal/Provincial Advisory Committee on Community Health (Chair, 1992)
1990-1992	National Health Information Council

1990	Canadian Delegation, World Health Assembly, Geneva, Switzerland
198619-92	Public Health Committee Ontario Medical Association
1987-1991	Provincial (Ontario) Advisory Committee on AIDS
1987-1988	Expert Advisory Committee on Immunization, College of Physicians and Surgeons of Ontario
1983-1987	Health Protection and Promotion Committee, Metropolitan Toronto District Health Council
1985-1987	Emergency Services Committee, Metropolitan Toronto District Health Council
1986-1987	Working Group on AIDS Services, (Chair) Metropolitan Toronto District Health Council,
1985-1987	Executive Committee, Association of Local Official Health Agencies

Consultation Contracts for Schabas Associates Inc.(Selected List)

Biochem Pharma: Adviser on influenza vaccine issues

Cameco Corporation: Adviser on epidemiology

Canadian Blood Agency: Observer, GAT Task Force, June 25, 1998, Washington D.C.

Canadian Cancer Society: Cancer Control in Canada: Strategic Priorities for the Next Decade

Capital Health Authority (Edmonton, Alberta): Strengthening Population Health

Health Canada:

Biotechnology Surveillance, Centre for Surveillance Coordination
Health Protection Branch Surveillance Project

Setting Priorities in Public Health

Canadian Consensus Conference on a National Immunization Records System

Expert Panel on Hepatitis C Epidemiology

Expert Opinion of Canadian Red Cross Society Frozen Blood Samples

Laboratory Centre for Disease Control Business Plan Development (with HDP Consultants)

Evaluation of the Canadian Health Network

Surveillance Transition: Principles of Data Collection

Ontario Ministry of Health:

Ministerial adviser on blood issues

Primary Care Reform

Aventis Pasteur Ltd: Advisor on vaccine issues

Hospital Appointments:

2005-	Campbellford Memorial Hospital Campbellford, Ontario
2002-2005	York Central Hospital Richmond Hill, Ontario
1981-1999	Orthopaedic and Arthritic Hospital, Toronto, Ontario
1983-1987	Toronto East General and Orthopaedic Hospital, Toronto, Ontario
1977-1978	Parry Sound District General Hospital, Parry Sound, Ontario
1977-1978	St. Joseph's Hospital, Parry Sound, Ontario

Professional Training:

1981-1983	Senior Resident in Community Medicine, University of Toronto
1980-1981	Senior Resident in Internal Medicine, Wellesley Hospital, Toronto, Ontario
1979-1980	Junior Resident in Internal Medicine, Toronto General Hospital, Toronto, Ontario
1978-1979	Junior Resident in Internal Medicine, Women's College Hospital, Toronto, Ontario
1976-1977	Rotating Intern, St. Joseph's Hospital, Toronto, Ontario

Public Reports as Chief Medical Officer of Health:

1996: Tobacco - sounding the alarm
increasing smoking rates in Ontario teenagers, attributable to tax cuts and cigarette promotion are a public health crisis - this report recommends wide-ranging action to curtail this problem

1995: Immunization - the next steps
a review of the successes in immunization and a strategic plan for expansion of Ontario's immunization program, with a second dose measles catchup, a hepatitis B high school catchup and introduction of a pneumococcal program

1994: Opportunities for Health - progress against cancer

a description of the epidemiology and etiologies of cancer - a discussion of strategies for cancer control - a strong emphasis for promotion of non-smoking and healthy eating as our best means of controlling cancer - over 100,000 copies distributed

1993: Opportunities for Health - promoting heart health
a description of the underlying determinants of ischemic heart disease - smoking, blood cholesterol, blood pressure, body weight and physical activity - their distribution in Ontario and strategies for promoting heart health - over 100,000 copies distributed

1992: Opportunities for Health - a report on youth
an analysis of the main health challenges facing year old in Ontario with wide-ranging policy recommendations in areas of tobacco control, alcohol abuse, fitness, nutrition, pregnancy planning, control of sexually transmitted diseases, motor vehicle crashes and mental health promotion

1991: Tobacco and Your Health
a descriptive review of the patterns of tobacco use in Ontario and their health impacts over 200,000 copies distributed

Research:

HOUSE OF COMMONS
CHAMBRE DES COMMUNES
CANADA

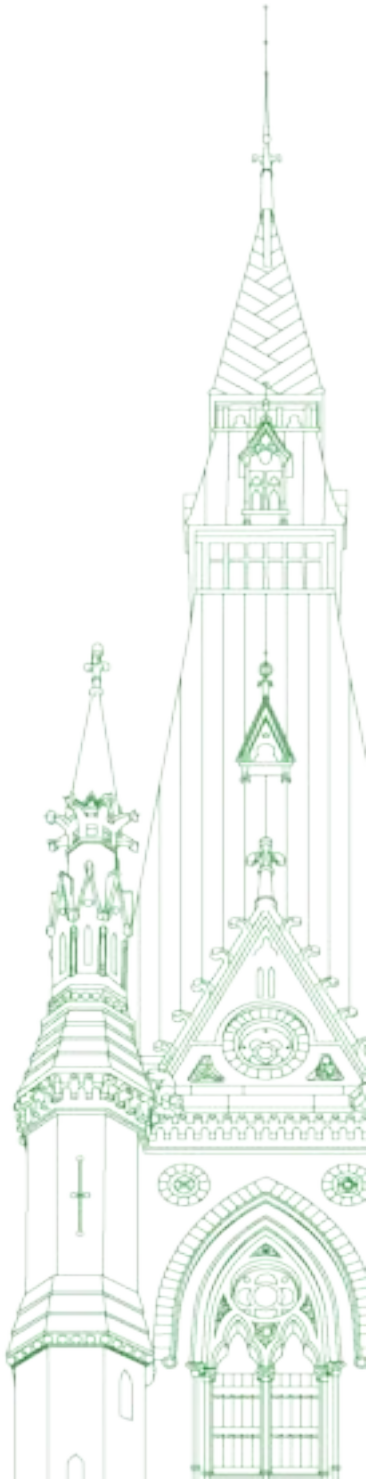
43rd PARLIAMENT, 1st SESSION

Standing Committee on Health

EVIDENCE

NUMBER 022

Wednesday, May 20, 2020



Chair: Mr. Ron McKinnon

Standing Committee on Health

Wednesday, May 20, 2020

● (1615)

[*English*]

The Chair (Mr. Ron McKinnon (Coquitlam—Port Coquitlam, Lib.)): I now call this meeting to order.

I'd like to welcome everyone to meeting number 22 of the House of Commons Standing Committee on Health. Pursuant to the orders of reference of April 11 and April 20, 2020, the committee is meeting for the purpose of receiving evidence concerning matters related to the government's response to the COVID-19 pandemic.

In order to facilitate the work of our interpreters and ensure an orderly meeting, I would like to outline a few rules to follow.

First, interpretation in this video conference will work very much like in a regular committee meeting. You have the choice at the bottom of your screen of floor, English or French. Please speak slowly and clearly and hold your microphone in front of your mouth.

If you will be speaking in both official languages, please ensure that the interpretation is listed as the language you will speak in before you start. For example, if you're going to speak in English, please switch to the English feed and then speak. This allows for better sound quality for interpretation.

Before speaking, please wait until I recognize you by name. For witnesses, the questioner will basically identify who they would like to respond to the questions. When you're ready to speak, click on the microphone icon to activate your mike. Should members need to request the floor outside of their designated time for questions, they should activate their mike and state that they have a point of order.

As a reminder, all comments by members and witnesses should be addressed through the chair. Should any technical challenges arise, please advise the chair or the clerk immediately and the technical team will work to resolve them. It may be necessary to suspend the meeting in such cases in order to sort things out.

Before we get started, could everyone check on the upper right-hand corner of their screen if they're using a personal computer. In the top right-hand corner there's a choice between speaker view and gallery view. Gallery view will ensure that all video participants can see each other.

I'd now like to welcome our witnesses. Each witness will have 10 minutes for an opening statement, followed by the usual rounds of questions from members. First, as an individual, we have Dr. Amir Attaran, professor, faculty of law, University of Ottawa. As an individual, we have Dr. David Fisman, professor of epidemiology, University of Toronto; and as an individual, Dr. Richard Schabas, former chief medical officer of health for Ontario. From BlueDot we have Dr. Kamran Khan, chief executive officer and founder; and from Dynacare we have Vito Ciciretto, president and chief executive officer.

Welcome everyone. Thank you for joining us today.

We will begin with Dr. Attaran. Welcome back. You have 10 minutes. Please go ahead.

Professor Amir Attaran (Professor, Faculty of Law, University of Ottawa, As an Individual): Thank you.

Good afternoon, ladies and gentlemen. Thank you for having me back at the health committee. I hope you've been well.

Mr. Tony Van Bynen (Newmarket—Aurora, Lib.): Mr. Chair, I'm sorry. The interpretation is overriding the English language.

The Chair: Dr. Attaran, are you on the appropriate translation channel? You should be on the channel for the language you're speaking.

Prof. Amir Attaran: I'm sorry, I forgot that. Let's start over.

The Chair: Thank you.

Prof. Amir Attaran: Good afternoon, ladies and gentlemen.

Thank you for having me back at the health committee. I hope you've been well and that your families have been keeping safe.

When we last met, Canada was in a full lockdown, and I strove to explain how we might get out of it. I offered a road map for exiting the lockdown gradually. That road map remains valid. First, a nationwide lockdown to bring disease transmission to virtually nil, and simultaneously a massive push to increase testing and contact tracing by a factor of ten or more, followed by a sequence of gradual reopenings and infection wavelets that are well calibrated by disease forecasts and monitored by testing to minimize deaths. No competent expert disagrees with this basic strategy.

I said that following this road map would be long and difficult, and I reassured you that there is light at the end of the tunnel. Sadly, some weeks on, today I am here to tell you that the light seems dimmer than I imagined, not for scientific reasons, but for political reasons, which you can fix.

As you know, countries like Australia, Denmark, New Zealand and Norway are executing successful reopenings. Meanwhile, Canada is flying somewhat blind because provincial and federal governments have still not solved their massive failure to co-operate in sharing and analyzing epidemiological data. Without data and analysis, many experts think reopening is arriving too early in some places like Toronto, which will kill people needlessly, and arriving too late in others, like Kingston or the Maritimes, after crippling the economy and ballooning the deficit. This isn't good.

My goal today is to offer a frank reality check, franker than Dr. Tam and Dr. Nemer delivered. I was saddened and frustrated that yesterday many of you asked excellent questions, but got evasive and, at times, mealy-mouthed answers. Please feel free to ask me those same questions. If I can help, I promise I will.

First, let's start with some data and the big question. Is Canada really bending the curve? The answer is sort of.

Many Canadians think we have done well because we are better than the United States, a country that has no public health care, vocal COVID-19 deniers and a president who recommends injecting bleach. The Americans are obviously not the right comparison for us. It's better to compare Canada with other wealthy countries, especially confederations, because they have federal-provincial complications like our own.

Please turn to the line graph I've provided to the committee. It's one of two graphs that were provided.

This graph shows confirmed COVID-19 cases, adjusted for population, starting on the day that a country exceeded the threshold of one case per million population. Canada was the last country to face COVID-19. That's luck, and it gave us extra time to prepare and the benefit of learning from others who went before us. With those advantages we achieved a lower infection peak. However, we come to the question of bending the curve down, we're doing poorly. Instead of the successful nosedive the graph shows for France, Germany, Spain or Switzerland, which they achieved despite a faster and higher peak than ours, our curve looks more like an undulating plateau that gradually drops off like a bunny ski hill. By May 18, our daily confirmed cases were tied with those on April 4. Between those dates are weeks of squandered time, lives and money, the latter being around $12 billion a week to the macro economy.

● (1620)

I find the comparison with Australia the most interesting. It proves that Canada could have done better. It is a large confederation of states, much like our own provinces, and it crossed the threshold of one case per million just one day before we did. In other words, we started off tied, but instead of dithering, Australia smacked down its curve hard and fast. Its results are almost as impressive as South Korea’s, which many reckon to be the world’s most successful country. Now Australia is opening thoroughly, and we are not, so the costs of this failure are just massive. The next time you hear the Prime Minister and Dr. Tam say that Canada is bending the curve, be skeptical. Be much more skeptical than you have been.

Let’s now talk about testing. You heard from nearly everyone that Canada is doing a poor job and that without more and faster testing it is impossible to reopen without unnecessarily risking and losing Canadian lives. The scientific goal is not simply testing the sick, but over-testing the vulnerable and anyone else who might have come been contact with the sick so as to isolate them for 14 days and nip outbreaks in the bud, yet Canada’s testing remains awful, especially in Ontario and Quebec.

The bar graph I furnished to the committee shows over-testing as the ratio of total COVID-19 tests per positive test. The higher that ratio, the better the chance of spotting infections and avoiding outbreaks. If one chooses not to worry about the price of testing—and one shouldn’t, because testing costs peanuts compared to hospitalizations or lockdowns—then it is far better to test too much than too little.

On this measure of testing, Canada lags behind not just top performers like Australia and South Korea, but also behind Ethiopia, Rwanda, Kenya, Cuba and Ghana. We are such testing tightwads that low-income countries in Africa surpass us. Africans also outclass Canada on contact tracing. Addis Ababa’s extensive testing and contact tracing puts Montreal and Toronto to shame.

For Canada to be beaten by the world's poorest countries has got to puncture the myth of competence and success. It cannot be that Canada lacks Africa's scientists, laboratories, equipment or chemicals, any of that. No. The reason we have failed is the cupidity and stupidity of certain governments, and this is where I put my constitutional lawyer hat on to talk about federalism. American lawyers have a great saying. They say that the Constitution is not a suicide pact, but I'm afraid, ladies and gentlemen, that during a killer pandemic our usually accepted federal-provincial relations can turn into a suicide pact.

I believe that our most fundamental failing right now is that pandemic responses are handicapped by a mythological, schismatic view of federalism. Thus, when provinces withhold epidemiological data or do a poor job of testing, collectively we grumble, we shrug and we mutter that health is provincial, but this is wrong. Speaking as a constitutional lawyer, health is actually a shared federal/provincial jurisdiction. The Supreme Court is dead clear about that. It says, "Health is a jurisdiction shared by both the provinces and the federal government." That's our Supreme Court, and it's perfectly accurate.

I think it is good for the federal government to let provinces run their show, and that's normally how it should work, but I'll suggest that a pandemic is not normal. There comes a point when the federal government must step in, the point where provincial actions are killing Canadians. If our country cannot show that once-in-a-century flexibility, then, yes, we are turning the Canadian Constitution into a suicide pact.

I know that what I've just said will be outrageously controversial. I'm sorry, but as a person who loves this country, I cannot let obvious mistakes pass and kill my neighbours.

● (1625)

Let me close with three recommendations.

First, Parliament must pressure cabinet into taking legal steps to force provinces to share epidemiological data. These are the data that scientists like Dr. Fisman and Dr. Khan absolutely need to keep me, you and your loved ones alive as this lockdown lifts. Parliament gave cabinet the power to demand data in section 15 of the Public Health Agency of Canada Act, but the Prime Minister has not used that power. It's frankly pathetic.

Second, demand that the Public Health Agency of Canada set minimum standards for things like testing. We cannot remain stuck behind Africa. Come on. It was only last week that the Prime Minister proposed a national testing strategy. That is much too late. We need it now.

The Chair: Dr. Attaran, you're at 11 minutes. Could you wrap up, please?

Prof. Amir Attaran: Sure.

Third, sign an accord with the provinces on co-operating throughout this pandemic. In Australia, the prime minister and the premiers signed a COVID accord on March 13, and the Vikings have killed this thing. Those Australian Vikings have put it down.

It's unbelievable that two months later, Canadian governments still have no COVID accord.

I'll close there. I hope you take these suggestions in the spirit they are intended, not to gore anyone's sacred cow, but to save the lives of the Canadians we love.

Thank you for hearing me.

● (1630)

The Chair: Thank you, Dr. Attaran.

We go now to Dr. Fisman.

Dr. Fisman, please go ahead. You have 10 minutes.

Dr. David Fisman (Professor of Epidemiology, University of Toronto, As an Individual): Honourable committee members, thank you for the privilege of appearing before you.

The last several months have offered us as a country extraordinary challenges. As an epidemiologist, internist and parent, these challenges have subsumed every part of my work life and my personal life. I haven't hugged my kids since mid-March. I have watched patients admitted to hospital with mild breathing difficulties and have seen these same patients wheeled into the intensive care unit 72 hours later. My colleagues have cared for married couples, and have had to tell the surviving spouse of the death of their partner while on clinical rounds. I've had the gratifying experience of watching our modelling work influence policy. I've also experienced the annoyance of watching epidemiological data abused, misused and distorted in support of various political, economic and social agendas.

The challenges I have faced pale next to those faced by many Canadians, those who have lost their jobs or lost their loved ones, often without the chance to hold hands or say goodbye. They pale next to the challenges faced by those who have worked at essential jobs under pressure from employers but without access to adequate personal protective equipment. We've watched extraordinary leadership from senior public health officials across the country. Here I'd like to single out the clear, compassionate messaging from Drs. Henry, Hinshaw and Tam for special praise.

We have also struggled with more limited leadership in other provinces. Here I would note in particular the failure of provincial public health officials in Ontario to act swiftly and courageously to stop the spread of COVID-19 in long-term care facilities, the failure to clearly articulate that COVID-19 was spreading in our communities in early March, and the failure to keep up with the best epidemiological evidence on important issues like transmission of disease by individuals with few or no symptoms.

So yes, we have seen many challenges, some of which we have met and some of which we have not. My group prepares forecasts for several federal and provincial colleagues each morning. We have documented a reproduction number for the epidemic in Canada of below one since around May 9, 2020. That's a hopeful sign. The reproduction number of an epidemic, the number of new cases created by an old case, is an index of epidemic growth and decline. A sustained reproduction number of below one suggests that this first wave of the COVID-19 pandemic is approaching an end in Canada.

I have been concerned by how this encouraging turn of events has been interpreted by some to mean that this wave is ending in spite of, rather than because of, the patient and selfless actions of many Canadians who've experienced hardship, isolation and deprivation in order to distance themselves from workplaces, friends and family. In Canada we have seen health care systems stretched and challenged, but we have not witnessed the tragic overflow of intensive care units as has occurred in Wuhan, Lombardy, New York and Madrid.

Make no mistake, our failure to experience these tragedies does not mean that models were wrong. Cities around the world that failed to react to approaching epidemics as promptly as Canadian cities did have experienced astounding surges in mortality—a 300% increase in deaths in New York, 75% in Stockholm, 460% in Bergamo, and a 100% increase in mortality in London. We reacted to approaching disaster in time to avert the worst of this first wave, but in our two largest cities, Montreal and Toronto, we still have several hundred individuals in intensive care units.

Now we face what I'll refer to as the “paradox of prevention”. By preventing widespread infection in the country, we've maintained susceptibility in the population, which leaves us vulnerable to future epidemic waves. This is the defining paradox of public health. Our fundamental deliverable is the non-occurrence of events. Those of us who work in the field are accustomed to having our outputs taken for granted. To note one familiar example, vaccination programs are criticized because their very success means we don't experience outbreaks. Perhaps a silver lining to this episode, moving forward, will be a greater appreciation of what public health provides us in normal times.

To go back to our successful avoidance of even greater tragedy in Canada in March and April, having achieved this important success, we need to move forward with economic revitalization. I think the presentation of our choice as economic revitalization versus prevention of disease transmission is a Hobson's choice or false dichotomy. We can't ignore our economy, but we won't have robust revitalization without strong surveillance systems and health protection measures. A frightened and grieving population will not drive a strong economy. In the United States, data assembled by JP-Morgan Chase show clearly that declines in spending are strongly linked to levels of disease activity.

● (1635)

The bedrock on which revitalization rests will be public health surveillance and laboratory testing. We can't see this epidemic without testing, and we can't fight an epidemic that we cannot see.

The virus is a slippery foe, and it's a study in contradictions. I call it Schrödinger's coronavirus. It's dangerous and it's lethal, but it causes mild illness and even infection without symptoms. It kills over 7% of the Canadians with recognized infection, but it gives most children a free pass.

Asymptomatic and presymptomatic infections are a Trojan horse that gives entry to congregate settings like long-term care and retirement homes, health care facilities, prisons and food processing plants. Once it's spreading in these institutions, it can take a terrible toll, as we have seen in long-term care facilities.

We can look around the world for successful responses to this epidemic and emulate best practices, but we can also emulate best practices here in our own country. Colleagues in Newfoundland have controlled COVID-19 rapidly; they tell us to hunt the virus and be proactive. Colleagues in British Columbia teach us how important clear strategy and communication are in this fight. Alberta can show us how to scale up testing, and our northern territories can show us how to protect isolated remote communities. Saskatchewan has shown us how to deal swiftly with growing outbreaks to prevent geographic spread of infection.

But I do believe that our most potent weapon in the fight is testing. Work by my colleague, Dr. Ashleigh Tuite, shows that without aggressive testing, control measures like contact tracing are likely to be fruitless, as we will only perform contact tracing on tested cases. If we fail to test at scale, we will miss too many additional cases for contact tracing to change the dynamics of the epidemic. It will simply be a waste of resources. If we test at scale, we can keep the epidemic in our sight and move toward economic revitalization while keeping Canadians safe.

Testing will be our eyes and ears as we move forward to open our economy, but the laboratory is a tool that needs to be used differently in different settings. We need to establish regular testing regimens for those who work in congregate settings with vulnerable individuals, especially in long-term care and in hospitals. Testing in a stable and consistent way allows us to estimate the reproduction number of the epidemic and know when we're headed back into exponential growth. We want to find all the cases we can. That's how we prevent sparks from turning into forest fires.

Hospitalizations and deaths are easy to see, but they're lagging indicators. Instituting control policies once those are surging means that we've already missed the boat. We can use non-traditional surveillance tools, too, like web-based syndromic surveillance, and even surveillance of sewage for coronavirus levels, as is already being done in other countries. Situational awareness will keep us safe as our economy comes back to life.

We can also demand more of our country. This epidemic shows us that having laboratories with 21st century diagnostic technology, but public health information systems that depend on fax machines from 1995, will hold us back. We can demand more transparency from our leaders. As action by the public is central to disease control, it's important that the public be kept in the loop and made to feel like they're on the team. Indeed, they are the team.

We need clear, transparent benchmarks across the country on testing, on turnaround times for case reporting and contact tracing and for the reproduction numbers that will be used to determine when we need to strengthen distancing and when we can loosen it. We will have more setbacks; the countries with the strongest response programs in the world have all suffered them. We will too. I'd ask you not to throw your hands up and let the virus win.

Don't let uncertainty distract you from the mission. Uncertainty is to be expected for a disease that's been in humans for 24 weeks. Don't let smug professors bully you about the absence of randomized controlled trial evidence for control of a disease that has only existed for half a year. We can acknowledge uncertainty and be humble about this disease, but always put the lives and livelihoods of Canadians at the forefront when we make our decisions.

Thank you for the opportunity to answer your questions today.

● (1640)

The Chair: Thank you, Dr. Fisman.

We go now to Dr. Schabas.

Please go ahead. You have 10 minutes.

Dr. Richard Schabas (Former Chief Medical Officer of Health for Ontario, As an Individual): Mr. Chair and members of the committee, it's a privilege to speak with you today.

I'm a retired physician. I practised medicine for 40 years in two specialties: public health and internal medicine. I worked in local public health for 15 years. I was Ontario's chief medical officer of health for 10 years. I was directly involved in the 2003 SARS outbreak as the chief of staff of York Central Hospital. I have published academic and popular articles on relevant subjects, such as SARS, quarantine and bird flu.

Canadians on the whole enjoy a wonderful standard of health, resting on the foundation of the social determinants of health: education, employment and our social fabric. Anything that threatens these foundations threatens our public health.

Canada is now faced with both a tragedy and a crisis. The tragedy is caused by COVID, a respiratory virus. It has the potential to cause the deaths of tens of thousands of Canadians, overwhelmingly old and infirm.

The crisis is caused by our attempts to control that virus. The crisis has the potential to cause severe and lasting damage to the fabric of our country's economy, education, social and cultural institutions, and mental health that will have repercussions for our public health for decades.

The tragedy is a natural disaster that saddens me and saddens us all. The crisis is a self-inflicted wound that frankly terrifies me. It offends social justice, because the burden of the crisis falls disproportionately on children, young families and blue-collar workers. The more we focus exclusively on COVID, the greater the danger to our public health.

The best analogy to the COVID outbreak is the H2N2 Asian flu pandemic that swept around the world in the fall of 1957. Asian flu caused more disease and a much higher death rate, especially in younger people, than COVID. Asian flu killed between one million and two million people in a matter of a few months in a world population one-third the size of today's. That's the equivalent of three million to six million deaths today, many more than from COVID. Asian flu was a tragedy, but it wasn't a crisis, because 60 years ago people responded differently. Some modest control measures were taken, but they were very temporary. The world moved on.

Perspective isn't very popular with COVID, but I think it's important. We get spooked by COVID deaths because every day we see the numbers for COVID, but not for anything else. Death is a common phenomenon in our world. Almost 300,000 Canadians will die this year, like every year, from cancer, heart disease, stroke, motor vehicle crashes, suicide and a myriad of other causes. Since mid-March, for every Canadian outside long-term care who has died of COVID, 50 Canadians have died of something else.

We have frightened people. Predictably, the media has led the way. But public health has also frightened people, I think, to promote better compliance with social distancing. This was wrong for two reasons: first, it's cynical; and second, it now will make it that much harder to step down.

My wife and I live in Toronto. When we walk our dog, we see two kinds of people— those like us who have done the math and aren't really frightened by COVID, and those who think walking the streets is dangerous. But there's a third group, the people in our building whom we haven't seen for two months who are too terrified to even go outside. Getting them to re-enter the world will be a tremendous challenge.

The only reliable defence against a respiratory virus is immunity. You can get immunity from being infected or you can get it from a vaccine. A safe and effective vaccine would be wonderful, but it would be foolish to build public policy around expectations of a vaccine any time soon. Any strategy that doesn't take us towards immunity ultimately leads us nowhere. So long as the disease is circulating elsewhere, it's coming back here too. Provincial or national elimination is a false promise.

● (1645)

Population immunity leading to herd immunity is a natural phenomenon not an intervention, not an experiment. Herd immunity is what has controlled every other respiratory virus. We will get there sooner or later with COVID. The policy challenge is to mitigate the worst effects of the disease while protecting the real determinants of our health: education, employment and our social fabric.

We have better information about COVID than we did two months ago. We know that COVID is very serious, certainly much more serious than I, for one, expected. However, it's also not the apocalypse that some of the models had predicted, not even remotely close. The comparison should be with 1957, not 1918.

We know that our health care system can cope. A combination of expanded capacity, better treatment strategies, and triage mean that the apparent capacity crisis in Italy has not been repeated here or really anywhere else. We know that the great majority of people in Canada are at very little personal risk of death from COVID. For virtually everyone under the age of 60 and for people without serious comorbidities to a much older age, the risk of death from COVID infection is not materially different from the risk of dying from influenza. We are two populations: the frail elderly for whom COVID is a deadly disease and the great majority for whom it is not.

Canada's experience in the last two months has been problematic. We seem to have been reasonably effective at reducing infection in the community, but we have not been effective in protecting the institutionalized, frail elderly because of a massive failure of infection control in some facilities. As a consequence, we have had many deaths, but we have relatively little population immunity.

The COVID outbreak in the northern hemisphere has been on the wane since late March—for almost two months. The policy tide worldwide is now towards reopening. Canada will be swept along.

My real concern is that the virus will return, probably in September, and that our attempts to control it with widespread testing and contact tracing will probably fail. I've worked long enough in public health to understand the limitations of contact tracing as a disease control strategy, particularly for a disease like COVID.

However, when this strategy fails, will we panic and lockdown again, this time indefinitely, or will we respond in a more measured and rational way? We have some time to prepare. If plan A is based on testing and contact tracing, we need a plan B. What should we do now?

First, we need to identify those things that are fundamentally non-negotiable. Education, which requires the reopening of schools, and employment, which requires that many people return physically to work, should be top of the list, along with access to medical and dental care.

Second, we need to be clear that we are pursuing the policy of mitigation not elimination. With mitigation, we can tolerate an increase in cases when we open up now, and again when the disease resurges in the fall. We will regard community spread as inevitable and as a step towards population immunity.

Third, we need to do serious policy work to identify those aspects of social distancing that are effective, acceptable and sustainable. Canada's latest fad is for non-medical masks, based on the thinnest of evidence. Let's think carefully before we change ourselves into a society that hides its face in public.

Fourth, we must develop better strategies to protect the vulnerable, particularly better infection control in long-term care institutions. This alone will go a long way towards reducing mortality.

Fifth, we need to change our messaging to the public to better reflect their real risk of serious illness and death so that people will be willing to come out of isolation and resume normal life.

Sixth, we need to look for ways to develop public health policy nationally. We need a national, not a federal, public health agency that engages the provinces with the federal government as equal partners.

Thank you.

● (1650)

The Chair: Thank you, Dr. Schabas.

We'll go now to Dr. Khan from BlueDot. You have 10 minutes.

Dr. Kamran Khan (Professor of Medicine and Public Health, University of Toronto, Chief Executive Officer and Founder, BlueDot): Good afternoon, ladies and gentlemen, and thank you for inviting me to be a part of this important discussion today.

First let me introduce myself and tell you a bit about my background and its relevance to today's meeting. My name is Kamran Khan, and I'm a physician trained in internal medicine, infectious diseases, and preventive medicine and public health. I practise medicine and am an epidemiologist who has been studying outbreaks and emerging infectious diseases at St. Michael's Hospital in Toronto for the past 17 years. I'm a professor of medicine and public health at the University of Toronto and am the founder and CEO of a digital health company called BlueDot.

What has motivated me to dedicate my professional life as a clinician, an academic and an entrepreneur to the field of emerging infectious diseases? Twenty years ago, I began my training in infectious diseases and public health in New York when West Nile virus arrived in the city and began its westward march across the continent. Two years later, shortly after the terrorist attacks of September 11, 2001, anthrax was weaponized and dispersed through the U.S. postal system, reminding us that deadly outbreaks can arise from deliberate acts. After returning to my home in Toronto two years later, a coronavirus known as SARS spread from mainland China to dozens of cities and countries around the world, including Toronto, where it triggered a deadly outbreak that lasted four very long months. While the world had never seen an outbreak quite like SARS before, it was clear that this wouldn't be the last time.

The world is changing in ways that are driving the emergence and spread of dangerous diseases, but it's also changing in other ways that can play to our advantage. The rise of big data, the advent of artificial intelligence and emerging digital technologies offer us the raw materials needed to literally spread knowledge around the world faster than any outbreak. This was the inspiration for BlueDot's founding six and a half years ago, to build a digital global early warning system for infectious diseases that can transform how the world prepares for and responds to tomorrow's inevitable infectious disease threats, whether they arise from Mother Nature, accidents or deliberate acts.

The early warning system we have developed at BlueDot serves three key objectives: first, to detect infectious disease threats as early as possible to buy ourselves valuable time; second, to assess their potential for global spread and impact so that we can channel our finite resources to the right place at the right moment; third, to empower a wider array of decision-makers, from government to health care to the private sector, with timely insights so that together we can mobilize highly effective, efficient and coordinated responses.

To detect threats at their earliest stages, our early warning system processes vast amounts of online data in 65 languages, searching for early signals of outbreaks involving over 150 different diseases and syndromes, 24 hours a day, 365 days a year. The surveillance engine does not rely solely on official news of outbreaks reported by government agencies, but also analyzes unofficial information generated through digital media, health blogs and other online sources.

This engine picked up an article in Chinese on the morning of December 31, 2019, reporting on an outbreak of pneumonia of an unknown cause in Wuhan, China. This event certainly captured my attention, given the number of parallels to the emergence of SARS in 2003. Within a few seconds of detecting the outbreak in Wuhan, our system analyzed the flight schedules and anonymous itineraries of hundreds of thousands of travellers departing Wuhan on commercial flights for destinations around the world. Given our early concerns about this outbreak, my team submitted results of this analysis for publication in an open access, peer-reviewed scientific journal on January 8, 2020, in order to make this data freely available for anyone to access. This analysis accurately identified many of the cities outside of mainland China that were among the first to confirm cases of COVID-19.

As cases of COVID-19 arrived in North America, our team began generating insights to support public health efforts to mitigate domestic transmission of this virus within our communities. These analyses made use of anonymous location data generated from mobile apps to understand the movements of populations—critical insights for public health officials to optimize and strategically make use of their finite human resources across the country and over time.

It's worth noting that BlueDot only makes use of third party data that is anonymized, adheres to all legal and regulatory requirements, and is aggregated up to the level of populations. These location data have been used for years in sectors from urban planning to transportation to retail, among others. Here, we're making use of them for the sole purpose of safeguarding communities and protecting lives during the midst of a pandemic.

● (1655)

At BlueDot, our diverse team, comprising physicians, veterinarians, epidemiologists, geographers, ecologists, data scientists and engineers, has been diligently working for the past six and a half years leveraging data, advanced analytics and emerging digital technologies to develop innovative solutions that are capable of generating insights to mitigate risks from infectious disease threats in our rapidly changing world. But insights are only meaningful if they are translated into action, and that translation can only happen through partnerships.

In this regard, BlueDot has a long-standing partnership with Global Affairs Canada, going back to 2014, in which we have been building and implementing digital systems to manage infectious disease risks across the Association of Southeast Asian Nations. In 2019 we began a partnership with the Public Health Agency of Canada, channelling our efforts to mitigate domestic risks from global infectious diseases. Now, as the COVID-19 pandemic evolves into new phases, we continue to work together to mitigate its impacts across the country.

I'd like to conclude by saying that Mother Nature is sending us a message. A confluence of forces in our rapidly changing world—population growth, urbanization, the industrialization of agriculture, the disruption of wildlife ecosystems, climate change and increases in global population mobility—is accelerating the emergence and global spread of infectious diseases with unprecedented consequences. As global citizens, this is a reality we have to confront, or we risk finding ourselves in the same precarious position we are in today a few years down the road.

We have also learned that outbreaks move incredibly fast in our hyper-connected world. If we want to remain a step ahead, we are going to have to move even faster. Thankfully, we have what is needed to generate powerful insights: access to diverse and novel data, and human intelligence coupled with artificial intelligence to derive meaning from these complex data.

We need to translate insights into actions that reach across the whole of society. Governments empowered with timely insights will be better able to protect their citizens and economies from dangerous global infectious diseases. Hospitals and health care providers will be better able to protect themselves and the rest of us from these very same diseases. Businesses will be better able to protect the lives and livelihoods of their employees and customers. Creating an ecosystem to manage these risks together is not only possible, but, in my opinion, necessary.

A final thought to leave with you is that our most valuable resource is time, and it is a non-renewable resource. When we get through COVID-19—and we will—the question for all of us will be whether we will use every day of peacetime to prepare for the next inevitable threat with the same sense of urgency with which we are responding to COVID-19 today.

Thank you for the opportunity to share my thoughts with this committee.

The Chair: Thank you, Dr. Khan.

We go now to Mr. Ciciretto, president and chief executive officer of Dynacare.

Go ahead, please. You have 10 minutes.

Mr. Vito Ciciretto (President and Chief Executive Officer, Dynacare): Good afternoon. Thank you, Mr. Chair and members of the House of Commons Standing Committee on Health, for your invitation to this very important meeting. I hope that each of you and your families are healthy and well. It is a privilege to be with you today on behalf of Dynacare to discuss the Canadian response to the COVID-19 pandemic.

At Dynacare, we believe that life is precious. Our mission is to support the health of Canadians with commitment and care. That is why we do what we do. Our 2,900 Dynacare employees deliver the highest level of clinical and scientific testing to provide the necessary information that supports the diagnosis, treatment and well-being of Canadians. Each and every day we provide testing and medical laboratory services to over 32,000 Canadians across the country, amounting to over 11 million tests annually. We operate 200 convenient and accessible specimen collection centres in Ontario, Manitoba and Quebec. We operate seven state-of-the-art laboratories in four Canadian provinces. We report over 500 critical results requiring immediate action by physicians.

Our goal is to inspire confidence in Canadians when it comes to managing their health and well-being. To achieve this, we have elevated the patient experience at our specimen collection centres. We continuously innovate by introducing new and improved test methodologies such as genetic testing; liquid-based cytology; non-invasive prenatal testing; and the piloting of Pixel, a self-collection test methodology utilized in remote rural communities. We have introduced patient-friendly diagnostic testing reports and digital apps that help Canadians better manage their health journeys.

This unprecedented pandemic has highlighted that the work we do at Dynacare matters now more than ever. We are very proud to play a critically important role in supporting the provincial public health authorities of Ontario, Manitoba and Quebec in their efforts to control this pandemic. Since March 25, our talented scientific and laboratory professionals at Dynacare have conducted over 40,000 COVID-19 molecular tests across these provinces, including COVID-19 testing for members of vulnerable and priority populations, such as those in emergency shelter systems, residents of long-term care facilities, EMS first responders and health care workers.

Even throughout this pandemic, Dynacare has continued to operate its laboratories and accept patients at our collection sites for urgent non-COVID-19 testing. In addition to the provision of COVID-19 testing, our community laboratory infrastructure has helped to alleviate pressure on provincial public health systems and hospitals. In particular, our medical couriers have quickly and safely transported COVID-19 test specimens from screening and assessment centres to Dynacare, public health and hospital laboratories. On behalf of the provincial public health labs, we have delivered negative COVID-19 test results to over 25,000 patients. We have supported vulnerable populations by establishing designated Dynacare specimen collection sites for immunocompromised patients and for COVID-19 positive patients. We have engaged in non-COVID-19 sample collection at long-term care facilities.

Our employees have rallied behind Dynacare's response to this pandemic and, as such, we celebrate the many acts of compassion through our Dynacare health care heroes social media campaigns. Our people are the ones who have truly stepped up.

The COVID-19 testing system has generally been working well with strong collaboration among public health agencies, community laboratories and hospitals. But, as with any unprecedented and rapidly evolving environment, there are challenges and opportunities for improvement.

The technical nature of the nasopharyngeal collection process, along with the required swabs that are employed in the collection of a COVID-19 sample, have been rate-limiters in terms of testing and have increased the demand for PPE. At over 200 collections centres, Dynacare has over 850 phlebotomists who are not authorized to collect samples using the current collection devices.

● (1700)

By employing alternative specimen collection procedures used in other countries, our team can support provincial screening. To this end, Dynacare is embarking on a study with Sunnybrook Occupational Health to validate alternative sample collection methods using saliva and front-of-nose collected specimens. The results of this study are expected within a few weeks.

Second, shortages of testing reagents and collection kits were common early in this pandemic. Due to increased vendor production and the proactive response of our supply chain team, we appear to have sufficient supply for our current volume of testing. However, in order to support expanded testing needs, our intention is to increase testing capacity, both through new collection techniques and through supply chain preparedness. Global demand has made it very difficult to secure additional testing capacity and reagent supply on a timely basis. Vendor allocation practices drive more test capacity and reagent to jurisdictions that have been more severely impacted by the COVID-19 virus than Canada has.

It's important to everyone at Dynacare that at the end of every laboratory test we perform there is a person—a mom, a dad, a daughter, a friend. It is not uncommon for our dedicated teams of employees to go above and beyond the call of duty by helping to secure a replacement test requisition for a patient, by leading a drive-by convoy to acknowledge the efforts of front-line health care workers at hospitals, or by making extended efforts to contact a patient with a critical result.

We treasure the value that our dedicated employees bring to the health care system, and we go to great lengths to take care of them. Notwithstanding the significant drop in non-COVID-19 test volumes during this pandemic, we have not thus far implemented furloughs, layoffs or reductions in base pay, due to our long-term philosophy and government wage programs. We are very proud of this and believe that it positions us well for the future. As doctors' offices and clinics reopen, as elective surgeries start again, as insurers and employers resume regular activities, Dynacare will be in a position to meet the laboratory testing needs of our patients and clients and support our health systems across Canada.

Unquestionably, our workplace will be defined by a new normal, with new social distancing and PPE protocols that will protect our patients and our people. As the number of patients requiring service continues to increase, these new protocols will demand the need to adapt, and we will.

Across Canada, some provinces are slowly beginning to open back up in ways that we would not characterize as business as usual. In the absence of a vaccine and lack of scientific consensus on the potential for immunity to the COVID-19 virus, some employers are expressing concern that their workplaces could be prone to COVID-19 outbreaks. Employers across a number of sectors, including food and beverage production, natural resources, manufacturing and many more have expressed an interest in the provision of COVID-19 testing at their own cost. Dynacare's priority will always be supporting health systems in responding to the emergency presented by COVID-19. As the economy opens up, we see a need to work with industry to avoid workplace outbreaks as a means to limiting the community spread of COVID-19.

Key to restarting the Canadian economy is high-quality antibody testing, which can determine whether an individual has been exposed to the COVID-19 virus. Public health authorities, in conjunction with medical and scientific experts, are working to determine how COVID-19 antibody testing could be applied.

This past week, two COVID-19 antibody tests were approved by Health Canada. Dynacare is currently working with two additional vendors who will be seeking Health Canada approval for an antibody test. A community laboratory like Dynacare is very well positioned to support large-scale provincial COVID-19 antibody testing surveillance programs through its extensive specimen collection network of 200 centres, our well-equipped laboratory facilities and our extensive logistics network. We do this every day—efficiently, effectively and with compassion.

In public health emergencies, those in poor health or with underlying chronic conditions are often the most vulnerable.

● (1705)

For many, the COVID-19 pandemic has emphasized the importance of keeping Canadians healthy and decreasing the prevalence of chronic conditions such as cardiovascular disease, lung disease, metabolic syndrome and diabetes.

At Dynacare, we believe that life is precious, and we look forward to continuing to improve the health of Canadians by providing ongoing support to provincial health care systems and through health and well-being programs at Canadian workplaces both through the COVID-19 pandemic and beyond.

Thank you again for the opportunity to address this committee.

Take care and be well.

The Chair: Thank you, Mr. Ciciretto.

We'll start our rounds of questioning now. We will do three rounds. We will start the first round with Ms. Jansen.

Ms. Jansen, please go ahead. You have six minutes.

Mrs. Tamara Jansen (Cloverdale—Langley City, CPC): Thank you to everybody for all your presentations. That was very wholesome. It was great.

I'd like to start with Professor Attaran. I found your written submission very interesting, and I had to chuckle when you pointed out the fact that some hospitals are still faxing in their data. My first foray into state-of-the-art technology on the farm was when we bought a fax machine back in 1992, 28 years ago.

However, in order to stay in business, we obviously had to invest in better and better data collecting technology. I have to say that I was completely shocked to find out from previous witness testimony at this committee that our health care system doesn't have a real-time data collection system in place, especially considering the different recommendations that have been made following previous pandemics.

We have had several witnesses come to this committee and beg us to find a way to move forward with a pan-Canadian data collection system that works in real time. A system like this could help us on so many different levels, not just during a pandemic, but it seems there is this fear that sharing information in this way will compromise the autonomy of provincial and local health authorities.

In your opinion, is there not a way to ensure that each provincial and regional jurisdiction can continue to make decisions that make sense for them while still sharing their data and helping the country with a more informed pandemic response?

● (1710)

Prof. Amir Attaran: What a great question, thank you.

On the question of sharing epidemiological data, it's like this: If you had a number of people who had pieces of a map of a minefield, would you tolerate them not sharing that data? I think you'd probably want to have a map of the entire minefield, not just your little patch of it, if you were setting out on a journey.

The current situation is as foolish as that. Each province has a certain amount of data about the outbreak within its borders, and it can either contribute that piece to modelling exercises or not, and depending on whether it does so or not, we have a better or worse view of the epidemic.

The answer to your question lies in a legal part as well as an administrative part. Legally it's very simple. Cabinet just needs to use section 15 of the Public Health Agency of Canada Act and issue an order in council that data must be provided, period.

Parliament gave it that power. It simply leaves me speechless that the current cabinet hasn't used it. That is something I hope you follow up.

Mrs. Tamara Jansen: Okay, I have a really short amount of time, sorry.

Prof. Amir Attaran: I'm sorry.

Mrs. Tamara Jansen: Okay, I appreciate that.

You mentioned in your submission the dysfunction that we have in sharing data, and, again, being from a business background.... I worked in the retail sector for many years, and our spring season was always very short. We had an eight-week period across multiple provinces, so that meant timely data was absolutely critical to make these decisions on where to send what product and when. We were able to take into consideration those regional differences to ensure the right assets were sent to the right place at just the right time, and we know the technology is available for a pan-Canadian data system.

Yesterday Dr. Tam mentioned that PHAC has no choice, and now you are mentioning they actually do under section 15, so it strikes me that, if Statistics Canada is able to aggregate information about Canadians without violating privacy rights, surely the health care system can do the same.

Prof. Amir Attaran: Statistics Canada can do the same, too. They could build the system inside of about a couple of weeks, I'm told, but they need the mandate from cabinet. That is what's missing. There you go.

Mrs. Tamara Jansen: Okay.

Prof. Amir Attaran: I will just add one last thing to this. There was a time in this country when the federal government did provide a contract to somebody to develop such an epidemic data reporting system. It was given to IBM Canada. The system did not function, and they are the same ones who are behind Phoenix, so there is not a good history here.

Mrs. Tamara Jansen: Okay. Thank you.

I've asked numerous witnesses if they would give PHAC a grade on their pandemic response. So far no one has been willing to give me a straight answer. I've been hearing of some backlash by PHAC to those who are vocally critical in their response to the pandemic.

Are you willing to give me a grade, or could that disadvantage you in your work in some way?

Prof. Amir Attaran: My grade is a C-minus or a D. And there is retaliation, yes. Since the last time I appeared in front of this committee, and was negative about some of those efforts, I was asked to join a grant application with people from PHAC. I understand they said they wouldn't participate unless I stood off it, which I did willingly because I didn't want to cause trouble for my colleagues. But I don't feel there should be retaliation against witnesses simply for providing our democratic government what we think is the truth.

Mrs. Tamara Jansen: Okay. Thank you for that direct answer. I appreciate that.

Yesterday, Dr. Nemer talked about the task forces she set up to tackle the Canadian pandemic response. She mentioned that, although she could share the agendas, she couldn't share the deliberations or findings because they are secret. I believe other countries around the world that have set up similar task forces are sharing their research papers publicly, which helps us all.

Do you think the findings of these task forces should also be public so we can have that timely data sharing for a better pandemic response?

● (1715)

Prof. Amir Attaran: I can't even believe that's a question. Of course, it has to be public. Science is always conducted in public. If you look at a country like Switzerland, they too have a task force on COVID, a scientific task force. If you go to the website over two dozen public reports by that task force are published. If Switzerland, little Switzerland, can get two dozen reports out of their task force by now, why does Canada have zero? It's shameful.

The Chair: Thank you.

Mr. Fisher, please, go ahead. You have six minutes.

Mr. Darren Fisher (Dartmouth—Cole Harbour, Lib.): Thank you, Mr. Chair.

Dr. Fisman, you have a wealth of experience in the battle against infectious diseases, yet you've publicly explained that predictions you made earlier this year on the virus were wrong. I think we can both agree that hindsight is 20/20. There's been a lot of discussion at this committee about why certain decisions were made in the early days of this virus.

I wonder if you could explain to this committee, and to Canadians, about the difficulties of making predictions around a novel virus, and why what's considered the best advice one day can change and evolve so quickly the next?

Dr. David Fisman: I think part of the difficulty relates to the fact that viruses are the troublemakers, and Dr. Khan alluded to this. The troublemakers tend to be RNA viruses, that's their genetic material that comes from animals. RNA viruses are very good at mutating. What we see with this virus, which is a cousin of SARS 1, and bears a lot of similarity to SARS 1, is that it behaves differently in important ways. Being 80% similar can still translate into some very important differences, but some very important similarities.

What we tend to see, what we almost always see with infectious diseases as they emerge, is we find out about hot spots first. Typically we have this sense of the virus being more virulent than it ultimately turns out to be. That's certainly been the case with some outbreaks. What we saw with this virus, also initially, was it looked a lot like SARS based on the information we knew from China. I've acknowledged publicly I think my biggest mistake was thinking it really was looking like SARS in China. We did some forecasting on how the Chinese seemed to be doing in controlling it, and we accurately forecasted that it would be done in Wuhan by early March. That was right, but the difficulty was we didn't see Iran coming. Once you saw this in Iran, you knew the game was over, and this was going to disseminate around the world.

They're all the same, but they're all different. When you look at some of the key parameters, as we talk about, with these diseases, which let you sort of predict how things are going to play out, some important numbers include the reproduction number of the disease, the number of new cases per old case. This virus turns out to be a real trickster, in that it's got what's called an overdistributed reproduction number, where many cases are dead ends but some individual cases make 40 secondary cases. You see that play out again and again, whether it's in nursing homes, on cruise ships or in restaurants. As you know, there's the single individual in Korea who infected 40 secondary cases and sparked a massive outbreak in the city of Daegu.

That makes it difficult. It also provides a potential vulnerability for the virus in terms of control, because once you get rid of those large gatherings that make super-spreading events difficult, the virus becomes much less transmissible. The initial case fatality that we saw coming out of China—that's deaths per case—was listed as 2.4%. Of course, deaths go up slowly with this thing, because people die in the ICU. The China case fatality I think at this point is 5% or 6%. We're at 7% in Canada.

As for what we know now, we've been helped a lot in this regard by data from Spain from last week, from a national seroprevalence study, where they were able to find both the recognized and the unrecognized infections. About 5% of the country of Spain has had this, with 27,000 deaths. Now we're able to go from a case fatality in Spain, which is deaths per recognized case, down to an infection fatality rate, which in Spain we now are pretty sure is about 1.2%, based on seroprevalence data.

The fact that Spain is at 5% prevalence 30,000 deaths in, with an infection fatality rate of 1%, makes me very concerned about some of Dr. Schabas's remarks in terms of moving towards herd immunity. We think that we'd hit herd immunity at 60% to 70% of Canadians infected. Seventy per cent of Canadians infected is 28 million people, and 1% of that is 280,000 Canadians dead. I would note that the failure to have mass mortality in Canada to date relates to the public health response.

I would also note that we can do this because we've shown around the country that we can control this disease without just letting it rip and pushing for herd immunity, as they're doing in Sweden. We've seen competence in British Columbia. We've seen tremendous competence in Atlantic Canada and on the Prairies. We can do this. We just need to get the job done.

Throwing your hands up and saying that we're going to follow Stockholm, Sweden, which is currently leading Europe in per capita mortality, is not the way to go, in my opinion.

● (1720)

Mr. Darren Fisher: Thank you. I had other questions for you, and I think we've run out the clock—

Dr. David Fisman: I'm sorry.

Mr. Darren Fisher: —but I do want to say that this is excellent and very thoughtful testimony, and I want to thank you for that, Doctor.

Dr. David Fisman: Thank you.

Mr. Don Davies (Vancouver Kingsway, NDP): Mr. Chair, I have a point of order.

I'm still somewhat shocked at the evidence I heard from Dr. Attaran about him potentially being discriminated against or having retribution threatened against him as a result of this testimony before the health committee. All of us, as members of this committee, have an interest in upholding the integrity of this committee and ensuring that all witnesses who come before us can give us the sincere, unvarnished benefit of their opinion, particularly when we're talking about science.

I would like to ask that this committee formally request that Dr. Attaran indicate to us full details of what has occurred by PHAC or Stats Canada, or whoever it was, to ensure that the integrity of this committee is upheld at all times.

The Chair: Thank you, Mr. Davies.

Under our current operating mandate, we don't have the authority to do that. We can certainly invite him to submit all of the evidence, all of the allegations he has, to us or to the Speaker of the House. We would be unable to deal with a matter of this kind in our current operating situation.

Mr. Don Davies: Mr. Chair, if I might—

Mr. Robert Kitchen (Souris—Moose Mountain, CPC): Mr. Chair—

Mr. Don Davies: —I would vehemently dispute that. This committee is mandated to receive evidence. It's clearly in the consent order of the House of Commons. If we have evidence before us that witnesses are being pressured or intimidated against not giving evidence, that is a direct interference with the precise mandate of this committee.

On the record, I'm happy to ask Dr. Attaran to provide those details, but for the record, I want to state in the strongest terms possible that it is absolutely the prerogative and mandate of this committee to ensure that we uphold the integrity of our process. Any time we hear that a witness may have been intimidated, or harmed in any way, for simply accepting the invitation from us to come and give us the benefit of their testimony, it's absolutely part of the pith and substance of this committee, and I will pursue this matter fully once we get that information from Dr. Attaran.

The Chair: Thank you, Mr. Davies. Your point is well taken. I will take the matter under advisement and—

Mr. Robert Kitchen: Mr. Chair, I have a point of order.

The Chair: Dr. Kitchen, go ahead.

Mr. Robert Kitchen: Mr. Chair, I'm 100% behind what Mr. Davies said, but my point of order extends further than that. We as committee members are here to present and ask questions, to protect our witnesses as well as ourselves, and to make certain that we have that protection. If we do not have that as a committee, the questions and points that we may bring up can be held against us, and that's just not acceptable. How can we function as a committee if that's not the place?

● (1725)

Mr. Matt Jeneroux (Edmonton Riverbend, CPC): Mr. Chair, just to add on to that, if you could point us in some direction as to why you don't think we have these powers to be able to do that in this committee....

I disagree with you. I agree with Mr. Davies that it's within the mandate of this committee to ask for that testimony.

If you can point us in that direction, please do. If you can't, then I suggest we allow Mr. Davies to proceed with his point of order.

The Chair: Your points are well taken. It should be pointed out that all testimony before this committee, when it's operating in official capacity, is privileged. We have parliamentary privilege. Any repercussions that follow from that would be a serious matter, but our mandate is solely to receive evidence.

We are explicitly allowed to move motions relating to the invitation and scheduling of witnesses. We do not have the authority at this time to undertake a motion to demand information about matters such as this, but I certainly would welcome Dr. Attaran's information if he should provide it.

I wonder if our clerk would like to give an opinion on this.

[*Translation*]

Mr. Luc Thériault (Montcalm, BQ): Mr. Chair, I would like to raise a point of order.

Professor Attaran seems to want to add a comment. Perhaps he could clarify what it is, which could help you deliberate further. I would be prepared to let him speak quickly, since I thought I saw him raise his hand. So I would like us to hear what he has to say. Then you could deliberate on that.

[*English*]

The Chair: Witnesses aren't able to participate in the committee on points of order, but as I said, I will welcome his information. I invite him to bring it to the committee, to send it to the committee.

The clerk will be looking into this matter and will come back to us at a later time with an opinion. In the interim, I will reserve judgment and suggest that we carry on with the testimony.

Mr. Thériault, please go ahead. You have six minutes.

[*Translation*]

Mr. Luc Thériault: Thank you, Mr. Chair.

I am going to address Professor Attaran first. These days, we can say that science is being tossed around a lot. All decisions are supposedly made in the name of science. One might even think that it is being used more to justify some political dithering.

Mr. Attaran, on page 3 of your brief, you say the following:

> ...the Prime Minister hesitated, perhaps because of the scientifically inaccurate advice from his Minister of Health, that closing the borders to slow the disease down is “very ineffective.”

Some people argue that border closures have no significant effect in stopping the spread of the disease. I understand you disagree. Should the borders—especially the U.S. border—have been closed much sooner?

Did we have all the information we needed to make that decision? If not, what would have been required to make that decision as quickly as possible? What is the reason for the conflicting scientific advice?

Prof. Amir Attaran: You are right that scientific issues are often politicized, and that was the case with the border closure.

In my view, the purpose of closing the border is to protect us, especially in the case of the U.S. border. However, as you already know, the WHO says that it is almost useless, and the minister said that it is useless, but I disagree.

I know that, after the disaster we are now experiencing, we will rethink these issues. In Africa, for example, the borders between countries were quickly closed. They learned that lesson from the Ebola crisis. Now we see that nations are more protected. The infection rate in Kenya and Rwanda, for example, is lower than it would normally be. So it works.

● (1730)

Mr. Luc Thériault: Some witnesses have told us that we cannot fall behind in the case of this virus. The fact that the incubation period is often 14 days means that, since the beginning of the pandemic, we have constantly been feeling that we are playing catch-up. So I imagine that things should have been done differently and that decisions should have been made much more quickly.

You were talking about structural and systemic difficulties related to the Confederation and the inability of the scientific community and public health authorities to work in a coordinated manner and in real time with respect to sharing data.

What is the point of not working together? What justifies it? You gave the example of Ontario during the SARS episode. What is the point of those provinces or Quebec not working together? I have trouble understanding that.

Prof. Amir Attaran: I don't understand it either. It's almost dangerous to think of our Confederation as 10 provinces that are not connected through their biomedical resources, especially considering the virus that's connecting us right now. You are right.

Mr. Luc Thériault: How could legislating or establishing regulations be more effective? I'm trying to understand the motivation behind this inefficiency.

Prof. Amir Attaran: To answer more effectively, I have to speak in English. May I?

Mr. Luc Thériault: Yes, of course.

[*English*]

Prof. Amir Attaran: I'm sorry, but some of the legal words I don't know in French. I try.

The order in council that would be necessary to make data exchange mandatory between the federal government and the provinces is not a controversial thing. It is something that Parliament put into the law in, I believe, 2004 or 2005. Simply put, it should be used. We should not let our preconceptions about the appropriateness of what the province may do, or what the federal government may do, stand in the way of the clear reading of the law. You, as parliamentarians, created that law on sharing, and I'm grateful to you for doing so. It's a very useful tool, but it does need to be used.

I think Dr. Fisman would probably be able to add something to this.

Dr. David Fisman: I'm not sure, though I could add my perspective as a researcher based in Toronto since 2006.

What I've always found astounding is the failure to make accessible data that are paid for, assembled and cleaned on the public dime available to Canadians in a manner that doesn't threaten anyone's privacy or well-being. I've found that astounding for a long time.

A lot of my work, since I've come to Toronto, uses the national hospital discharge survey from the United States, which is pretty similar to the stuff you get from CIHI, except that if you ask for the data online from the CDC, they will FedEx it to you and pay for the FedEx, whereas if you ask for the same stuff from CIHI, you pay them. I don't understand it.

There's a much deeper issue here than COVID, and I thank my colleague for flagging it. We have a culture of what I call data hugging in Canada, and it does need to change. It harms us all.

● (1735)

The Chair: Thank you, Mr. Thériault.

We will now go to Mr. Davies.

Mr. Davies, please go ahead for six minutes.

Mr. Don Davies: Thank you.

Dr. Fisman, last week you were interviewed on TVO and you said, “I think there are a lot of folks who are itching to declare victory and open things up again, which is a bit of a problem because the reason that infections are subsiding is because we have distancing in place.” Are you concerned that some provinces and territories may be moving too rapidly to open?

Dr. David Fisman: I think my own province is, and I appreciate tremendously the pressure our premier is under. I think he's done a marvellous job given the cards he's been dealt, but I'm also aware there are a lot of folks who want to get back to business.

I'm not sure whether doing a screen share on Zoom is part of parliamentary committees, but we are looking at reproduction numbers here in Ontario. That is the number of new cases per old case. What we see is that the disease has clearly surged over the last week in Toronto, particularly in Peel. Part of that is from the liberalized use of testing, which drives the numbers up. Part of that is probably from the anticipation of greater economic opening. I think we may get a couple of rude bumps along the way, but ultimately distancing will be our parachute. If things start to look too grim, they'll be able to close things back down again, but, yes, I'm concerned that there's tremendous momentum to get folks back to business.

There's a lot of economic activity that could resume safely in the province of Ontario. Ontario is a big place. It's bigger than France, and we have regions.... Dr. Attaran referred to the city of Kingston. It has had one or two cases over the last 10 days but is subject to the same blanket lockdown as Toronto and Peel, which have had a couple of hundred cases a day. I think more—

Mr. Don Davies: I'd like to direct you to some of the things we should be doing.

You also said in the interview, “Predictably, as we reopen, we’ll see a resurgence of disease.”

Dr. David Fisman: Right.

Mr. Don Davies: That's exactly what we've seen in Korea and in Germany this week, two places that controlled their initial epidemic faster than we did and are moving toward revitalization. They've seen resurgences, just as Singapore did before them and just as Wuhan did last week.

What do you recommend we do, given that you see resurgences? What steps should we be taking to get in front of that, if there are any?

Dr. David Fisman: The resurgences will happen. It's just how this works. It's simple math. The reproduction of a disease is number of contacts times the probability of transmission per contact times how long a person is infectious for. We can forget about immunity right now, because immunity is low. Even if it's 5%, it's too low to bring the reproduction number down. Therefore, as contacts go up, the reproduction number predictably goes up.

The Chair: Doctor, could you please hold the mike?

Dr. David Fisman: My apologies.

We're going to go too far. We're going to try to open things up and go too far. That's why we need strong surveillance systems, to see that as it happens.

Mr. Don Davies: I want to move to testing. Maybe you and Dr. Attaran can comment on this.

We hear repeatedly at this committee, from every expert, that we have to test, test, test, and that it's key to getting control of this disease and reopening. However, we've barely done a million tests since January. Wuhan is gearing up to do a million tests per day. We're behind Germany. We're behind South Korea. In fact, we're at barely half of Dr. Tam's target of 60,000 tests a day.

Why are we unable to test at the rate that all experts are telling us we need to? Where is the problem here?

Dr. David Fisman: I don't know. Mr. Ciciretto is an expert on how labs work and could probably give you a more meaningful answer than I could.

We do work with local public health units. My concern at the moment is that it's not just the testing. If people are saying we're going to do contact tracing once we open up and we're going to track the contacts of cases as they did in Korea—I think they had a couple of hundred secondary cases associated with a nightclub outbreak—I don't think we could do that.

We have lags all the way along and it gets back to the 1990s technology where it takes time to test, the tests get faxed, it takes a while for them to percolate through the public health system and—

● (1740)

Mr. Don Davies: I'm sorry to interrupt, but I want to give Dr. Attaran a chance to weigh in on this too.

Other countries are testing at much higher rates. Why can't Canada do it?

Prof. Amir Attaran: Again, I am not a testing expert. What I can say is that it's obviously a systemic and administrative problem, because for Ethiopia or Rwanda to be surpassing us in testing.... They're getting the reagents and supplies from somewhere. They are pulling it off.

I did mention the city of Addis Ababa, the capital of Ethiopia. They have actually sent health workers around to every door in the city already to interview people about their travel or exposure history and test them if necessary. If Ethiopia can do that, I refuse to believe Canada can't. We just need to understand better—and I'm not the person to give you the answer—what the administrative holdup is in the testing, but it's clearly administrative not scientific.

Mr. Don Davies: Thank you, Dr. Attaran.

I have one quick question for you.

Your chart spoke for itself. The question I have is why is Canada performing below comparative countries like Australia and other countries you mentioned. Your chart clearly shows we are. What are the reasons for that?

Prof. Amir Attaran: In terms of bending the curve, or the testing, specifically?

Mr. Don Davies: Bending the curve.

Prof. Amir Attaran: In terms of bending the curve, Dr. Fisman can be more detailed on this, but it's clear that we have not adopted as rigorous a lockdown as some other countries have. We've also had a slow-burning problem in the care homes and this has taken what could have been a sharp peak and broadened it into something of a plateau.

I am very uncomfortable with the fact that we are opening up without the testing at the necessary level, or the tracing. I'm not saying I don't want to open up. I hate being locked up as much as anyone else—you should see my children. There has to be groundwork done, and it is the fact that the governments of this country—some of them, especially the federal government—just haven't done the groundwork.

Mr. Don Davies: Thank you.

The Chair: That ends round one.

We will start round two.

Mr. Jeneroux, please go ahead. You have five minutes.

Mr. Matt Jeneroux: Thank you, Mr. Chair.

Thank you to the witnesses for joining us here again today.

I want to address Dr. Khan and some of the comments you made. In particular, I am hoping to get a grasp on when BlueDot—obviously ahead of the curve, early on—provided the first data regarding the coronavirus to the Public Health Agency of Canada.

Dr. Kamran Khan: As I mentioned in my opening remarks, our surveillance system had picked this up on December 31. You may also be aware that the Public Health Agency of Canada has a platform called the Global Public Health Intelligence Network, GPHIN. There are some parallels with the platform we're using. I think we may be using a bit more machine learning and artificial intelligence in our system.

I believe, with respect to awareness of the event in Wuhan, this was at a similar time; I believe it was around the end of December or beginning of January. We have had, as I mentioned, a relationship with the Public Health Agency, going past detection of threats and then looking at dispersion, how they might spread and where they might go next. All of the systems that we use internally—software systems, all of the internal data on commercial flights, passenger movements around the planet—are accessible by the Public Health Agency. This is part of our partnership.

I also did share the results of some of our analysis directly with Dr. Tam back in early January—I believe it may have been January 4 or 5, a few days after the new year. I communicated some of our initial findings and then had a follow-up meeting, I think, around the January 9 or 10 to discuss some of this in person.

● (1745)

Mr. Matt Jeneroux: What information did you provide exactly? Did you provide that information from December 31 that you had attributed to the beginning of this?

Dr. Kamran Khan: Because the Public Health Agency already has a surveillance system and GPHIN had picked up news of the outbreak in Wuhan around the same time as BlueDot, we didn't send them that information because it was something they already had access to. But we have been working with the Public Health Agency around contextualizing this.

Understanding that something is appearing in the world is very different from understanding what risk it presents to Canada and where those risks are greatest at the particular moment. Is it in British Columbia, in Halifax, or somewhere else?

We shared some of our findings on the movements of travellers across the world with Dr. Tam and her office and then met in person to discuss some of the results and, more broadly, really, the need for systems. We had some earlier comments about data internally within Canada. We're clearly not a closed population; we are a microcosm of the world, one of the most connected populations on earth.

It was critical for us to have better systems not only to detect threats but also to quickly assess what risks they present, so that we could be a step ahead and mobilize our resources, heighten our surveillance in the right places at the right time, and to share with you the specifics of the risks associated with the events in Wuhan. That was really just a few days after New Year's in early January.

Mr. Matt Jeneroux: Did you make any recommendations at that time about shutting down borders and what that would mean to Dr. Tam, and perhaps her team?

Dr. Kamran Khan: We discussed obviously what the risks were, but, of course, as you remember, in early January we didn't even know this was the coronavirus. Clearly it caused enough concern from our end just because there were some parallels with the SARS event that had emerged in late 2002 in Guangdong. We had some concerns given the parallels with SARS.

However, as more information became available, as soon as we knew this was a novel coronavirus, we did follow up directly with Dr. Tam and her office. Obviously, they were aware, but our concerns at that point were that we knew the last two novel coronaviruses, MERS and SARS, had killed a third and 10% of their patients, respectively. They have no known vaccines, no known effective antivirals.

A novel coronavirus means that the whole world is susceptible, and that's a lot of fuel for an outbreak, and it's in the middle of wintertime, which is when you have respiratory illnesses. Given the signal-to-noise ratio and the detection of this behind a whole background of febrile illnesses, that certainly caused us quite a bit of concern.

The last point I will make is that I believe it was on January 13 when the first case was reported in Bangkok. By the way, coincidentally, it was the top city that we had identified as being at risk. At that moment we knew this was not a few dozen cases. In order for there for cases to be showing up in a city of 11 million, we had to be dealing with hundreds, maybe even thousands of cases. That was really the moment we became quite concerned, but of course with emerging diseases, unfortunately, you learn as you go. You don't have all the answers and you have to make decisions as new information becomes available.

The Chair: Thank you, Mr. Jeneroux.

Mr. Matt Jeneroux: Mr. Chair, do you mind if I request that Dr. Khan share that early information he provided to the Public Health Agency with the committee?

The Chair: Sure.

Mr. Matt Jeneroux: Thanks.

Dr. Kamran Khan: I'd be happy to do that.

The Chair: Thank you, Mr. Jeneroux.

We go now to Dr. Jaczek.

Dr. Jaczek, please go ahead for five minutes.

Ms. Helena Jaczek (Markham—Stouffville, Lib.): Thank you very much, Chair.

Thank you to all the witnesses. This session has certainly been fascinating. There has been a real divergence of views, especially from the first three witnesses.

Thank you, all three, for your very considered opinions. We go from one extreme, with Dr. Attaran saying that we haven't gone nearly far enough, to Dr. Schabas saying that perhaps we have gone too far.

Speaking as a member of this committee, of course we're very interested in all of your opinions, but part of what we need to do is to find some commonality, to find where there is agreement. The area where there seems to be agreement, and that we have heard a great deal about from many witnesses, is that there needs to be more of a national data surveillance system as it relates to public health. It's been exemplified by many of you that in fact provinces are collecting data differently. Even in the use of the case definition, there has been a difference from province to province.

Dr. Schabas, given all of your experience, and having known you for so very many years in the trenches, in both urban and rural settings, I will address this question to you. At the end of your remarks, you made a comment in relation to a national surveillance system. I'd like to hear from you on what kind of data you would like to see and where the important areas are that need to be collected. I'm sure you've had to make decisions based on inadequate data, or not as much data as you would like to have had, on many occasions. Could you flesh out for us how you see that national surveillance system?

● (1750)

Dr. Richard Schabas: Thank you, Helena, and thank you again for arranging my invitation to this meeting. It's been great. It's been fascinating listening to David and Amir. Maybe at some point I'll have a chance to rebut some of the other things that have been said.

On the notion of having a national agency, we were always very envious of the Americans. They had the Centers for Disease Control, a highly respected agency that led and that took the high ground. It was where everyone turned to for advice and direction and guidelines. We had the old Laboratory Centre for Disease Control at Health Canada. There were some very good people there, but it didn't have the same clout—

The Chair: Dr. Schabas, could you speak a little bit closer to the mike and maybe a little bit slower for the interpreters?

Dr. Richard Schabas: I'm sorry.

The idea emerged almost 20 years ago—I actually wrote an editorial in the Canadian Medical Association Journal on this—of really proposing a national agency that would fulfill some of those roles. I think we had an opportunity 15 years ago after SARS, when there was this surge in interest in public health and improving our national public health capacity, which led to the—

The Chair: Pardon me, Dr. Schabas.

The interpretation has stopped. We'll suspend for a minute until that resumes.

● (1750)

_____(Pause)_____

● (1755)

The Chair: The meeting has now resumed.

Dr. Schabas, please carry on.

Dr. Richard Schabas: As I was saying, 15 years ago, the vision I had hoped we would adopt was not so much one of a federal agency, but a national agency. We had some resources with the federal government, but it was also a time when Ontario was developing Public Health Ontario and British Columbia was augmenting the BCCDC.

There was a real advantage in developing a sense of co-operation between the federal government and the provinces, because the reality is that the provinces collect the data and the provinces make most of the public health decisions. You don't have the federal authority to tell them what to do. They're going to do what they want to do. The only way to get consistency in a truly national approach to a problem like this is to get people to buy in, to get people to be willing to do it because they think it's the right thing to do and because the prestige of the direction they're getting from the national agency is sufficient for them to.... I'm not going to say fall in line, but be consistent with their approach.

We don't ever expect everything to be the same. Here's a great example: Why should British Columbia be doing with COVID what Quebec is doing? They are very different sorts of situations. I think we would all be much happier if we knew there was a common purpose, common objectives and a common directive.

I'm hoping, maybe a little naively, that there will be another surge in interest in public health—I'm sure there will be—after the COVID crisis comes and goes. I hope we rethink how we set things up. That's not a criticism of the Public Health Agency of Canada. I just think it would function better if it was better integrated with the provincial agencies and if the provinces and the federal government were truly partners in this.

The Chair: Dr. Jaczek, your time is pretty much up but because of the problem in the middle, I'll give you one more question.

Ms. Helena Jaczek: Thank you, Chair.

Dr. Khan, perhaps I can ask you. Obviously you and BlueDot have been very helpful to the Public Health Agency of Canada. What kinds of interactions have you and BlueDot had with the provincial agencies, such as Public Health Ontario?

● (1800)

Dr. Kamran Khan: We have had interactions with the ministry of health in Ontario and have been actively working with the province there. At BlueDot, we're a team of about 50 people. We're also working via Global Affairs Canada—

The Chair: I'm sorry, Dr. Khan. Please adjust your microphone.

Dr. Kamran Khan: I'm so sorry about that.

We are also working with Global Affairs Canada to support capacity building—as I mentioned in my opening remarks—in 10 countries in Southeast Asia. We're working with the State of California.

In many regards I think we would be very eager to support public health responses across the country and work closely with the provinces and territories. We've had, in some ways, an issue with respect to capacity to do this in the midst of the COVID-19 pandemic. However, we have had engagement at the federal level, and are producing analytics across the entire country on a week-over-week basis, and also with the Province of Ontario.

I'm not sure if that answers your question, but a lot of the analytics are focused on understanding issues related to social distancing and how that is related to epidemic activity. Also, keep in mind that while today we're in a bit of a lockdown, as the economy reopens and we have a highly susceptible population, we're going to have to start.... We may find ourselves in the same place as New Zealand in the future, where we have to start looking outward again and start to think about introductions that could trigger the next wave.

We've been involved in supporting both an internal look and tackling this in our own backyards, as well as monitoring the global situation and potential introductions.

The Chair: Thank you, Dr. Jaczek.

Dr. Kitchen, it's over to you for five minutes, please.

Mr. Robert Kitchen: Thank you, Mr. Chair,

Thank you, everybody, for your presentations today. They've been greatly appreciated.

Dr. Attaran, yesterday I spoke to Dr. Tam and asked her a question about data sharing between the provinces and organizations with the federal government. You've answered a lot of those questions I had for you, but further to that, I was asking her about demographic data, in particular how New York City has come up with a lot more demographic information, etc. She indicated to me that it's on the Public Health Agency of Canada's website, so I took the opportunity this morning to go onto that site. With some help from my staff, I finally managed to find some information on that.

They talk about updating the data as of today and about 4,201 cases of clinical presentations, and of those, 561 cases or 13% were clinically or radiologically diagnosed with pneumonia. My point about that is it provides a lot of information and then, all of a sudden, I find a little bit further down a little statement: “The epidemiology update is based upon information received for 38,746 cases. Not all data fields are complete, only cases with data available are included.” The bottom line is they're providing inappropriate information on the data that we have.

How is it that we ask you or other epidemiologists to come up with data and provide modelling when we put this out with inappropriate information?

Prof. Amir Attaran: Dr. Kitchen, thank you for a very intelligent question. You're exactly right. You mentioned there were roughly 38,000 cases in the data that you looked at. I'm going by memory here, but I think we've had about 80,000 cases reported in Canada so far, so that's under 50%. What that means is that at the high-water mark, anyone like Dr. Fisman or Dr. Khan doing modelling, or me when I do it in my amateurish way, are working with less than half a deck.

Mr. Robert Kitchen: Right, and—

Prof. Amir Attaran: There are obvious problems with that.

Mr. Robert Kitchen: When the Public Health Agency is making these decisions based on World Health Organization data, which is maybe coming in from China or wherever, which is inappropriate, again how do you come up with that proper information?

Dr. Fisman, do you have any comments?

● (1805)

Dr. David Fisman: I'll tell you, my group at University of Toronto call ourselves “data raccoons”, because we've sort of managed to thrive for about 15 years on data that most people regard as garbage, so it's sort of a bit of the normal state of affairs for us with public health data analysis. The stuff we have is pretty good by our standards.

Working with folks here in Ontario, there's been a modelling table convened over the last few weeks. We've been given access to case files. There's a lot you can learn, but there are also a lot of fields that are missing. We could potentially do better, but I think it's also important to remember that those fields are being filled in by very harried front-line public health epidemiologists.

I suspect that what you're seeing from the Public Health Agency of Canada is that they're putting out the data where they have complete fields, and that it's their way of dealing with missing data. Missing data is just part of epidemiologic data analysis. It happens no matter how good the data are that you have. I'd sort of want to know more about how they've made those decisions, but sometimes it's good enough.

Mr. Robert Kitchen: That's a challenge, though, when you don't have proper data and you don't understand that.

I'm going to go on a little bit further.

Mr. Ciciretto, you talked about high-quality antibody testing. We've heard a lot from you today and all of the witnesses about testing. Last week Health Canada approved the first serological test for detecting antibodies in those who contracted or may have contracted COVID-19. The approved serological test comes from an Italian biotechnology company.

Do we have the capacity to produce these tests domestically? Do you know that?

Mr. Vito Ciciretto: The answer to the question is, we do have capacity. The particular test that was approved was from a company called DiaSorin. We don't have that testing platform, in particular, so that's critical. Could we acquire it? Yes, we could acquire it.

There are other companies that we're working with right now, large diagnostics organizations that are looking to get Health Canada approval as well for a serological test. Once that happens, I have 200 collection centres and 850 phlebotomists who can collect those samples and bring them into a laboratory and onto existing test platforms that we have today that could do that testing quickly, efficiently and accurately.

The Chair: Thank you, Dr. Kitchen.

We'll go now to Mr. Kelloway.

Go ahead. You have five minutes, please.

Mr. Mike Kelloway (Cape Breton—Canso, Lib.): Thanks, Mr. Chair.

Hello, colleagues.

I want to say a really special thank you to the witnesses today. I'll echo Dr. Jaczek's that it's interesting to see such a rich series of viewpoints, insights, opinions and also backgrounds in a variety of areas. I really appreciate it. It's very illuminating.

Dr. Khan, I find your work very fascinating in terms of the technology you use. I don't necessarily want to look to the past but to potentially a second or third wave.

Can you talk about how your technology may be able to be used to track and identify, in many ways, a second or third wave? Could you illuminate a little bit what the biggest risk factor is that could trigger the next wave?

Dr. Kamran Khan: Maybe the way I could sort of frame what we have been building with the metaphor of a smoke detector and fire extinguisher. For six and a half years, we've been building systems to be able to detect threats early, because we know, as I mentioned, that time is our most valuable resource.

To be able to quickly go from detection to what kind of risks we are facing—not just from the dispersion of the disease, but what kind of disruption might occur—is very important because diseases spread around the world all the time. They don't all cause outbreaks or pandemics. That is a complex requirement because every disease behaves differently. Zika virus is different from Ebola, which is different from COVID-19 or measles for that matter.

We've been spending a number of years building up that capacity to have a bird's-eye view of what's happening around the planet, to be able to relate it to geographies across the planet, and to do this in, really, a matter of seconds.

With respect to once an outbreak starts to spread and is now occurring locally, this is where we have been using—again, I want to underscore, anonymously—just the pings, the digital locations from hundreds of millions of mobile apps and mobile devices.

That kind of information can help us understand. Ultimately, this is a virus that spreads, as Dr. Fisman mentioned, through the movements and interactions of people. These are really rich datasets—over three billion data points a day—that can really allow us to understand how those movements are occurring so that we can then start to anticipate how the epidemic might evolve. It also allows us to generate insights about some of the non-pharmaceutical interventions like physical distancing or recommendations for quarantine. Are those being adhered to at a population level?

I do want to highlight that we're not tracking anyone who is infected or their contacts. We're looking at population movement.

With respect to going forward to the next wave, I think the simple reality is that no one really quite knows what this is going to look like or exactly how it's going to unfold. We are dealing with a completely novel disease. Certainly, we have concerns that as we get into the latter months in the fall.... We know that coronaviruses tend to be in cooler, drier climates where they may be more efficiently transmitted. As that occurs, currently we are relating a lot of this mobility data to understanding how the epidemic curve is evolving. Perhaps there are lessons that we can learn about which geographies and which locations seem to be opening up society in such a way that they can, you know, generate some sense of normalcy and some kind of economic activity without having an exponential increase in the epidemic. I think that's really the $6,400 question. How do we do this gracefully? How do we thread the needle?

These are things that I, candidly speaking, don't know anyone has the answers for just yet. I think it goes back to the point that surveillance, testing and monitoring are critically important, because as we start to reopen society, it is going to be incredibly important for us to be watching very closely what the response is in terms of epidemic activity and transmission.

I hope that I perhaps have given you a little bit of a sense of what we're thinking going forward.

● (1810)

Mr. Mike Kelloway: You have.

I think you mentioned measuring disruption in society. Maybe I'm miscategorizing that.

Can you unpack that a bit?

Dr. Kamran Khan: Yes, thank you. It's a really big and very important issue.

The four Ds that we work on are detection, dispersion, disruption and dissemination. Detection speaks for itself, early detection. Dispersion mean, how do these things leap across continents in hours? How do we anticipate the next move? Without getting into a lot of detailed epidemiology, what sometimes is called the infectious disease triangle is a disruption or an outbreak that really lies at the crossroads of the characteristics of the microbe or the germ itself, the characteristics of the population, and the environmental conditions.

The Zika virus is not going to spread here locally in Toronto, because there's no mosquito and it's too cold; it might spread in Miami in July, but maybe not in January. That is a very complex set of data and we're bringing in hundreds of data sources, from real-time satellite data to insect observations, demographics, etc. We can do this for over 100 different diseases so we can try to get a sense of whether the necessary ingredients are there for this to actually cause a disruption, an outbreak.

As you can imagine, this is not a data problem. It requires deep subject matter expertise integrated with deep data analytical expertise and data science. This is the area we're actively involved in. We're well on our path and well on our way, but this is a formidable challenge that really is going to take years.

The Chair: Thank you, Mr. Kelloway.

Mr. Mike Kelloway: Thank you very much.

The Chair: We go now to Mr. Thériault.

Mr. Thériault, please go ahead for two and a half minutes.

[*Translation*]

Mr. Luc Thériault: Thank you, Mr. Chair.

My question is for Professor Fisman. Perhaps Mr. Schabas can express his opinion as well.

We do not yet have a vaccine or antivirals. Serological tests are just beginning. Faced with the desire for reopening, we have suddenly and a little hastily seen the notion of herd immunity appear. But there is no real certainty about the exact data, about the connection between COVID-19 and herd immunity.

Can you tell us where we are at in terms of knowledge or studies on herd immunity with COVID-19? Can you describe the situation?

If reopening were at an ideal rate, would we achieve herd immunity? At what rate would we need to achieve it to make everything safe?

● (1815)

[*English*]

Dr. David Fisman: Thank you very much.

There are a lot of moving parts here. Herd immunity can be approximated as a function of the reproduction number of the disease. The higher the reproduction number, the more people need to be immune if the disease is not to take off. That's why we see measles outbreaks when vaccine levels fall off just a little bit, because the reproduction number for measles in a susceptible population is about 20. You can get about 20 new cases from an old case.

This is a much less infectious disease. The reproduction number is somewhere between two and three. That means you need somewhere between half and two-thirds of the population to be immune to have herd immunity, so that if you bring an infectious case into the population you won't don't have an epidemic.

Where are we right now? We don't know. I've been doing a running meta-analysis on seroprevalence studies as they've come out. I'm up to about 50 of them. You can compare antibody prevalence in populations to what those communities think they have going on in the number of cases they have. It's called a cumulative meta-analysis, just adding study to study to study. The long and short of it is that I think we probably detect about 7% of cases. We have an inflation factor of somewhere between tenfold and twentyfold.

If we look at Canada with 80,000 recognized cases, that would be somewhere between 800,000 and 1.6 million cases in reality. That puts us—I'm going to get hung up in trying to do the math on the fly—at 4%.

If we're there now, New York is well ahead of us. New York has good seroprevalence data. They're at about 15%, but they had to go through hell to get there. They did experience a wholesale collapse of hospital systems in much of the city, including the Bronx and Queens, to get to 15%. That means they might be able to get to 50%, 60%, or 70% herd immunity by going through that a few more times. I don't think they will allow that to happen. They've lost approximately 20,000 New Yorkers of all ages, I would add, to get to that point.

What we have to do right now—a lot of countries around the world, indeed a lot of provinces in Canada, show us that we can knock this disease down to low levels and then we can use good public health practice. I agree with Dr. Schabas that you can't do contact tracing if you're having 200 cases a day, as we are in Toronto. It's just too much. If you're having five cases a day, you sure can. If you're testing a lot, you sure can. You need to use the distancing to knock the reproduction number down. We're still at around one in Quebec and Ontario. I would add that the Canadian epidemic, at this point, is a Quebec and Ontario epidemic. The other provinces have got the job done at this point. If you can do that, then we can start to use other public health measures, like contact tracing, to keep a lid on this and get through the summer and allow the economy to reopen.

We haven't touched on masks at all. There's pretty good ecological evidence at this point that the countries that are doing much better than us are mostly mask-adopting countries. You can argue the science, and we can have a symposium in five years about who was right, or we can use the precautionary principle and move towards masks now, which I think Dr. Tam has started to do.

We can do a lot to keep that reproduction number low and reopen our economy to a degree, and muddle through.

Exciting stuff is happening with vaccines. There are RNA vaccines that weren't on the table 10 years ago. There's a really exciting live virus vaccine from the U.K., where AstraZeneca, the pharmaceutical company, is manufacturing the vaccine at scale while the trials go on. If the trials are a success, they're going to have millions of doses ready to put into people's arms.

We need to avoid mass death situations until we can get through to a point where we can effectively deal with this pandemic. We will, but it's a matter of tenacity, patience and competence, and that's very patchy across the country. Some places have shown it; other places haven't. I'm sad to tell you that I feel that my province, at a provincial level, is one of the places that hasn't shown that, although individual local public health units have really shone and distinguished themselves.

● (1820)

The Chair: Thank you, Mr. Thériault.

We go now to Mr. Davies for two and a half minutes, please.

Mr. Don Davies: Thank you.

Dr. Fisman, last week, you stated, “I continue to be concerned that there hasn't been enough attention given to epidemiology in kids. I know folks are starting to study that in Germany and Switzerland, but we haven't really studied it in North America.” Then you said, “For those of us who have been really concerned about the possibility that children may be important vectors of this disease..”.

Given that we haven't done much research in North America and your concern that children may be important vectors, how do we square that with sending our kids back to school?

Dr. David Fisman: Honestly, it's a dilemma.

I think I mentioned earlier that the signature of this disease is that it takes off with big gatherings, so there's a lot you can probably reopen economically, safely, if you stay away from large gatherings of people. The one big gathering that's really, really tough to cancel—and which has huge economic implications—is at schools. That's the hardest thing.

The reason to be concerned about aggregating kids is that we see evidence from other respiratory infectious diseases that kids don't die of them, but they are tremendously good at transmitting these diseases.

Mr. Don Davies: That being the case, why would we be sending kids, who are vectors of this disease, to gather in large gatherings and to come back to homes where they may be in contact with seniors?

I don't see what the dilemma is there. What is the dilemma?

Dr. David Fisman: I think the idea is that economically it holds a country back. Even if we have 40% of our workforce able to work from home, for the parents, it's often difficult to get their jobs done if they're minding children in parallel.

However, yes, it's an issue. Countries like Korea have kept their schools closed. Hong Kong continues to have its schools closed. I think they're just starting to reopen, because they have approximately zero cases at this point.

I think places with good public health leadership have done it very cautiously. Kids are the transmitters of infectious disease for many respiratory diseases, even if they themselves tend not to be sick from them.

Mr. Don Davies: Thank you.

Dr. Khan, I will go quickly to you.

I know you did a commendable job. An article in U of T News said that BlueDot was among the first to warn the world of a potentially dangerous new illness, COVID-19. You rang the alarm on December 31, 2019, before both the U.S. Centers for Disease Control and Prevention or the World Health Organization. You also predicted the next 11 cities that the novel coronavirus would hit.

You're quoted as saying, “We didn’t necessarily know it would be of this size.... But what we did know is that it had the ingredients.”

Approximately when were you aware that COVID-19, or the novel coronavirus, had the potential for serious, significant, widespread transmission?

Dr. Kamran Khan: I think the point—and this is sort of a gradient—was literally December 31. First seeing that information certainly caused some alarm. Around the middle of January—and I'd have to double-check the exact date—was when the first case showed up in Bangkok.

I'll give you a bit of a sense of the increasing concern.

When we learned that this was a novel coronavirus, I believe somewhere around January 8 or so, there was concern for all the reasons I mentioned earlier, MERS and SARS, and comparing those: no vaccine, no effective antivirals, no underlying immunity and we were in the middle of flu season.

What we had been learning up until that point is that the number of cases being reported in China were in the dozens. When the case showed up in Bangkok, which was the top place we had concerns about because of the movement of travellers from Wuhan out into the region, in a city of 11 million.... The math doesn't work if you have a case show up in another city and knowing the volume of travellers who were leaving. That was the moment for me and our team, when we were really quite concerned.

Again, we didn't have all the answers, but we were quite concerned that this was a novel coronavirus. The outbreak was much larger than it appeared to be. This inevitably told us this was not just a spillover event. This was not just the people who were at the market who became infected. If there were hundreds or thousands of cases, this had to be something that was more efficiently being spread from person to person.

It was roughly around the middle of January that we had serious concerns about how this might unfold.

● (1825)

The Chair: Thank you.

That brings round two to a close. We start round three with Mr. Webber.

Mr. Webber, go ahead, please, for five minutes.

Mr. Len Webber (Calgary Confederation, CPC): Thank you, Mr. Chair, and thank you to all our presenters, whose opening remarks were very interesting indeed.

My first question is for you, Dr. Attaran. Thank you for sharing with the committee your paper on the pandemic data sharing. In this paper, you mentioned the SARS issue back in 2003 and how the World Health Organization demanded epidemiological data from Canada about the scope of the epidemic back then, particularly in Toronto. The problem was that Canada had no way to fulfill the World Health Organization's demand because of the jurisdictional fight that you described today with regard to data sharing.

Because of that, Health Canada was in no position to answer the World Health Organization's questions, so they grew afraid of Canada. They thought that Canada was concealing this epidemiological data, which then resulted in the World Health Organization recommending against travel to Canada, making Canada one of only two countries—that and China—that they sanctioned back then.

Sadly, I see this occurring again. Dr. Attaran, do you see this occurring? What will the implications be of being sanctioned once again?

Prof. Amir Attaran: Mr. Webber, you summarized that exactly right. Back in SARS, there were two countries in the world that got slammed with a WHO travel advisory, and we were one. China, not exactly having been honest, shall we say, was the other. Now, we weren't trying to deceive, the way China was. We were just unable to be honest. We were unable to get the data from Ontario to Ottawa and then onward to Geneva, where the WHO is.

Nothing has changed. That is a risk that could repeat itself. Yesterday, I believe it was Dr. Kitchen who asked about the multilateral information sharing agreement, which is an accord between the provinces and the federal government to share data. It is so secretive and ineffectual that to this day we don't know which provinces have signed that agreement and which have not. Can you believe it?

As for the Public Health Agency, I've asked them that question directly. Which provinces have signed the information sharing agreement and which haven't? They won't answer the question. Parts of that agreement actually stand in the way of data analysis, the sort that Dr. Fisman does. Under that agreement, provinces have to give their permission before analyses using their data can be published, which means that they have the ability to suppress analyses that can save lives. It's terrible.

Mr. Len Webber: It's unbelievable, Dr. Attaran, it really is. Thank you for sharing your testimony today.

Dr. Fisman, again, thank you as well, and thank you for your work, your commitment and your sacrifices, too, along with those of all health care workers in Canada. Thanks to all of them.

You've talked about some of the best practices around the country. It's in Nova Scotia, I think, that you indicated they hunt the virus, and you also talked about how in Saskatchewan they deal swiftly with and contain areas of outbreak.

Then you talked about Alberta and how they've scaled up their testing and are the most potent and aggressive testing province in the country. I'm just at odds here. I don't understand. How come Alberta can do it but the rest of Canada cannot? Where are they getting their testing material? What's their secret in Alberta?

● (1830)

Dr. David Fisman: Do you know what? I'm not sure to what extent I can talk about private conversations in this public forum but, as I speak to colleagues across the country, what is clear to me is that the places that got the job done were aware of their deficiencies as laboratory systems and worked with commercial partners to automate processes in their labs. It's one thing to be testing 100 specimens a day. It's another to be testing 10,000 a day.

I think that the laboratories that are able to have high throughput here, and—Mr. Ciciretto is probably the better one to answer this question—we do have folks in the country who know this stuff. From the time the specimen arrives until the report goes out to the public health unit, not by fax but electronically, operations can be tremendously streamlined so you don't get the bottlenecks that we've had in Ontario.

I think a lot of the problems got blamed on the supply chain but clearly, as the supply chain has cleared up, it's still a rocky ride. In Ontario there have been a lot of politics as well. I think you see that. You've had access to some testing data via the modelling process. You see that there's still this hugging going on where, even as testing is supposed to get dispersed out to hospital labs and private labs, it's still getting hugged by the public health laboratory system.

I think, in a time of national crisis, it's time to check your ego and work with whoever you can work with. Essentially, the folks in Newfoundland.... It was a remarkable experience to interact with them. Perhaps this is a size thing, but it seemed a lot to me like an ego thing. They have a provincial working group that has some former politicians, some leaders from health, leaders from business and a couple of academics, and they're all at the table and they're all exchanging ideas. It reminds me of the children's story, *Stone Soup*, where everyone brings something and puts something in. At the end of that, they all have a good soup to enjoy together.

That's how they do it in Newfoundland. It was a revelation to me, as someone coming from Ontario who's used to being asked for information that then goes off into a dark place and you're never really sure who's seen it, used it or responded to it. It's just a very different way of doing business, and I think it's served them well. They got the idea of hunting the virus from Iceland. They looked over to the east and thought, “Well, you know we've got Canada over to the west and we've got this other country over to the east, and the country to the east is doing a bang-up job. Let's talk to them.”

I think being humble and looking for folks who are doing this better than you, and learning from them, is part of the magic.

Mr. Len Webber: Absolutely, it is.

The Chair: Thank you.

Mr. Van Bynen, go ahead, please. You have five minutes.

Mr. Tony Van Bynen: Thank you, Mr. Chair. Thank you, Dr. Fisman, for joining our committee today. It's so refreshing to hear such a wide variety of perspectives, and that certainly helps us to develop a good understanding of the situation that we're trying to find some solutions for.

It's my understanding that you co-authored a study that examined the impact of enhanced contact tracing and restrictive physical distancing measures in comparison to a combination of enhanced contact tracing and less restrictive distancing measures.

Could you please share with the committee the findings of your study and what the implications may be?

Dr. David Fisman: I think what you're referring to was our paper in the Canadian Medical Association Journal, CMAJ, in March. Our model looks a lot like most other models by competent modelling groups. It looks like the publication by a guy named Steve Kissler, in Science, that happened about a month after.

What we projected was that reducing transmission through a variety of means can knock down the reproduction number of the disease and prevent intensive care units from overflowing. Something we learned.... We didn't really anticipate that a lot of deaths in Ontario would come in the long-term care facilities. We knew that long-term care facilities were vulnerable, but we assumed, as we were doing our modelling, that people would try to protect them, which turned out not to be the case.

What we've found is that various combinations of case identification with contact tracing or straight physical distancing are sufficient to knock the reproduction number down enough that ICUs don't overflow. This has been the case in Canada, which is wonderful.

Moving forward, we now have a second iteration of that model in press, in a journal called Annals of Internal Medicine. Thanks to the provincial modelling table, we've been able to calibrate the model. That means we've fit the model to real data. We couldn't do that beforehand because we didn't have an epidemic to fit it to. We can fit it to ICU occupancy in Ontario and can fit it to hospital deaths. The long-term care stuff is very challenging to try to fit into any sort of model. What we see is that, basically, the lower disease activity goes and the slower we reopen, the longer it will be before we have a resurgence.

In our paper in March, in the Canadian Medical Association Journal, my colleague, Dr. Ashleigh Tuite, who I've referenced previously and is a brilliant modeller, came up with the idea of dynamic social distancing, which depends on really good public health surveillance, so that you know when your hospital is starting to fill up again and when you have to strengthen distancing measures. I really think the group at Harvard, who we're friends with, may have copied that from us. That came out in the Science paper as well a couple of weeks later. It's this idea—and journalists refer to it as surfing the wave—that we're likely to go up and down and up and down with this disease for a while until we have a vaccine, which may come sooner than I ever would have imagined.

● (1835)

Mr. Tony Van Bynen: Thank you.

Yesterday I asked Dr. Tam about the provinces and territories and their plans to reopen their economies, as well as people starting to leave their homes as the weather gets nicer. As a follow-up, with the information obtained from your study in mind, what are your thoughts on how this can be implemented safely?

Dr. David Fisman: This is not our work. There's a marvellous mathematician at Waterloo by the name of Chris Bauch who has a paper looking at regional reopening in Ontario as opposed to blanket policies, with the outcome of interest being how we can minimize the amount of time in lockdown.

I think some organic reopening is happening anyway as the weather gets better, and that's all right. This doesn't seem to be an infectious disease that spreads particularly well in parks or as people are out enjoying themselves, as long as they're maintaining a bit of distance. This disease really continues to show that it likes big crowds and indoor places. I think our most recent superspreader event here in Ontario was among greenhouse workers in Chatham, which fits the description to a T: 50 people were infected working in a greenhouse. When folks are in small groups and there's a low upper bound on the number of people they're working with—we call that “work bubbles”—or when folks are enjoying themselves outside to stay fit, going to parks or enjoying the outside with their kids, that generates minimal risk for us.

What we do need is good, strong surveillance systems—and this circles back to our initial conversation about testing—that let us know when we're getting into danger again, as we were in March. I do think we're going to struggle in the fall. Again, there's a lot of hindsight at this point. This thing emerged in January, but we didn't really get serious about it until March, and I think we're going through that again. Anyone who looks at disease dynamics for a living can tell you that we're in a lull now but the disease is probably going to be coming back in September or October. We have some golden time now to get prepared for a likely resurgence in the fall. I think we need to build those surveillance systems and get much better at this by the time we get to the fall, because we're going to have to be more nimble then. There's much we can do, and there's much we can do safely if we avoid large gatherings.

The bubble idea—and a lot of corporations have already instituted this— is simply that if you divide people up into relatively small teams, they don't work simultaneously in the office and there's a deep clean between when teams are in the office, you have an upper bound on how many people are going to get infected if someone comes into the bubble with infection.

I think there's a lot of ingenuity and a lot of wiggle room in reopening the economy safely, as long as we have the surveillance systems that allow us to see when we're getting back into trouble.

The Chair: Thank you.

Ms. Jansen, please go ahead. You have five minutes.

Mrs. Tamara Jansen: Dr. Khan, I'm curious about your thoughts, as a infectious disease specialist, on the current deal that Health Canada has made with China on developing a COVID-19 vaccine.

The announcement mentioned that the National Research Council is working with CanSino Biologics to advance a vaccine, which is being developed jointly with the People's Liberation Army. Apparently Health Canada has even approved the first human clinical trial that will be run at Dalhousie University in spite of the fact that CanSino has not published any data from its first trial phase for any sort of public scrutiny.

This really shocked me. Vaccine development cycles are normally 10 to 15 years, and the shortest ever was four years. Our Five Eyes intelligence alliance has raised concerns regarding China's transparency regarding this particular pandemic. They even denied, initially, human-to-human contact. And some whistle-blowers have disappeared.

If we want Canadians to buy into a COVID-19 vaccine, wouldn't it make more sense to be working with a more trustworthy partner on this sort of thing? Does it strike you as being dangerous?

● (1840)

Dr. Kamran Khan: Thank you for the question. I'm going to try to see if I can tackle it.

With respect to vaccine development and partnerships, I would say that I'm not fully aware of all the details of how Canada is looking at vaccine development, perhaps, with the Government of China or with scientific groups in China.

I think all of the points that you've raised are very important. Clearly, there is a race to get to a vaccine as quickly as possible, not only from a preventative standpoint but also to develop therapeutics.

I think I'm probably not well equipped to speak to the broader ethical issues here. I'm just less informed about the specifics of this particular circumstance.

But clearly, the points that you're raising around transparency are critical in any scientific endeavour. I think that is a critical issue.

I'm not sure if, perhaps, Vito or others want to chime in on that.

Mrs. Tamara Jansen: My time is limited. I have another question, but not specifically for you.

Going back to Professor Attaran, you mentioned that we could ask you questions about yesterday's meeting.

I asked Dr. Tam about her flip-flop on the use of masks. Up until early April, Dr. Tam stated that an asymptomatic person shouldn't wear a mask. It didn't work. It might even be harmful. Then on April 6, she changed her mind and said that a mask was good for additional protection.

Her response to my question on why her message changed was that, apparently, new evidence had come to light.

As this was a respiratory pathogen, I imagine that out of the abundance of caution, masks would have been helpful right from the beginning.

In your opinion, what sort of new evidence has come to light over the course of this pandemic that would substantively change the way we consider the effectiveness of masks as prophylactics?

Prof. Amir Attaran: There's no easy way for me to say this, but Dr. Tam was not being truthful.

In the week or 10 days.... Pardon me, I don't know the exact time span between her statement that masks were not to be recommended to the public and then changing her view to give permissive guidance that masks of a non-medical sort could be used. In that short period of, as I say, about a week or 10 days, there was no new evidence that emerged to justify that change.

There have been additional studies of masks, of course, some of it biophysics, what particle size will penetrate a mask in what conditions. But there was definitely not in that crucial window a game-changing study.

Mrs. Tamara Jansen: I have a really quick question. My time is almost out.

You provided a chart in your submission that showed that Australia and, I believe, South Korea had much better pandemic trajectories than Canada did. As with all catastrophic emergencies, there's never just one thing that goes wrong that causes the tragedy, and I assume that's the same when things go right.

What, in your estimation, are the critical things that ensured better outcomes in those countries compared to Canada?

Prof. Amir Attaran: Australia, for instance, was very quick at cutting off travel with China. It did so at the same time as President Trump did, but for sounder reasons than Mr. Trump.

It was also incredibly quick at organizing coordination between the states—the provinces, if you will—and the federal government. As I mentioned, they signed an accord on co-operation on March 13. Such an accord doesn't exist in this country yet.

The Australians have, generally speaking, a very strong sense of biosecurity because they are an island continent and they have honed that over years. They're much more attuned to risks coming in from abroad than we have been. The error of not being tougher on travel sooner is one that we will, of course, regret for many years to come.

The Australians also, I feel, were extraordinarily good at their social distancing. Now, precise measures of how aggressive social distancing is are hard to come by. Dr. Fisman would be able to speak to that far better than I could, but even from my inexpert point of view on this, it's clear the Australians did take the social distancing more seriously early on than did Canadians, and that has had an effect.

● (1845)

The Chair: Thank you.

Ms. Sidhu, go ahead, five minutes.

Ms. Sonia Sidhu (Brampton South, Lib.): Thank you, Chair.

Thank you everyone for coming today.

As you know, I really like all the witnesses. Yesterday Dr. Tam and her team were here.

This committee has really been focusing on supporting Canadians and how we can better help all Canadians.

Today I really want to say thank you to all the witnesses and my first question is to Dr. Khan.

You talked about the rigorous factor and triggering the next wave. Can you explain to the committee how your technology can be used to track second or third waves of COVID-19? What do you see as the biggest risk that's coming?

Dr. Kamran Khan: In the technology that we've developed, and I'm going back to that metaphor of smoke detector and fire extinguisher, we've really been focusing much more on developing the early warning systems that could give us a signal that there is a threat coming.

COVID-19 is here now and we're all very well aware of it and we're now sort of more in firefighting mode, grabbing the fire extinguisher to put fires out.

From the standpoint of our technology, the area where we are supporting public health decisions is around an understanding of population movements and how that relates to the transmission of COVID-19 across the country.

With respect to the next set of waves, I have two thoughts. One is clearly the vast majority of the population in Canada remains susceptible, as we've heard. We either could see an uptick in cases later in the fall because of a variety of factors including climate conditions and dynamics of how people are interacting, or we could find ourselves in a similar position to some countries like Australia and New Zealand, where imported cases become the catalyst for another wave.

So we're going to have to be thinking both internally and externally. These are a couple of examples of how our technology is looking internally within the country domestically as well as globally.

Ms. Sonia Sidhu: Thank you.

My next question is for Mr. Ciciretto. Your company is based in Brampton. Your company recently moved to providing COVID-19 test results online instead of over the phone. How has that increased the efficiency of your testing process?

In Canada today, 1.3 million people have been tested. What do you think? How has online reporting instead of over the phone reporting increased the efficiency of your testing process?

Mr. Vito Ciciretto: The ability to transmit results directly from an analyzer onto your laboratory information system and into provincial health repositories is critical from at least two perspectives. One is from a timeliness perspective. As soon as that test result is available you want to make sure that you're able to release it.

The second and perhaps even more important perspective has to do with accuracy. The minute that there's any type of human interaction, of taking a manual result from a machine and then transmitting it onto a computer, there's always that risk of error, and that's not something you want, obviously.

● (1850)

Ms. Sonia Sidhu: Dr. Fisman, as you know the Public Health Agency has its opinion on non-medical masks.

You also mentioned the mask adoption strategy; how is this beneficial to Canadians?

Dr. David Fisman: We don't know but we can be highly suspicious that it would help us a lot. Especially if we can get the reproduction number of the disease down to around one. That's a tipping point. At that tipping point, very small changes in infection transmissibility can really make the epidemic fall through the floor and go away.

What you have to remember about masks and disease like this is that masks work in both directions. They reduce the likelihood that you get infectious particles into your nose, mouth and eyes potentially, if you keep your hands off your face. They also prevent you from infecting other people. Probably the more important part with this disease is the reduction of transmission, which happens very efficiently even with cloth masks. The reason that's so important with this particular disease is that what we know of the work of Gabriel Leung and his colleagues in Hong Kong, which was published in Nature about a month ago, is they estimate about 44% of transmissions in Hong Kong occur in presymptomatic individuals. Those are people who are going to feel sick tomorrow, but they feel just fine today. They haven't changed their behaviour.

Masks can be extremely impactful because if I'm wearing a mask and I become infectious but I don't know it yet, I don't infect you. Everybody wants to wear a mask to protect themselves from other people. I'm fine to have folks leverage that to get the masks on. It's pretty clear. There's a reason why surgeons wear masks in the operating room because they block extrusion of respiratory droplets that infect with bacteria the patients they're operating on. This would be the same idea except out in public you're wearing a mask not to protect yourself necessarily—although it might—but to protect other people from you if you're infectious but don't have symptoms.

As I say, we've had reproduction numbers in Ontario and Quebec, which is basically where our epidemic lives now, rumbling along around a reproduction number of one. In Ontario it's been there since early April, we just can't seem to get it down. If anything knocks that reproduction number down to 0.7 or 0.6, we're going to get back to a lot more rapid economic opening up. We're going to be able to open up more. The lower we keep that reproduction number, the more we'll be able to open up the economy while still staying safe.

To me it's a no-brainer. We can argue about class 1A evidence or what have you. We can have a symposium about this in five years and decide what exactly the science shows. But now is the time for action.

As Professor Attaran said, we're burning through $12 billion a week. Getting masks on Canadians and teaching them how to use them is change from between the couch cushions relative to what we're burning through by keeping our society closed. To me it's worth the gamble.

● (1855)

The Chair: Thank you.

We go now to Mr. Desilets for two minutes and a half, please.

[*Translation*]

Mr. Luc Desilets (Rivière-des-Mille-Îles, BQ): Thank you, Mr. Chair.

My thanks to all the witnesses for joining us. The content they have shared with us is very interesting.

My first question is for—

[*English*]

The Chair: Pardon me, Mr. Desilets, your sound is bad as well.

Could you try and unplug your headset and plug it back in?

I will suspend for a minute.

● (1855)

_____(Pause)_____

● (1900)

The Chair: I declare this meeting resumed.

Please go ahead, Mr. Thériault, on behalf of Mr. Desilets.

[*Translation*]

Mr. Luc Thériault: Okay.

Earlier, when I asked Dr. Fisman a question, I noticed that Dr. Schabas was reacting. I think he wants to answer the question.

It had to do with the rate of safe reopening that Canada should adopt in order to have herd immunity, given that we don't have a vaccine yet, we don't have antivirals, and we are just beginning serological testing.

My question is for Dr. Schabas.

[*English*]

Dr. Richard Schabas: One really profoundly unfortunate thing about what's happened in Canada, where we in fact did the lockdown in advance of our outbreak, unlike many places in western Europe or in the United States, is that in a sense we've had the worst of both worlds. We have achieved very little herd immunity, certainly no more than 5%, at least in the whole country, yet we've had a lot of deaths. We've had a lot of deaths because of the outbreaks in the long-term care homes. The population death rate in the city of Montreal is twice as high as it is in Stockholm, Sweden and is starting to close in on the city of New York. It's not been a very happy experience.

There were two kinds of outbreaks. There was the long-term care outbreak, which drives mortality, and then there's the community outbreak, where there has been very little mortality.

The fundamental question is: Is it safe to reopen in the presence of active disease? No, not in the sense that we're not going to see more COVID disease. We will. When we start to open up, we are going to see more COVID disease.

The whole thrust of my presentation is to look at it the other way. Is it safe not to open up? We talked, and one of the earlier questions was: When are we going to open the schools? Why are we opening the schools? There's going to be more COVID spread. Well, the reason you open schools is that children have to go to school. It's a fundamental right of children to have an education. If we deprive a whole generation of children of six months or a year of education, we're going to be paying the public health price for that for years to come.

There is no nice solution. Dr. Fisman and Dr. Attaran talk about doing more testing and contact tracing, something which, by the way, has never been done to control a respiratory virus. It may work well on a spreadsheet; the real world is more complicated. I hope they're right. I hope they're right and that works, but the real world is a rather more complicated place.

I was just going to say what I'm really worried about is that when they try the strategy and the disease resurges in the fall and the strategy fails, as I believe it almost certainly will, we can't go back into this kind of lockdown because we will do more long-term damage to our public health than COVID-19 could ever do.

● (1905)

The Chair: Thank you, Mr. Thériault.

We go now to Mr. Davies.

Mr. Don Davies: Thank you.

Dr. Schabas, you wanted a chance to explain, so I'm going to put a few things to you. After SARS, you wrote, “In the unlikely event of another SARS outbreak in Canada, public health officials should quarantine no one.” Now, our current pandemic is a SARS outbreak. The virus is SARS-CoV-2. We fought it mainly with lockdown and quarantine. My first question is, are you standing by your extraordinary statement that we should quarantine no one?

Before I get to that, I want to contrast that. In 1990, when you were Ontario's chief medical officer, you classified HIV as a virulent disease, which is the worst category of characterization, and you recommended that we forcibly confine people with HIV who may have had sex with someone else, even if they used a condom and even if they disclosed that to their partner.

My final piece, before I let you answer, is that you said that we should treat this more like the 1957 flu, but the fatality rate in the 1957 flu was about 0.1%, which is about one-twelfth that of COVID-19.

Throwing all those together, can you help me understand your point of view?

Dr. Richard Schabas: I'll try to remember all of them.

First of all, let me start with the SARS 1 and the quarantine. I was talking about SARS 1. SARS 1 was a disease that was not transmissible asymptomatically and was not even transmissible in its early symptomatic stage, so quarantine made zero sense with SARS 1, and my hope was that it wouldn't happen again.

Yes, we've used it widely in SARS 2. Whether it's really been very effective, or whether it's a useful tactic, because as I've said before, you can maybe flatten the curve.... In fact, I'm quite impressed by our ability to implement quarantine, and I think it probably has to some degree flattened the curve, but the question is ultimately to what end? The virus isn't going anywhere, and unless the measures you're using to flatten the curve are somehow sustainable in the long term, I'm not sure they really get us anywhere.

On the third question, as related to HIV, yes, I had recommended it. I didn't do it. It wasn't up to me. I had recommended to the minister that it be classified in the same category as diseases like tuberculosis, syphilis, gonorrhea and hepatitis B. It was a classification that would give a judge the authority to incarcerate someone who was deliberately spreading the disease. That was the context of it. It actually never happened, and that's not quarantine. Please understand that quarantine is when you lock someone up who you think is incubating the disease.

Case isolation, which is a totally different thing, is that when you know somebody has the disease, you take steps to isolate them. I'm not recommending that we do this for HIV. That's a different context. That's what we do, in fact, when people have COVID or we have good reason to believe they have COVID. We isolate them. That's not quarantine. Quarantine is when you lock them up when you think you're incubating them.... The term “quarantine” itself derives from the 40 days of Lent. That's a medieval strategy and, by and large, I think it belongs back in the Middle Ages.

● (1910)

The Chair: Thank you.

Mr. Don Davies: I have a point of privilege to raise before we adjourn, Mr. Chair.

I would like to move a motion that this committee inquire into reports that a witness appearing before the health committee, Dr. Amir Attaran, may have been threatened, punished, intimidated or otherwise harmed by the Public Health Agency of Canada, Statistics Canada or the federal government in some other form, because of testimony he has given at the health committee, and to determine if a prima facie issue of privilege has been raised and, if so, report such findings to the Speaker of the House.

Mr. Chair, I'm quoting from Bosc and Gagnon, which says this:

> ...the intimidation of a committee witness has also been found to be a prima facie breach of privilege. In 1992, a witness who had testified before a subcommittee was advised by a Crown corporation employee that the issue of her testimony was being referred to the corporation's legal department. The witness informed a Member, who raised a question of privilege in the House. The matter was found by Speaker Fraser to be prima facie contempt and was referred by the House to the Standing Committee on House Management for consideration.

In its report, the committee said this:

> The protection of witnesses is a fundamental aspect of the privilege that extends to parliamentary proceedings and those persons who participate in them. It is well-established in the Parliament of Canada, as in the British Parliament, that witnesses before committees share the same privileges of freedom of speech as do Members. Witnesses before parliamentary committees are therefore automatically extended the same immunities from civil or criminal proceedings as Members for anything that they say before a committee. The protection of witnesses extends to threats made against them or intimidation with respect to their presentations before any parliamentary committee.

Mr. Chair, I could go on. There are many more. I move that there has been a violation of my privileges as a member of this committee, and I would ask that you act on the motion that I have moved.

The Chair: Mr. Davies, you're in a point of order. You can't make a motion on a point of order.

As far as the question of privilege goes, as I mentioned earlier, I believe that's out of scope for our authority to conduct these video conference meetings. We are restricted to solely receiving evidence relating to the government's response to COVID-19, and we are also allowed to make motions regarding the invitation of witnesses.

Certainly, as I've mentioned before, I will take the matter under advisement. I will look for a legal opinion from the clerk and from the legal clerk as well, and we can take this up at another time. I'll take that under advisement and—

Ms. Sonia Sidhu: Mr. Chair, I would like to raise a point of order.

There were comments made in testimony today that I believe break parliamentary language. It was deeply disrespectful to call Canada's public servant untruthful. That comment should be removed from the committee record.

The Chair: Thank you for that point of order.

Certainly, we are bound by the rules of Parliament in our conduct here. I would certainly urge all participants, going forward, to be prudent in their language.

Thank you, everybody. I'd like to—

Mr. Matt Jeneroux: Mr. Chair, this is to Mr. Davies' point of order.

The Chair: Go ahead.

Mr. Matt Jeneroux: I'm reading the motion adopted by the House of Commons in the sitting on Tuesday, March 24, 2020. Section (i) states the following:

> ...if committee is not satisfied with how the government is exercising its powers under the Act, it may adopt a motion during a meeting by videoconference or teleconference to report this to the House by depositing a report with the Clerk of the House which shall be deemed to have been duly presented to the House on that day;

I would point to you, Mr. Chair, and also the clerk, to reference that point when coming back and addressing Mr. Davies' question of privilege.

Mr. Don Davies: If I might, Mr. Chair—

The Chair: I'm sorry, I—

Mr. Don Davies: —I want to be very clear that I am not raising a point of order. I am raising an issue of privilege.

I can further quote that it says in the—

The Chair: Just hold on, Mr. Davies.

Thank you, Mr. Jeneroux, for your contribution.

I believe you did start your remarks, Mr. Davies, on a point of order. You then went into a question of privilege. It's kind of beside the point. I will take under advisement your motion. We will get back to you once I have a ruling from the law clerk.

● (1915)

Mr. Don Davies: Mr. Chair, with respect, it's very important that you....

You're misunderstanding my point. Earlier I raised a point of order. I am now raising a question of privilege. That's what I did in my second intervention. You clearly have the power, in fact you have the duty, to receive my question of privilege as it's raised in committee, because this is where I have to raise that.

I'm happy for you to go back and reflect on it, but I want to be very clear that I am raising a question of privilege and I am asking for your consideration of the motion that I have moved.

The Chair: Thank you, Mr. Davies. As I said, I will take the matter under advisement. We will get back to the committee in due course.

Mr. Don Davies: Thank you.

The Chair: Thank you, everybody.

Thank you to our witnesses. It's been a lively and robust discussion. Thank you for sharing so much of your time with us and for putting up with our technical issues.

Thank you to the House staff and the technical people for being with us to work through those issues and thank you to the members for all the great questions.

Have a good day, all, and thank you.

The meeting is adjourned.

Published under the authority of the Speaker of the House of Commons

SPEAKER'S PERMISSION

The proceedings of the House of Commons and its committees are hereby made available to provide greater public access. The parliamentary privilege of the House of Commons to control the publication and broadcast of the proceedings of the House of Commons and its committees is nonetheless reserved. All copyrights therein are also reserved.

Reproduction of the proceedings of the House of Commons and its committees, in whole or in part and in any medium, is hereby permitted provided that the reproduction is accurate and is not presented as official. This permission does not extend to reproduction, distribution or use for commercial purpose of financial gain. Reproduction or use outside this permission or without authorization may be treated as copyright infringement in accordance with the Copyright Act. Authorization may be obtained on written application to the Office of the Speaker of the House of Commons.

Reproduction in accordance with this permission does not constitute publication under the authority of the House of Commons. The absolute privilege that applies to the proceedings of the House of Commons does not extend to these permitted reproductions. Where a reproduction includes briefs to a committee of the House of Commons, authorization for reproduction may be required from the authors in accordance with the Copyright Act.

Nothing in this permission abrogates or derogates from the privileges, powers, immunities and rights of the House of Commons and its committees. For greater certainty, this permission does not affect the prohibition against impeaching or questioning the proceedings of the House of Commons in courts or otherwise. The House of Commons retains the right and privilege to find users in contempt of Parliament if a reproduction or use is not in accordance with this permission.

    - Appendix A - Factors Affecting Pandemic Impact
    - Appendix B - Pandemic Risk Assessments

Preface

Canadian Pandemic Influenza Preparedness: Planning Guidance for the Health Sector (CPIP) is a federal, provincial, and territorial (FPT) guidance document that outlines how jurisdictions will work together to ensure a coordinated and consistent health-sector approach to pandemic preparedness and response. CPIP consists of a main body, which outlines overarching principles, concepts, and shared objectives, as well as a series of technical annexes that provide operational advice and technical guidance, along with tools and checklists on specific elements of pandemic planning. The CPIP main body and its annexes are intended to be used together.

CPIP was first published in 2004. In 2006, the Pan-Canadian Public Health Network (PHN) Council approved an updated version of CPIP as an evergreen document to be updated as required. In 2009, Canada’s pandemic preparedness planning efforts were tested for the first time, with the emergence of the H1N1 influenza pandemic. In 2012, a CPIP renewal process was initiated by the PHN Council. This latest version of CPIP, was approved by FPT Deputy Ministers of Health 2014, with further update in 2018. It incorporates evidence from H1N1 lessons learned reviews conducted at the FPT and international levels and by various stakeholder groups, and scientific advances. As an evergreen document, the CPIP main body and each annex will be reviewed every 5 years, with updates made between review cycles, if necessary.

Since 2012, The CPIP Task Group (CPIP TG) has overseen the CPIP renewal process.The CPIP TG consists of members with expertise in the areas of pandemic and seasonal influenza, pandemic preparedness planning and response, emergency management, epidemiology, public health, virology, bioethics, immunization, surveillance, and laboratory diagnosis.

The updated CPIP allows for a more flexible and adaptable response to future pandemics, providing scope for provinces and territories (PT) to adapt their own plans and responses to local and regional circumstances. The title of the document also has changed, from Canadian Pandemic Influenza Plan for the Health Sector to Canadian Pandemic Influenza Preparedness: Planning Guidance for the Health Sector, to more accurately reflect its role and intended use as a guidance document.

CPIP now supports a risk-management approach and includes new concepts such as pandemic impact assessment, descriptions of pandemic scenarios of varying impact, and identification of triggers for a Canadian response. It also better reflects Canada's geographic, demographic, cultural, and socio-economic diversity and the imperative for planners to take this diversity into account. CPIP has been subject to extensive FPT government review and targeted stakeholder consultations. Stakeholders included national-level organizations representing health professionals, emergency preparedness and first responders, community services, the private sector, and Indigenous peoples.

1.0 Introduction

1.1 Background

Canadian Pandemic Influenza Preparedness: Planning Guidance for the Health Sector (CPIP) provides planning guidance to prepare for and respond to an influenza pandemic. Influenza pandemics (subsequently referred to as pandemics) are unpredictable but recurring events that occur when a novel influenza virus strain emerges, spreads widely and causes a worldwide epidemic. Unfortunately, it is not possible to predict the anticipated impact of the next pandemic or when it will occur.

Planning for a prolonged and widespread health emergency of unpredictable impact is challenging but essential. It requires a "whole of society" response and the coordinated efforts of all levels of government in collaboration with their stakeholders.

Pandemic planning activities within the health sector in Canada began in 1983. The first Canadian pandemic plan was completed in 1988 and was followed by several updates. In 2004, the Canadian Pandemic Influenza Plan for the Health Sector was published as the result of extensive collaboration among FPT and other stakeholders. Before this version, the last major update to the CPIP and its annexes occurred in 2006.

The 2009 influenza A (H1N1) pandemic (subsequently referred to as the 2009 pandemic) provided the first real test of Canada's pandemic preparedness planning efforts. Collaboration among all levels of government and stakeholders was unprecedented compared with previous events like the Severe Acute Respiratory Syndrome (SARS) outbreak in 2003. The public health and health care systems were stressed but in most instances were able to cope. Antiviral stockpiles were deployed and pandemic vaccine was administered to millions of Canadians. There were, however, many challenges identified in this experience.

Canada's pandemic planning continues to evolve on the basis of research, emerging evidence and the lessons learned from the 2009 pandemic. The value of building on seasonal influenza surveillance systems and control measures is well recognized. Making these systems and measures as robust as possible in the interpandemic period will help prepare for a strong pandemic response.

1.2 Purpose

CPIP's overall purpose is to provide planning guidance for the health sector for pan-Canadian preparedness and response, in order to achieve Canada's pandemic goals:

> First, to minimize serious illness and overall deaths, and second to minimize societal disruption among Canadians as a result of an influenza pandemic.

The main body of CPIP provides strategic guidance and a framework for pandemic preparedness and response, whereas the CPIP annexes provide operational advice and technical guidance, along with tools and checklists. As an evergreen document, CPIP will be updated as required to reflect new evidence and best practices.

It is important to note that CPIP is not an actual response plan. Rather, it is a guidance document for pandemic influenza that can be used to support an FPT all-hazards health emergency response approach. While CPIP is specific to pandemic influenza, much of its guidance is also applicable to other public health emergencies.

1.3 Audience and Scope

CPIP is pan-Canadian pandemic planning guidance for the health sector developed under the guidance of a group of Canadian experts. The primary audiences are the FPT ministries of health together with other ministries that have health responsibilities. While it is anticipated that CPIP's strategic direction and guidance will inform FPT planning in order to support a consistent and coordinated response across jurisdictions, PTs have ultimate responsibility for planning and decision-making within their respective jurisdictions. CPIP also serves as a reference document for other government departments, non-governmental organizations (NGOs) engaged in health issues, and other stakeholders.

While CPIP provides pandemic planning guidance, it does not address business continuity preparedness or overall management of a health emergency. These activities are critical for an effective pandemic response; however they are more appropriately addressed in the emergency plans of individual jurisdictions and organizations. Neither does CPIP address pandemic preparedness and response in the non-health sectors (e.g., community and social services, public safety), although some of its content may be a useful reference.

1.4 Changes in This Version

There have been considerable changes to CPIP since the 2006 version in both format and content.The strategic nature of the information in the main body of the planning guidance has been strengthened and lessons learned from the 2009 pandemic have been incorporated. While the overall pandemic goals remain the same, new objectives have been added along with a set of principles to support the response. These are accompanied by a discussion of ethical considerations pertaining to pandemic preparedness and response, and consideration of the implications of Canada's diversity and the needs of vulnerable persons. Roles and responsibilities for each level of government have been described more explicitly.

The new CPIP outlines a risk management approach to support a flexible and proportionate response. Risk management involves setting the best course of action in an uncertain environment by identifying, assessing, acting on and communicating risks. Information has been added about what is known and what is uncertain about pandemic influenza. The planning assumptions have been updated, and four hypothetical planning scenarios have been developed to illustrate the importance of developing plans and response strategies that are flexible and can

be adapted as circumstances require. CPIP also provides triggers for action that are based on novel virus emergence and pandemic activity in Canada rather than the global World Health Organization (WHO) phases. Finally, content has been updated in each of the specific response areas.

The CPIP technical annexes are being renamed according to their subject (e.g., Surveillance, Vaccine) instead of being named alphabetically. As part of the CPIP renewal process, it is intended that each of the technical annexes will be revised.

2.0 Context for Planning

2.1 Understanding Pandemic Influenza

2.1.1 Influenza and the Origin of Pandemics

While there are four types of influenza virus (A, B, C and D), only influenza A and B viruses cause seasonal outbreaks in humans, and only influenza A viruses have been known to cause pandemics. Aquatic birds are the natural hosts for influenza A viruses, although a wide range of species can be infected and significant disease outbreaks can occur in poultry, pigs and other species. Most of these animal influenza virus strains do not cause disease in humans although occasional human (zoonotic) infections occur, usually through close contact with infected poultry or animals.

Influenza pandemics or worldwide epidemics occur when an influenza A virus to which most humans have little or no immunity acquires the ability to cause sustained human-to-human transmission leading to community-wide outbreaks. Such a virus has the potential to spread rapidly worldwide, causing a pandemic. [1]

These novel viruses may arise through genetic reassortment (a process in which animal and human influenza genes mix together) or genetic mutation (when genes in an animal virus change, allowing the virus to easily infect humans). Pigs can become infected with influenza viruses from different species and act as a “mixing vessel” to facilitate the reassortment of genes from different viruses.

Not all novel influenza viruses evolve into pandemic viruses. Some novel subtypes, like the avian A (H5N1) virus, have caused sporadic human cases on an ongoing basis since 1997 but have not gained the ability to spread easily in humans. As the overall human case fatality rate for A (H5N1) infections has been over 50%, [2] there are concerns about the potential of a high impact human pandemic if this virus gains the capacity to spread easily between people.

2.1.2 Typical Pandemic Characteristics

Historical evidence suggests that influenza pandemics occur three to four times per century. In the last 100 years there were four pandemics separated by intervals of 11 to 41 years. They varied greatly in their impact, as measured by illness and deaths. The 1918-1919 pandemic had a high impact, killing an estimated 30,000 to 50,000 people in Canada and 20 to 50 million people worldwide. The impact of the 1957 and 1968 pandemics was considered moderate, whereas the 2009 pandemic had a lower impact.

Pandemics of the Last 100 Years, subtypes and common names:

1918-1919:	H1N1 “Spanish flu”
1957-1958:	H2N2 “Asian flu”
1968-1969:	H3N2 “Hong Kong flu”

2009:	H1N1 "Influenza A(H1N1) 2009"

While every pandemic is different, some common characteristics can be recognized:

- The pattern of disease is different in pandemics than in seasonal influenza.
- Pandemics may arrive outside of the usual influenza season and typically have more than one wave of illness.
- The total duration of a pandemic is likely to be 12 to 18 months.
- During a pandemic, the new pandemic virus replaces other circulating influenza strains. Afterwards, the pandemic strain becomes part of (and may dominate) the mix of seasonal influenza A viruses.
- During seasonal influenza, most hospitalizations and deaths occur in the elderly and persons with underlying health conditions, whereas, in a pandemic, disproportionately more severe disease and death is seen in young people and in persons without underlying health conditions. [3]
- There is a gradual reversion back to the typical seasonal morbidity and mortality pattern over the decade following the pandemic.

During the 1918-1919 pandemic, 99% of influenza-associated deaths in the United States (US) were in persons under 65 years of age and nearly half of these among previously healthy adults 20-40 years of age. In subsequent pandemics, the proportion of influenza-associated deaths in the US in persons under 65 years of age was 36% (1957-58), and 48% (1968-69). [4] In the 2009 pandemic 70% of reported deaths in Canada were in persons under 65 years of age. [5]

2.1.3 Pandemic Impact

The term “severity” is often used to describe both severity of disease in individuals (clinical severity) and the overall “severity” of a pandemic in a population. In CPIP, the term **severity** is used to describe clinical severity of disease in individuals and **impact** is used to describe the effects of a pandemic on the population.For planning and response purposes, describing the “impact” of a pandemic on the population is a more meaningful approach than talking about its “severity”. It is acknowledged that this usage may vary from the approach of some other authorities. For example, the WHO uses the term “pandemic severity” for what CPIP terms “impact” but the concepts are the same. [6]

Severity refers to clinical severity of disease in an individual (e.g., mild, moderate or severe disease).

Impact refers to the effects of a pandemic on a population (e.g., low, moderate, or high impact).

Pandemics vary in their impact, as do seasonal influenza outbreaks, although usually on a higher scale of magnitude. A low impact pandemic might resemble moderate to severe seasonal influenza outbreaks, although its epidemiological profile would be different in important ways as previously described. In contrast, pandemics of moderate to high impact could result in high rates of illness and death across the country and would severely challenge the health care sector. They could also disrupt the normal functioning of society and put people with limited resources and support systems into a more vulnerable state.

Numerous factors can affect pandemic impact. These are outlined below and described in more detail in Appendix A:

- Viral factors are perhaps the most important. These characteristics of the virus itself are usually described as transmissibility (ability to spread) and virulence or clinical severity (the ability to cause severe disease). Transmissibility can be defined in terms of both the extent and the speed of spread and it can vary by season and setting.

- Factors affecting population vulnerability include pre-existing population immunity, the presence of underlying health conditions, or unexpected new risk factors for severe disease. Impact may be increased in vulnerable populations, including among Indigenous peoples, or settings such as remote communities, homeless shelters and overcrowded housing.
- Response factors include the effectiveness of interventions (e.g., public health measures, vaccine, and antiviral medications), the health care system response (e.g., access, surge capacity), and risk communications, along with the extent of public adoption of desired behaviours and social mobilization.

The impacts of a pandemic in psychosocial terms may be acute in the short term but can also undermine the long-term psychological well-being of the population. Psychosocial issues are not only experienced by those who become ill; distress permeates through the family and the community (e.g. financial stress due to economic downturns, caregiver burnout, occupational stresses, stigma/social exclusion).

The range of issues associated with psychosocial planning is broad involving all levels of government and multiple planning partners, including humanitarian actors such as community-based organizations, government authorities and NGOs and are closely aligned with the practice of risk communication [7].

2.2 Uncertainties and Unpredictability

Influenza is unpredictable - every influenza season and every pandemic is different. These uncertainties make pandemic planning challenging and highlight the need for flexibility and adaptability. Some of the major unknown areas about the next pandemic are the following:

- When the next pandemic will occur - although historically pandemics have occurred three to four times per century, there is no predictable interval. It should not be assumed that the 2009 pandemic has provided a respite during which preparedness efforts can be relaxed.
- Where it will emerge - while most seasonal influenza strains emerge in East/Southeast Asia, [8] the same is not true for pandemic influenza; the 2009 pandemic emerged in Mexico. An influenza pandemic could emerge anywhere in the world, and there may be very little lead time before Canada is extensively involved.
- What the nature of spread will be - pandemics often first arrive outside the usual influenza season (e.g., in late spring or summer) and typically have more than one wave of infection. However, this is not true in all circumstances or in all areas. A small first wave is often followed by a larger second wave, but the relative size of pandemic waves may vary. The speed of spread may also vary - pandemic waves can be intense or more spread-out over time. An intense wave would put more stress on the health care system.
- What its characteristics will be - the basic characteristics of the next pandemic virus are unknown, including its antigenic type (e.g., H2, H5, H7), its transmissibility and virulence, and the age groups and clinical groups most affected.
- What its impact will be - the last four pandemics demonstrated that population impact can vary from low to high and is not the same in all populations or settings. It is important to consider all possibilities and make plans adaptable for different circumstances. This will help ensure that the response is proportional to the evolution of the pandemic in any specific community.
- What effect interventions will have - typical seasonal influenza interventions are expected to be effective during the pandemic. However, the novel virus could be resistant to antiviral medications and/or pandemic vaccine production could be delayed or unsuccessful. The extent of vaccine uptake and adoption of public health measures is also unknown. Furthermore, interventions could have unintended consequences.

2.3 Lessons Learned from the 2009 Pandemic

There were many important epidemiological observations from the 2009 pandemic to take into account in future planning and response. These include the speed with which cases and sporadic outbreaks appeared in Canada after the novel virus was first detected and the early involvement of some remote and isolated communities, with severe disease in some First Nations communities. There was considerable variation in the timing and intensity of pandemic waves, especially the first wave, across the country. Although the symptoms were similar, age groups affected and risk conditions varied from seasonal influenza. Greater impact was seen in pregnant women and Indigenous peoples, and persons with morbid obesity were newly recognized as being at high risk for complications. For the duration of the pandemic, seasonal influenza strains were replaced by the pandemic strain and as with previous pandemics, it was not certain whether this single A strain dominance would continue in the 2010/2011 influenza season, A (H3N2) and B strains began to re-circulate and the pandemic virus became the seasonal A (H1N1) strain.

A number of challenges were identified in the national response. Surveillance demands were very heavy from the start, and were accentuated by the lack of linked information systems in some jurisdictions, unclear protocols for sharing information, and limited capacity for epidemiological analysis. The process for release of the National Antiviral Stockpile (NAS) was uncertain. There was high demand for critical care and ventilators for affected children and adults. Preparation and timely approval of concise national guidelines was difficult. The pandemic immunization program faced challenges with uncertain timelines for vaccine delivery, prioritization of vaccine supply, logistics of local campaigns and communication of changing recommendations.

On the positive side, previous planning processes and relationship-building led to unprecedented FPT collaboration and many successful stakeholder engagement efforts. Existing surveillance systems, like FluWatch, and ready-to-use hand hygiene and respiratory etiquette campaigns were valuable. Mathematical modeling was successfully used to support decision-making in some areas (e.g., recommendations for vaccine prioritization) and it was recognized that a number of other areas would benefit from modeling (e.g. predicting pandemic impact).

Following the pandemic, the Government of Canada (GC) [9] and most PT governments conducted lessons learned reviews. In addition, the Standing Senate Committee on Social Affairs, Science and Technology held extensive hearings on the response. [10] Some common themes emerging from these reports and recommendations were identified to improve preparedness, such as:

- streamlined FPT governance structure and clarification of roles and responsibilities;
- improved scalability and adaptability of response, with triggers to activate and deactivate specific responses while taking into account the variable impact and timing of the pandemic in different geographic regions;
- development of integrated electronic information management systems;
- strengthened surveillance systems and epidemiological capacity;
- collaborative processes to develop and strengthen guidance documents for health care workers (HCW) and other stakeholders to establish timely availability, accessibility, consistency and cultural sensitivity of messages;
- strategies to communicate risk, uncertainty and changing information;
- active participation of all stakeholders in pandemic preparedness and response;
- strengthened linkages with primary care and other front-line service providers;
- development of mechanisms for rapid funding and research priority-setting, multi-jurisdictional studies and centralized ethics approval for multi-centre studies;
- mechanisms to integrate new research findings into evidence-informed practice; and
- regular and rigorous testing of plans at all levels.

2.4 Understanding Canada's Diversity

Canada's geographic features and population diversity can create challenges in mounting an effective response to a public health emergency. Canada is a huge country geographically with communities that range in size from large cities to small rural and remote settlements. The proportion of people living in rural areas in Canada (18.9%) is low in comparison to other developed countries and is steadily declining. The proportion of the rural population, however, varies greatly (from 14% to 53%) from one province or territory to another. It is lowest in British Columbia and Ontario and is highest in the Atlantic provinces and the territories. [11]

Canada is diverse in terms of language, religious beliefs, ethnicity, culture and lifestyle. Canada's Indigenous peoples make up almost 4% of the population, the second highest percentage in the world after New Zealand. [12] While many Indigenous peoples live in remote and isolated communities in the North, about half live in urban areas. The median age of Canada's Indigenous peoples is considerably younger than that of non-Indigenous peoples (27 years compared with 40 years respectively). [13]

The proportion of foreign-born people in Canada is one of the highest in the world at 20%, [14] most of whom settle in large cities. Toronto and Vancouver now have over 40% visible minority populations and Montreal has 16%. [15] In addition there are many temporary residents, such as foreign workers and foreign students.

The needs of remote and isolated communities may be greater than other communities because of geographic isolation and health, social, environmental, economic and cultural considerations. These may affect the baseline health status and thus increase the vulnerability of their residents. In addition, some remote and isolated communities lack basic amenities, such as household access to running water, that are assumed to be present when public guidance like hand hygiene is issued. It is important to consider these factors, along with limited access to health care and transportation challenges, when planning for all aspects of the pandemic response in remote and isolated communities. Similar concerns may affect urban marginalized or vulnerable populations.

There are individuals within all jurisdictions whose needs are not fully addressed by traditional services or who cannot comfortably or safely access and use standard resources. Examples of these vulnerable persons include, but are not limited to, individuals who are:

- physically or mentally disabled (e.g., visually or hearing impaired, mobility limitations, cognitive disorders);
- limited or non-English or French speaking;
- low literacy;
- geographically, culturally or socially isolated;
- low income;
- medically or chemically dependent;
- homeless or street-involved;
- housebound or frail seniors; and
- new immigrants and refugees. [16]

It may not be a single one of these conditions that determines the degree of vulnerability, but rather a combination of them under certain circumstances [17].

Studies indicate that there is a social gradient of risk during influenza pandemics, based on social vulnerabilities that are likely to lead to increased exposure to infection, risk of basic human needs not being met, insufficient support and/or inadequate treatment. [18] Vulnerable populations might become more marginalized if pandemic health services are streamlined into standard approaches to reach the general population.

Within the nationally coordinated pandemic response it is important to allow sufficient local flexibility to address the unique needs of vulnerable populations. Detailed influenza-specific planning guidance has been developed for vulnerable populations in Canada. [19, 20] These referenced documents should be useful for FPT and regional/local planners.

Responsibility for planning for vulnerable populations is often unclear and although public health is typically involved, inclusion of all relevant stakeholders is important for comprehensive planning and buy-in. It is important for planners to address the unique needs of their jurisdiction. This begins with identifying populations and settings associated with increased risk of illness or severe outcomes from pandemic influenza along with persons who might need tailored prevention and care services during a pandemic. Specific planning considerations include information needs (e.g., language, cultural style and methods of dissemination); access to assessment, treatment (including antiviral medications) and convalescence support; access to vaccine; and need for support for activities of daily living.

2.5 Ethical Considerations

This section summarizes the more important ethical considerations in pandemic planning but is not intended to be an actual ethical framework. Ethical considerations are also addressed more specifically in various CPIP annexes with supporting tools and frameworks where available.

In Canada, ethical considerations are increasingly taken into account in the development of health policy. Ethical analysis helps to identify the ethical issues and determine how to do the right thing in a fair, just and transparent way. Many of the issues encountered in pandemic preparedness and response involve balancing rights, interests and values. Examples include decisions over resource allocation; prioritization guidelines for pandemic vaccine and antiviral medications; adoption of public health measures that may restrict personal freedom; roles and obligations of HCWs and persons providing medical first response, as well as their employers; the potential need for triage in the provision of critical care; and responsibilities to the global community. [21]

The application of ethical reasoning to pandemic preparedness and response begins with identifying and prioritizing the ethical questions in the issue under consideration. Analysis should include reflection on the ethical considerations associated with the options, taking into account the societal versus individual interests and values that are at stake. Ethical tensions are inevitable. When weighing the options, it is important to be guided by the Canadian pandemic goals.

As pandemic planning initiatives fall within the domain of public health, they are guided by a code of ethics that is distinct from traditional clinical ethics. [22] Whereas clinical ethics focuses on the health and interests of individuals, public health ethics focuses on the health and interests of a population. When a health risk like a pandemic affects a population, public health ethics predominates, and a higher value is placed on collective interests.

In practical terms, this means there should be an emphasis placed on trust and solidarity. Successful public health activities require relationship-building and can contribute to creating and maintaining trust between individuals, populations and health authorities. Solidarity is the notion that we are all part of a greater whole, whether an organization, a community, nation or the globe. Another important consideration is reciprocity, meaning that those who face disproportionate burdens in their duty to protect the public (e.g., HCWs and other workers who are functioning in a health care capacity, for example police or fire personnel who are providing medical first response) are supported by society, and that to the extent possible those burdens are minimized.

The concept of stewardship is also closely related to trust. Stewardship refers to the responsible planning and management of something entrusted to one's care, along with making decisions responsibly and acting with integrity and accountability. Trust, stewardship and the proper building of relationships also mean that the power conferred to government and health authorities will not be abused. For example, if restrictions are deemed essential for proper risk management, they must be effective and proportional to the threat, meaning that they should be imposed only to the extent necessary to prevent foreseeable harm. These restrictions should also be counterbalanced with supports to minimize the burden on those individuals affected.

The concepts of equity and fairness are very important to Canadians. In a pandemic context, they lead to a number of considerations. As much as possible, benefits and risks should be fairly distributed through the population. This may be difficult, however, in some circumstances, such as a pandemic that differentially affects certain populations or a very severe pandemic if resources are in short supply. Decisions should take health inequities into account and try to minimize them, rather than make them worse. Access to necessary health care may be restricted in a health crisis; however, available resources (e.g., vaccine and antiviral medications) should be distributed in a fair and equitable way. What will constitute fair and equitable distribution will be context dependent. Therefore the transparency and reasonableness of decision-making processes are important.

Good decision-making processes are also essential for ethical decision-making. They involve the following: [23], [24]

- openness and transparency - the process is open for scrutiny, and information about the basis for decisions and when and by whom they were made is publicly accessible;
- accountability - being answerable for decisions;
- inclusiveness - stakeholders are consulted, views are taken into account, and any disproportionate impact on particular groups is considered; and
- reasonableness - decisions should not be arbitrary but rather be rational, proportional to the threat, evidence-informed and practical.

2.6 Legal Considerations

The legal considerations that arise in the context of pandemic preparedness and response are varied and complex. International laws as well as FPT legislation will be relied upon during both the preparedness and responses phases of a pandemic.

2.6.1 International Requirements

International Health Regulations (2005)

The current International Health Regulations (2005) [IHR (2005)] came into force in 2007. They provide a framework for monitoring and enhancing global public health capacity and international communication regarding potential public health emergencies of international concern (PHEIC). The aim of the IHR (2005) is to prevent the international spread of disease while limiting interference with international traffic and trade. The IHR (2005) also establish a more effective and transparent process for WHO and its Member States (including Canada) who are States Parties to the Regulations, to follow when determining and responding to a PHEIC. Most importantly, they broaden the scope of international collaboration to include any existing, re-emerging or new disease that could represent an international threat.

The IHR (2005) include obligations for States Parties to:

- develop core capacity for surveillance and response;
- establish a national focal point (NFP) as the contact point for WHO on all IHR matters; and

- notify WHO of all potential PHEIC within specified time frames.

In order for Canada to meet the IHR (2005) requirements, all levels of government must collaborate. In Canada, PTs use established protocols to report influenza infections of international concern to the Public Health Agency of Canada (PHAC), which is Canada's NFP. After an initial assessment if notification is required, PHAC communicates with the WHO. Reportable influenza-related events include cases of human influenza caused by a new subtype as well as cases having potential international public health implications that meet the notification criteria established under Annex 2 of the IHR (2005). WHO then re-assesses the event to determine whether the event constitutes an actual PHEIC. The first PHEIC declared by the WHO under the IHR (2005) was the influenza A (H1N1) pandemic in 2009.

Pandemic Influenza Preparedness Framework

The Pandemic Influenza Preparedness Framework (PIP Framework) for the sharing of influenza viruses and access to vaccines and other benefits was adopted by the World Health Assembly in 2011. The PIP Framework aims to improve the sharing of influenza viruses with pandemic potential and to achieve more predictable, efficient and equitable access for countries in need of life-saving vaccines and medicines during future pandemics.

Under the Framework, Member States, including Canada, are responsible for:

- ensuring the timely sharing of influenza viruses with human pandemic potential with the Global Influenza Surveillance and Response System (GISRS);
- contributing to the pandemic influenza benefit-sharing system; and
- continuing to support the GISRS.

2.6.2 Federal Legislation

The Emergency Management Act (2007), section 6(1), makes each minister accountable to Parliament for a government institution responsible to identify the risks that are within or related to his or her area of responsibility and prepare emergency management and response plans with respect to those risks; to maintain, test and implement those plans; and to conduct exercises and training in relation to them.

In accordance with responsibilities under the Act, the federal Minister of Health is primarily responsible for developing, testing and maintaining mandate-specific emergency plans for the federal Health Portfolio, which includes Health Canada (HC) and PHAC. These emergency plans outline the federal response to national public health threats or events such as major disease outbreaks (including an influenza pandemic), and to the health effects of natural disasters or major chemical, biological, radiological, nuclear and explosive (CBRNE) events.

Furthermore, the Quarantine Act (2005) strives to prevent the introduction and spread of communicable diseases into and out of Canada by providing the Minister of Health with the authority, including enforcement mechanisms, to take public health measures as required. Pandemic Influenza Type A is listed in the Act's Schedule of Diseases.

2.6.3 Provincial/Territorial Legislation

Health emergency management in the PTs in Canada is governed by legislation specific to each jurisdiction. This legislation requires the PT governments to have comprehensive emergency plans respecting preparation for, response to and recovery from emergencies and disasters, including those with potential impact on critical infrastructure. Important health emergency management powers are also found in public health legislation.

The 2009 pandemic provided an opportunity to identify problems or gaps in existing legislation (including public health legislation) that should be addressed in order to respond more effectively to a future pandemic. An effective response requires an authority to establish appropriate leadership for a coordinated response, along with

authority for PT and local public health officials to implement appropriate control measures. Planners should ensure that they will have authority to mount an effective response whether or not an emergency is officially declared.

3.0 Canada's Approach to Pandemic Influenza

3.1 Goals and Objectives

Goals serve an important purpose in guiding preparedness and response, and in prioritizing the use of resources if necessary. Canada's goals for pandemic preparedness and response are:

> First, to minimize serious illness and overall deaths, and second to minimize societal disruption among Canadians as a result of an influenza pandemic.

These national goals were originally presented in the Canadian Pandemic Influenza Plan for the Health Sector, which was endorsed by FPT Ministers of Health in 2004. The goals, and their sequence, had undergone extensive deliberation by FPT pandemic planners and other stakeholders. A survey carried out as part of the Canadian Program of Research on Ethics in a Pandemic (CanPREP) found that over 90% of participants agreed that the most important goal of pandemic influenza preparations was saving lives. [25] During the 2009 pandemic, the pandemic goals were invaluable in guiding aspects of the response.

The supporting objectives for the health sector are as follows:

1. **Minimize serious illness and overall deaths by**
    - reducing the spread of infection through promotion of individual and community actions;
    - protecting the population through provision of pandemic vaccine and implementation of other public health measures; and
    - providing treatment and support for large numbers of persons while maintaining other essential health care.
2. **Minimize societal disruption by**
    - supporting the continuity of health care and other essential services;
    - supporting the continuation of day-to-day activities as much as possible and promoting a return to normal community functioning as soon as possible;
    - maintaining trust and confidence through
        - support of evidence-informed decision-making by collection, analysis and sharing of surveillance and other scientific information; and
        - communication of appropriate and timely advice to decision-makers, health professionals and the public; and
    - supporting a coordinated response by working collaboratively with all levels of government and stakeholders.

3.2 Guiding Principles and Approaches

The following principles underpin Canadian pandemic preparedness and response activities and decision-making:

- Collaboration - all levels of government and health care stakeholders need to work in partnership to produce an effective and coordinated response. This implies adopting consistent and collaborative approaches to

planning, response and recovery, and having an effective FPT decision-making process. It also implies involvement of stakeholders in these steps.

- Evidence-informed decision-making - decisions should be based on the best available evidence to the extent possible. It is recognized that other factors also enter into decision-making, such as legal and institutional constraints, values, costs and availability of resources. [26]
- Proportionality - the response to a pandemic should be appropriate to the level of the threat.
- Flexibility - actions taken should be tailored to the situation and subject to change as new information becomes available. The pan-Canadian approach should be consistent, although patterns of spread may mean that regional and local jurisdictions will require flexibility in terms of the scale and timing of their response.

In addition to these main guiding principles, Canadian pandemic planning and response activities are also guided by:

- A precautionary/protective approach - this approach is particularly applicable in the early stages of a pandemic when evidence-informed decision-making is not possible due to lack of data and the uncertainty of an evolving event. This means taking timely and reasonable preventive action, proportional to the threat and evidence-informed to the extent possible. This does not mean that in the absence of evidence, all actions must be taken; rather, it means that as emerging evidence reduces uncertainty, evidence-informed actions may supersede those precautionary measures taken at the outset.
- Use of established practices and systems to the extent possible - it is extremely difficult to implement new ways to do things during an emergency. Effective seasonal influenza responses support a strong pandemic response, as well-practised strategies and processes can be rapidly ramped up to manage the pandemic.
- Ethical decision-making - ethical principles and societal values should be explicit and embedded in all decision-making, including the processes used to reach decisions. It is especially important to ensure that all actions respect ethical guidelines tailored to the concerns of public health, while respecting the rights of individuals as much as possible.

3.3 Coordination of National Preparedness and Response

The global nature of a pandemic requires a response that differs from many other types of emergency. Traditionally, the responsibility to deal with an emergency is placed first on the individual/household to manage the effects of the emergency as it affects them, and then on successive levels of government as the resources and expertise of each are needed. Public Safety Canada is responsible for coordinating the whole of government response when the federal government is involved in the response to an emergency. Within the PTs a similar function is performed by the appropriate ministry or emergency measures organization.

In a pandemic situation, a pan-Canadian whole-of-government response is required so that all potential resources can be applied to minimizing the pandemic's negative health, social and economic impacts. Pandemic plans should be aligned across jurisdictions to facilitate successful FPT collaboration during a pandemic.

The following sections provide a high-level overview of FPT health emergency planning and response relevant to pandemics.

3.3.1 Emergency Management Frameworks and Plans

The GC has in place a coordinated system of federal emergency management frameworks, systems and emergency response plans, many of which can be accessed at Public Safety Canada's web site. These plans are based on the four components of the emergency management continuum (prevention and mitigation,

preparedness, response and recovery) and they use an all-hazards approach. Emergency response plans for the federal Health Portfolio are part of this GC system.

The FPT health sector also has a system of frameworks and emergency response plans parallel to those of the federal health sector, that are comprehensive and flexible enough to address any type of national health emergency. The development and maintenance of some of these documents, including CPIP, is overseen by the PHN.

The federal and FPT emergency management plans are supported by various operational annexes and guidance documents. These are nested under the generic all-hazards emergency response plans and deal with more specific threats.

3.3.2 Pan-Canadian Coordination of the Pandemic Health Sector Response

Because a pandemic is a significant health event, the FPT ministries of health have the primary mandate for the health sector response in their respective jurisdiction and act as advisor for other sectors on health issues.

At the federal level, the Centre for Emergency Preparedness and Response (CEPR) at PHAC is the Health Portfolio's focal point for coordinating and providing a wide range of emergency management services with other federal departments, PT governments, NGOs and the private sector. CEPR is responsible for the Health Portfolio Operations Centre (HPOC) in Ottawa and its linkages to other operational centres at the FPT level.

Coordination of the FPT ***health sector response*** to a pandemic will follow the governance structure outlined in the FPT Public Health Response Plan for Biological Events (FPT-PHRPBE). The FPT-PHRPBE is complementary to and used in conjunction with existing jurisdictional planning and response systems.

The FPT-PHRPBE is intended to bridge the gap between PT public health response plans and federal health response plans by providing a single, common overarching governance framework for the FPT health sector that can be applied, in full or in part, during a significant public health event requiring a coordinated FPT response, such as an influenza pandemic.

The FPT-PHRPBE defines a flexible FPT governance mechanism that identifies escalation considerations and response levels for a scalable response, and to improve effective engagement amongst public health, health care delivery and health emergency management authorities during a coordinated FPT response. This will ensure that at the time of a response, notification processes and inter-jurisdictional information-sharing will be enhanced; public and professional communication will be addressed; and advance planning and decision-making between and amongst multiple jurisdictions will be facilitated.

Finally, as the effects of a pandemic are not exclusive to the health system, it is critical for FPT governments and emergency management partners to use a common approach in responding to a pandemic. Emergency social services (e.g. non-medical services considered essential for the immediate physical and social well-being of people affected by disasters) should be coordinated within the broader PT response and aligned with health system activities.

3.3.3 North American Plan for Animal and Pandemic Influenza

The North American Plan for Animal and Pandemic Influenza (NAPAPI) outlines how Canada, Mexico and the US intend to work together to combat an outbreak of animal influenza or an influenza pandemic in North America. The NAPAPI addresses both animal and public health issues, including early notification and surveillance, joint outbreak investigation, epidemiology, laboratory practices, medical countermeasures (e.g., vaccine and antiviral

medications), personnel sharing and public health measures. It also addresses border and transportation issues. While the NAPAPI is not legally binding, it reflects strong commitments by the countries involved to work collaboratively.

3.4 Pandemic Roles and Responsibilities

Collaboration in pandemic planning and response is strengthened by having clearly defined and well-understood roles and responsibilities. While this section focuses on government responsibilities, it is acknowledged that other partners also have important roles and responsibilities in a pandemic. These partners include the non-health sector, private sector, NGOs, municipalities and local/regional health authorities, and international organizations. Similarly, members of the general public bear responsibility for keeping themselves informed and for cooperating with measures to reduce the spread of illness.

3.4.1 World Health Organization

WHO's pandemic roles and responsibilities are outlined in the WHO pandemic influenza risk management guidance document and include: [27]

- coordination of the international response under the IHR (2005), including conducting global risk assessments;
- communication of the global situation using the global pandemic phases;
- declaration of a PHEIC and pandemic as required under the IHR;
- provision of information and support to affected States Parties;
- selection of the pandemic vaccine strain and determination of when to move from seasonal to pandemic vaccine production; and
- provision of oversight and support for implementation of the PIP Framework.

3.4.2 Canada - FPT Governments

Responsibility for health services in Canada is shared across all levels of government. High-level roles and responsibilities for FPT governments are outlined below; more detailed information about roles and responsibilities for specific response components can be found in the CPIP annexes. It is recognized that responsibilities for federal populations, which are summarized at the end of this section, are complex and evolving.

A. International aspects

International aspects of influenza management and liaison are a federal responsibility.

The federal government is responsible for:

- acting as the national focal point for the WHO on all IHR (2005) matters and managing all international aspects of pandemic preparedness and response;
- providing travel health notices and other health related information relevant to international travel; and
- exercising powers under the Quarantine Act to protect public health by taking comprehensive measures to help prevent the introduction and spread of communicable diseases in Canada. Such measures may include, but are not limited to, the screening, examining and detaining of arriving and departing international travellers, conveyances (e.g., airplanes and cruise ships) and their goods and cargo.

B. Collaboration, communication, information sharing and policy recommendations

While PT governments are responsible for communications plans and messaging within their jurisdictions, a coordinated pan-Canadian pandemic response requires collective infrastructures, response capacities and coordinated activities.

The federal government is responsible for:

- ensuring that risk assessments for novel and pandemic viruses are prepared and communicated as required; and
- facilitating the coordination of the overall pan-Canadian response to a pandemic.

FPT governments will work collaboratively to:

- coordinate and support the process required for development and periodic updating of CPIP and its annexes, for which PHAC acts as the custodian;
- assess capacity gaps for a pan-Canadian response and address gaps as necessary;
- align federal pandemic plans for federal populations, (see Section F for federal populations), with PT plans, where relevant;
- assess surveillance capacity, standards and protocols and modify as necessary;
- assess laboratory capacity, standards and protocols and modify as necessary;
- establish and support pan-Canadian policies and recommendations on the use of antiviral medications and vaccine during a pandemic;
- develop and implement public health guidance;
- ensure development and dissemination of clinical care guidance;
- develop a pan-Canadian communication strategy that reflects Canadian linguistic, literacy and cultural characteristics and allows for the alignment of messaging by FPT jurisdictions where appropriate;
- establish protocols for the sharing of relevant information, including but not limited to FPT plans and drafts; surveillance information; jurisdictional communications, strategies and messaging; and pandemic response interventions and impacts; and
- identify and address rapid research response priorities and leverage their respective research undertakings.

C. Antiviral medications and influenza vaccine

The federal government is responsible for:

- providing regulatory authorization to market antiviral medications and influenza vaccines;
- acting as the focal point for vaccine manufacturers and international regulatory collaboration;
- providing regulatory authorization to conduct clinical trials;
- negotiating with manufacturers and establishing contracts for the FPT purchase of antiviral medications and vaccine for pandemic purposes;
- national monitoring of adverse reactions to antiviral medications and vaccines; and
- providing antiviral medications and vaccine to those federal populations not covered by arrangements for PT provision.

PT governments are responsible for maintenance, monitoring, distribution and administration of antiviral medications and vaccine in their respective jurisdictions. They will work collaboratively to:

- provide antiviral medications and, when available, vaccine to recommended populations;
- share information regarding the distribution and use of antiviral medications and vaccines in their respective jurisdictions; and
- monitor and report adverse vaccine reactions.

The PT governments are also responsible for the distribution of vaccines and antiviral medications to most federal populations, but this varies by federal population and jurisdiction (see section F on federal populations).

FPT governments will work collaboratively to develop strategies to mitigate the effects of insufficient or delayed antiviral drug and/or vaccine supply, should such a situation arise.

D. Health sector preparedness and response

Health sector preparedness and response remains the responsibility of each jurisdiction. In some jurisdictions responsibility for emergency social services also falls to the health sector.

PT governments are responsible for:

- ensuring that PT pandemic plans (or all-hazards plans depending on the jurisdiction) are developed, tested and periodically updated;
- considering the content and intent of CPIP in the development of their PT jurisdictional plans;
- communicating and engaging with the general public, media and stakeholder groups about their respective plans; and
- activating PT pandemic or all-hazards plans.

The federal government has similar responsibilities for federal departments within the health sector and for federal populations in collaboration with the PTs (see section F on federal populations).

E. Health care provision

The provision of health care is an essential component of pandemic response and is primarily a PT responsibility.

PT governments are responsible for:

- developing plans to increase surge capacity in order to care for affected persons in their jurisdiction;
- providing health care services for persons within their jurisdiction, including for federal populations while leveraging agreements that are in place (federal populations and federal responsibility are covered in the next section);
- developing and maintaining memoranda of understanding and protocols as needed, preferably before the pandemic, to facilitate interprovincial/territorial movement of patients and licensed health care professionals during a pandemic and other aspects of mutual aid;
- developing, as necessary, a strategy for collecting and monitoring data on health care service use;
- ensuring the provision of medications, supplies and equipment required for provision of pandemic health care services; and
- working collaboratively to establish protocols and guidelines for prioritizing health care services during times of high service demand and staff or supply shortages in the respective jurisdiction.

The federal government is responsible for:

- ensuring the provision of health services, medications, supplies and equipment for specified federal populations/employees who normally access federally operated health care services;
- facilitating access to surge capacity, including from federal programs, employees and resources, to support PT responses if required;
- mobilizing medical supplies in the National Emergency Strategic Stockpile (NESS) as surge capacity to support PT responses; and
- facilitating the acquisition of extra medical supplies through Public Services and Procurement Canada and other federal agencies as appropriate.

F. Federal populations

Federal populations are those populations for which the federal government either provides health care and benefits, goods and/or services or reimburses the cost of providing health care and benefits. With the exception of the Canadian Forces which has its own distinct health care system for active members, the needs of federal populations must be integrated into PT pandemic planning activities in order to establish a comprehensive and coordinated pandemic response.

Federal populations include the following:

- First Nations on-reserve, inclusive of First Nations who have assumed responsibility for health services under a transfer agreement;
- active members of Canadian Forces;
- federal offenders or inmates of federal penitentiaries;
- refugee claimants, protected persons, detainees under the Immigration and Refugee Protection Act, rejected refugee claimants, and other specified populations; and
- Canada-based staff at missions abroad.

The federal government is responsible for:

- supporting the provision and distribution of medications, supplies and equipment to federal populations, as noted in the list above, through existing FPT distribution and administration systems.

The federal government will work collaboratively with PT governments to:

- ensure that access to pandemic health services for all federal populations is available on the same basis as is provided to other residents of Canada, while leveraging agreements that are in place. This involves but is not limited to access to antiviral medications, influenza vaccines and supplies needed for provision of pandemic health care services; and
- facilitate the coordination of federal planning for federal populations with PT pandemic plans.

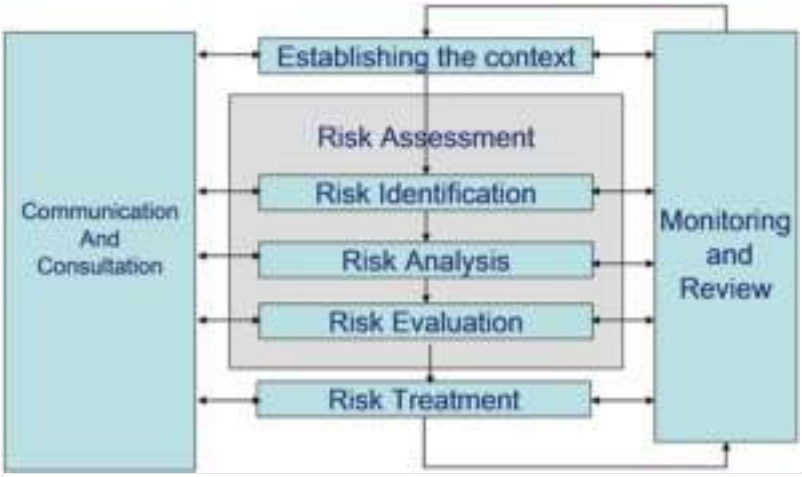
3.5 Risk Management Approach

3.5.1 Overview

Risk management is a systematic approach to setting the best course of action in an uncertain environment by identifying, assessing, acting on and communicating risks. A risk management approach provides a useful framework for addressing the uncertainties inherent in pandemic planning and response. Risk management supports the CPIP planning principles of evidence-informed decision-making, proportionality, and flexibility; and a precautionary/protective approach when there is uncertainty early in an event.

Figure 1 provides a graphic overview of the risk management process as outlined in ISO 31000, the international standard for risk management. The individual steps involved in risk management are then briefly described.

Figure 1 - ISO 31000 Risk Management Process [28]



▶ Figure 1 - ISO 31000 Risk Management Process - Text Equivalent

Risk assessment is a central component of risk management. Its purpose is to provide evidence-informed information and analyses for making informed decisions on how to treat particular risks and select between options. There are three parts to risk assessment:

- Risk identification involves identifying what might happen, or what situations might exist that could affect achievement of the objectives of the organization or system.
- Risk analysis involves analysing the risks in terms of their probability and potential impact (who is affected and to what extent). This analysis helps identify the planning considerations and options for each component of the response. The analysis should also assess the public's perception of risk and how it could influence the risk management response, so that communications strategies and messaging can be tailored appropriately.
- Risk evaluation involves determining the significance of the level and type of risk in order to make decisions about future actions. Ethical, legal, financial and other considerations are also inputs to the decisions. Decisions may include the need and priorities for treatment, whether an activity should be undertaken or which of a number of paths should be followed.

Risk treatment follows risk assessment and involves identifying and recommending risk treatment options, i.e. options for management or control. Risk treatment options should include steps that need to be taken in advance, as well as potential actions at the time of the pandemic.

Communication and consultation are also integral parts of the risk management process. Effective communication with stakeholders should facilitate adequate understanding of the risk management decision-making process, ensure that the process is transparent and help people to make informed decisions. A risk communications plan should be developed at an early stage.

Monitoring and review are important for assessing factors that could change over time and for documenting effectiveness of interventions. Such reviews should lead to periodic updates of the risk assessment.

3.5.2 Risk Management Considerations in Pandemic Planning and Response

Given the large number of variables that are involved in influenza pandemic planning, comprehensive risk management is challenging. The four pandemic planning scenarios described in section 3.7 can assist with risk identification by providing a starting point to think through the risks that would be associated with pandemics of varying impact and their implications.

It is also worthwhile to anticipate key decisions that will need to be taken during the pandemic to help guide the development and analysis of options. It is also worthwhile to clarify ahead of time and to the extent possible what level(s) of government should be involved with which types of decision when the time comes. Examples of these key decisions are as follows:

- what is the scale of the response;
- whether (and when) to escalate or de-escalate the response;
- when, what and how to communicate with the public;
- what amount of vaccine and the formulation(s) to order;
- how vaccine use should be prioritized;
- what public health interventions should be used, when and within which populations, and whether they need to be adjusted over time;
- what influenza testing and treatment strategies to recommend and whether they need to be adjusted over time; and
- what supplementary assessment and treatment services might be needed and, if necessary, when they should be started and stopped.

Anticipating key decisions should be accompanied by identification of the types and sources of information required for decision-making. Establishing robust surveillance for seasonal influenza establishes baselines, develops capacity and provides a platform for escalation during the pandemic.

Anticipating key decisions should also lead to development of relevant options for risk treatment. From a pandemic preparedness perspective, examples of risk treatment include continuity of operations planning; establishment of stockpiles for antiviral medications and other key supplies; development of advance contracts for pandemic vaccine; strengthening influenza surveillance systems, diagnostic and analytical capacity; establishment of protocols for pandemic research; and establishment of communications networks to plan effective and coordinated risk communications strategies.

When a pandemic occurs, planning scenarios are replaced by a real event and response activities will be guided by the available evidence. During the initial stages, little may be known about the likely pandemic impact or the populations most at risk. Many decisions will have to be made before solid information is available and then adjusted, if necessary, as more becomes known, keeping in mind that it is often difficult to scale back a response. As the evidence emerges over time, understanding of the situation will continue to change as new information becomes available and will always be incomplete. A risk management approach will be used throughout the response by all responders. Risk assessments will provide key input into FPT decision-making by identifying what is known at that point in time, what might occur and when, and the major areas of uncertainty.

PHAC will facilitate development of timely and credible risk assessments to support FPT decision-making. These formal risk assessments will be conducted at the start of the pandemic to inform the initial response and then periodically as new information emerges (e.g., at the end of a pandemic wave). Risk assessments will address key information needs, including viral characteristics, the anticipated or experienced impact on the health care system and community, age and risk groups most affected, occurrence of antiviral resistance and estimated effectiveness of control measures. As the pandemic progresses, there will be questions about likely occurrence of more pandemic waves, whether new risk factors are emerging and whether the response should be escalated or de-escalated. Appendix B identifies relevant considerations for initial and ongoing pandemic risk assessments and identifies potential sources for the supporting information.

3.6 Planning Assumptions

This section on planning assumptions and section 3.7 on pandemic planning scenarios describe two important tools for pandemic planning. These tools provide distinct but complementary approaches.

Identifying planning assumptions is a way to deal with uncertainty. Assumptions provide a useful framework for planning but should not be regarded as predictions. While planning assumptions are rooted in evidence to the extent possible, [29], [30] they are basically educated guesses. As the pandemic unfolds, emerging evidence is used to guide the response. Informing the planning assumptions identified below is the WHO's Pandemic influenza risk management interim guidance (2013), the UK's Scientific summary of pandemic influenza & its mitigation (2011) and discussions from the Canadian Pandemic Influenza Preparedness Planning Assumptions Workshop held in 2011.

3.6.1 Origin and Timing

- The next pandemic could emerge anywhere in the world and at any time of year.
- There may be no lead time before the novel virus reaches Canada.
- The first peak of illness in a geographic area within Canada could occur within weeks of first detection of the novel virus in that area. The first peak in mortality is expected to be several weeks after the peak in illness.

3.6.2 Transmission

- The pandemic virus will behave like seasonal influenza viruses in significant ways:
  - incubation period - is expected to last from one to three days;
  - period of communicability - adults are infectious from 24 hours before and up to five days from the onset of symptoms, and children may be infectious for up to seven days. Longer periods have been found, especially in persons with immune compromising conditions;
  - methods of transmission - mainly by large droplet and contact (direct and indirect) routes; the role of airborne transmission is unclear.
- Transmission is expected to be relatively lower in spring and summer than in fall and winter (the general pattern of transmission in temperate countries).
- Transmission is possible from asymptomatic persons but is greater when symptoms, such as coughing, are present and viral shedding is high (i.e., early in the symptomatic period).

3.6.3 Pandemic Epidemiology

- Most communities will experience two or more pandemic waves of different magnitudes. In any locality, the length of each wave will be from several weeks to a few months but may vary by community.
- There will be geographic variability with regard to the timing and intensity of waves, although multiple jurisdictions will be affected simultaneously.
- The pandemic is expected to last 12 to 18 months.
- The novel virus is expected to displace other circulating seasonal strains during the pandemic. After the pandemic, the pandemic virus will continue to circulate as a seasonal strain. It may completely replace previously circulating seasonal influenza A subtypes or continue as one of several circulating seasonal A subtypes.
- Relatively more severe disease and mortality is expected to occur in the young and in persons without underlying health conditions compared to seasonal influenza.

3.6.4 Clinical Features

- Population clinical attack rates (averaged across all age groups) are expected to be 25% to 45% over the course of the pandemic.
- Clinical symptoms are expected to develop in about two-thirds of people who are infected with the pandemic influenza virus.
- The general, uncomplicated clinical picture is expected to be the same as for seasonal influenza: respiratory symptoms, fever and abrupt onset of muscle ache, fatigue and headache or backache.
- Persons at high risk for complications from seasonal influenza [31] are expected to also be at increased risk of severe disease and complications from pandemic influenza infection, although additional risk groups may emerge.

3.6.5 Impact and Interventions

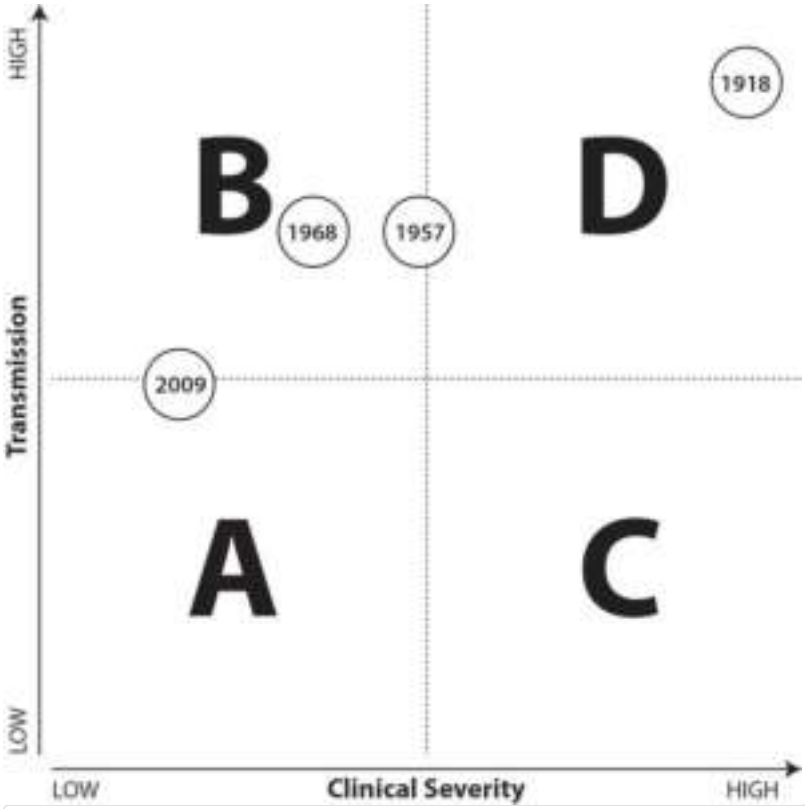
- Impact will vary across communities, and vulnerable populations are expected to be affected more severely.
- Workplace absenteeism may be higher than the estimated clinical attack rate because of caregiving or concern about personal safety in the workplace in addition to worker illness.
- Vaccine is expected to be available in time to have an impact on the overall pandemic but will not be available for the first wave.
- Personal hygiene measures are expected to help to reduce transmission between individuals and within households and other settings.

3.7 Pandemic Planning Scenarios

This section discusses another important tool for pandemic planning. The use of multiple planning scenarios is specifically intended to support the planning principles of evidence-informed decision-making, proportionality, and flexibility; and a precautionary/protective approach.

Planning scenarios provide a starting point to think through the implications and risks that would be associated with pandemics of varying population impact. Scenarios can also be used for exercises and training in support of pandemic plans. To help with risk identification, four pandemic planning scenarios have been developed that describe potential pandemic impacts varying from low to high. Figure 2 displays the four scenarios in a two-by-two table and estimates where the past four pandemics might be placed, according to an analysis conducted by the US Centers for Disease Control and Prevention (CDC). [32]

Figure 2 - Framework for the planning scenarios, with previous pandemics placed as per CDC analysis [33]



▶ Figure 2 - Framework for the planning scenarios, with previous pandemics placed as per CDC analysis - Text Equivalent

Scenario A (low impact) - this scenario involves an influenza virus with low transmissibility (ability to spread) and low virulence (clinical severity). Its impact is comparable to that of moderate to severe seasonal influenza outbreaks or the 2009 pandemic. It might be expected to stress health care services.

Scenario B (moderate impact) - this scenario involves an influenza virus with high transmissibility and low virulence. Its impact is worse than seasonal influenza in terms of numbers ill, which would be expected to stress health care services through sheer volume. High absenteeism would put all sectors and services under pressure.

Scenario C (moderate impact) - this scenario involves an influenza virus with low transmissibility and high virulence. Its impact is worse than seasonal influenza outbreaks in terms of severe clinical illness, which would be expected to stress critical care health services. The high virulence could cause significant public concern and may lead to people staying home from school and work.

Scenario D (high impact) - this scenario involves an influenza virus with high transmissibility and high virulence, and its anticipated impact is much worse than that of seasonal influenza outbreaks. It would cause severe stress on health care services, and high absenteeism would put all sectors and services under extreme pressure.

There are several important points to note about the scenarios:

- Whatever the pandemic impact, the epidemiological picture is expected to be significantly different from that of seasonal influenza, in that relatively more severe disease and mortality will occur in the young and in persons without underlying health conditions compared to seasonal influenza. [34]
- The four basic scenarios do not incorporate all of the potential factors (or “what-ifs”) that can affect the impact of a pandemic and should be considered in risk assessment. Some of these factors are population-wide and could affect all scenarios (such as seasonality, pre-existing immunity or antiviral resistance), whereas others might be setting-specific (such as planning for a remote community). See Appendix A for more details about

these additional factors and their potential impact. Additional risks may also be identified as planners consider all stages of the pandemic and components of the proposed response.

Table 1 provides some added description to the scenarios for planning purposes, along with potential impact considerations associated with each scenario.

Table 1 - Description and potential impact of the four pandemic planning scenarios

	Pandemic scenario			
Nature of impact	**A (low impact)**	**B (moderate impact)**	**C (moderate impact)**	**D (high impact)**
Basic virus characteristics	Low transmissibility/ low virulence	High transmissibility/ low virulence	Low transmissibility/ high virulence/	High transmissibility/ high virulence
Nature and scale of illness	• Similar numbers as in moderate or severe seasonal influenza outbreaks • Mild to moderate clinical features (in most cases)	• Higher number of cases than large seasonal outbreak but similar clinical severity • Overall increased numbers needing medical care and with severe disease	• Similar number of cases as with large seasonal outbreak but illness is more severe • Overall increased numbers needing medical care and with severe disease	• Large numbers of people ill • High proportion with severe disease
Impact on health care services	• Ambulatory and acute-care services stressed but able to cope • ICUs at capacity • Public health and laboratory services stressed • Long-term care may or may not be affected (depending on pre-existing immunity)	• Ambulatory and acute-care services very stressed • Health care services no longer able to continue all activities • ICUs under severe pressure • Long-term care may or may not be affected • Settings with limited surge capacity (e.g., nursing stations) may be even more stressed	• Ambulatory and acute-care services very stressed • Health care services no longer able to continue all activities • ICUs under severe pressure • Long-term care may or may not be affected • Settings with limited surge capacity e.g., nursing stations) may be even more stressed	• Health care services may be overwhelmed • Ambulatory services fully stretched • Hospitals able to provide only emergency services • Triaging necessary for critical care services • Collapse of services could lead to higher mortality than expected • Settings with limited surge capacity (e.g., nursing stations) may be highly stressed

Nature of impact	Pandemic scenario			
	A (low impact)	**B (moderate impact)**	**C (moderate impact)**	**D (high impact)**
Broader societal impact	• Limited workplace disruption • Some school disruption • Elevated public concern	• High workplace absenteeism • Some services experience pressures • Schools likely disrupted • Some supply chain problems • Elevated public concern • Surges in need for health care services.	• Potential workplace absenteeism and school disruption from fear of exposure • Considerable public concern over occurrence of very severe disease	• High absenteeism • Services and businesses under extreme pressure • Potentially severe supply chain problems • Could disrupt provision of basic services • Extreme public concern and psychosocial distress • Mass fatalities may overwhelm death care services (e.g. funeral homes,mortuaries)
Economic impact	Minimal if any	Productivity may be affected	Productivity may be affected	Very high

Initial period when impact is unknown - A formal scenario has not been proposed for the initial period when the pandemic has not yet been characterized in terms of its potential impact. However, some of the possible observations for this preliminary period are as follows:

- sporadic cases and limited outbreaks may be occurring;
- there will likely be elevated demand on telephone information lines, ambulatory care and laboratory services;
- public health services may be stressed;
- elevated media and public concern can be anticipated;
- international travel and trade could be disrupted; and
- there could be increased demand and shortages of publicly available supplies, e.g., infection control and basic emergency supplies, antivirals.

3.8 Pandemic Phases and Triggers for Action

3.8.1 WHO Pandemic Phases

Pandemic phases were introduced into pandemic plans to assist planning and serve as triggers for action, thus supporting the principles of flexibility and proportionate response. Previous Canadian pandemic plans incorporated the WHO pandemic phases, with additional designations proposed to identify activity levels within Canada.

After the 2009 pandemic, the IHR Review Committee [35] recognized that the WHO pandemic phases had presented challenges in interpretation and were used in different ways - as a planning tool, as a method to describe the global situation and/or as an operational tool to trigger action. The Committee recommended simplifying the WHO phase structure and separating operational considerations at country level from the WHO global preparedness plan and its phases.

WHO's 2013 pandemic guidance [36] describes the four phases that WHO will use to communicate a high-level global view of the evolving picture. The phases reflect WHO's risk assessment of the global situation regarding each influenza virus with pandemic potential that is infecting humans. The four global phases are:

- Interpandemic phase - the period between influenza pandemics;
- Alert phase - when influenza caused by a new subtype has been identified in humans. This phase is characterized by extra vigilance and careful risk assessment;
- Pandemic phase - the period of global spread of human influenza caused by a new subtype. Movement between the interpandemic, alert and pandemic phases may occur quickly or gradually;
- Transition phase - reduction of the assessed risk resulting in de-escalation of global actions.

The global phases and their application in risk management are distinct from (1) the determination of a PHEIC under the IHR (2005) and (2) the declaration of a pandemic. These are based upon specific assessments and can be used for communication of the need for collective global action, or by regulatory bodies and/or for legal or contractual agreements, should they be based on a determination of a PHEIC or on a pandemic declaration. [37]

As pandemic viruses emerge, countries face different risks at different times and should therefore rely on their own risk assessments, informed by the global phases, to guide their actions. The uncoupling of national actions from global phases is necessary since the global risk assessment, by definition, will not represent the situation in each country.

3.8.2 Canada's Approach to Pandemic Phases and Triggers for Action

Canada's response to the novel/pandemic virus will relate to its presence and activity levels in this country, which may not coincide with the global picture. Therefore, the WHO global phases will not be used to describe the situation in Canada or be used as triggers for action in Canadian jurisdictions. While the triggers for action described below may parallel some of the global WHO phases, it is not expected that they will line up exactly. For example, Canada might be well into the first pandemic wave before WHO announces the global pandemic phase (as happened in the 2009 pandemic) or conversely Canada might be still anticipating the first domestic outbreaks when the pandemic phase announcement is made.

In the 2009 pandemic, there was considerable variation in pandemic wave activity across Canada and even within PTs, in terms of both timing and intensity. This was particularly apparent in the first wave making blanket descriptions, triggers or responses inappropriate.

Describing pandemic activity

Descriptive terms such as the start, peak and end of a pandemic wave, will be used instead of phase terminology to describe pandemic activity in the country or in a jurisdiction within Canada. Pandemic wave activity can be further characterized for jurisdictions of any size using FluWatch definitions for no activity, sporadic activity, localized activity and widespread activity. [38]

Triggers for action

Triggers for action provide guidance for initiation of FPT activities and for their modification and cessation. Pandemic response should be appropriate to the local situation, so it is important that triggers and related actions be applied at PT or regional/local level as appropriate to the situation. Potential triggers for action in Canadian jurisdictions during the initial alert stages and the pandemic itself are identified in Table 2. The typical actions listed are at a high level; more detailed triggers for individual response components can be found in the annexes. Note that the triggers are not necessarily linear; for example, not all jurisdictions may find their capacity exceeded and therefore some may not need to invoke that particular trigger.

Table 2 - Pandemic Triggers and Typical Accompanying Actions

Trigger	Typical actions for consideration	Comments
Novel virus causing human cases detected somewhere in the world (no or limited transmission)	• Preparations to enhance surveillance within Canada • Intelligence gathering from affected areas • Relevant public and health sector communications	Tailored communications to health sector and general public continue throughout the response
Novel virus with sustained human transmission detected somewhere in the world	• Enhanced surveillance by PTs within Canada • Intelligence gathering from affected areas; preliminary risk assessment • Development of specific laboratory diagnostics • Enhancement of illness prevention messages and other public health measures (e.g., hand hygiene, respiratory etiquette) as appropriate • Confirmation of pandemic vaccine arrangements with manufacturer	Pandemic may be imminent or have already started
Novel/pandemic virus (with sustained human transmission) first detected in Canada	• Continuation of above activities • Activation of health emergency response protocols • Detailed investigations of early cases to determine epidemiological and clinical characteristics and inform risk assessment • Arrangements for antiviral access/strategic deployment of NAS • Provision of clinical guidelines and public health advice	Depending on circumstances, activation of health emergency protocols might already have occurred

Trigger	Typical actions for consideration	Comments
Novel/pandemic virus detected in PT or local jurisdiction	• Treatment of cases • Ramping up health sector capacity to deal with increasing number of cases • Additional public health measures (e.g., school closures) as appropriate • Preparation for vaccine distribution, administration and monitoring • Ongoing surveillance to monitor influenza activity and epidemiological analysis to characterize pandemic • Relevant public and health sector communications • Assess need for supportive emergency and social services (e.g. reception centres, volunteers, faith-based organizations)	Escalation of activities as pandemic activity moves from sporadic cases into full pandemic wave, followed by de-escalation as it wanes
Demands for service start to exceed available capacity	• Further escalation of surge capacity • Prioritization or triage of services as needed • Implementation of broader public health measures (e.g., banning of large gatherings)	May not reach this level in any or all jurisdictions
The pandemic wave wanes and demand for service falls to more normal levels	• Preparation for a resurgence of influenza • Replenishing of supplies as needed in anticipation of another wave • Evaluation of response and revision of plans as required • Preparation for immunization program • Ongoing surveillance to detect resurgence • Assessment of the psychosocial impact on the population (e.g. workforce resiliency, mental health, social cohesion) of the first wave	
Pandemic vaccine is available for administration	• Administration of vaccine as quickly as possible • Monitoring of vaccine uptake, safety and effectiveness	

Trigger	Typical actions for consideration	Comments
Second or subsequent pandemic wave arrives	• Treatment of cases • Continuation of immunization if already started • Ongoing surveillance to monitor influenza activity, antiviral resistance and strain changes	
Pandemic is over and normal activities resume	• Completion of pandemic studies and reports • Evaluation of response and revision of plans as required • Return to more normal operations • Preparation for post-pandemic seasonal influenza	• Identification of lessons learned and their incorporation into pandemic planning are critical activities in the recovery from a pandemic

4.0 Key Components of Pandemic Influenza Preparedness and Response

This chapter provides a high-level overview of the major components of influenza preparedness and response. Each section of the chapter describes the purpose and strategic approach of one of the response components and demonstrates how it supports the overall pandemic goals. Detailed operational guidance and tools for each component can be found in the respective CPIP annex.

All parts of the health sector, including public health, will be under stress during a pandemic. Advance planning, training and exercises will greatly assist in handling this increased demand on health services, staffing, resources and supplies and in providing the best possible clinical outcomes for persons ill with influenza. Continuity of operations and surge capacity planning are key components of health sector preparation, together with strong infection prevention and control and occupational health programs within each organization that provides health services.

Public health authorities play a leadership role in their jurisdiction in pandemic preparedness, response and recovery. They are responsible for communication to the public, the health sector and other stakeholders. The public health response to a pandemic also includes surveillance (both epidemiological and laboratory), the provision of pandemic vaccine and antiviral medications, and the application of public health measures such as promotion of personal and social distancing measures to reduce spread in households and the community.

In planning for the delivery of health services, it is important to encompass the entire continuum of care from medical first response to critical care, and to include community health partners. Planning for the provision of health care needs to be linked with public health and community-wide partners so that interdependencies can be identified and addressed.

The health care system includes workers of many disciplines, who will be at varying levels of risk during an influenza pandemic. HCWs are defined broadly as individuals who provide health care or support services in the health care setting, such as nurses, physicians, dentists, nurse practitioners, paramedics, medical laboratory workers, other health professionals, temporary workers from agencies, unregulated health care providers,

students, volunteers and workers who provide support services (e.g., food, laundry, housekeeping). The concepts and advice that are provided for HCWs also apply to other workers who are functioning in a health care capacity, for example police or fire personnel who are providing medical first response.

4.1 Surveillance

The purpose of pandemic surveillance is to provide decision-makers with the timely information they need for an effective response. Pandemic surveillance uses data obtained through routine and enhanced surveillance activities (e.g., data from sources such as laboratories, PT partners, hospital networks and sentinel practitioners) together with information from special studies to obtain a comprehensive and timely epidemiological picture of the pandemic.

These pandemic surveillance programs will monitor parameters such as:

- the geographic spread of the novel/pandemic virus across Canada;
- the trend of disease occurrence as it rises and falls within each PT and across the country;
- the intensity and impact of the pandemic (e.g., clinical cases, hospitalizations and deaths; severe clinical syndromes and associated risk groups; and demands on the health system); and
- changes in the antigenicity and antiviral sensitivity of the virus.

Strategic approach

A risk management approach to an influenza pandemic requires access to timely information, analysed and presented in a way that is useful to decision-makers. Epidemiological and laboratory surveillance data are key components of the formal risk assessments that will be produced to inform the response. One of the most critical needs is an early assessment of the potential impact of the pandemic so as to prepare the health care system and to plan interventions that are proportional to the situation. Systems or studies to produce the early impact assessment and other required information need to be in place before the pandemic.

Pandemic surveillance should be built on existing surveillance systems for seasonal influenza, which involve an extensive network of surveillance partners and are practised every year.

During a pandemic, collection of additional surveillance elements may be required to identify risk factors for severe disease and populations at increased risk. Targeted surveillance activities may be required for remote and isolated communities, including many Indigenous communities, to describe outbreaks appropriately in these regions. Other special studies (e.g., seroprevalence surveys) will be needed to inform decision-making.

Surveillance activities will need to be adapted in response to rapidly evolving situations; they may be streamlined, expanded or scaled down depending on information needs at particular times within the evolving pandemic. The scope of the pandemic and the urgency of information needs will require expedited and secure electronic data transfer and enhanced capacity for data analysis and interpretation.

More details about pandemic surveillance strategies and activities can be found in the Surveillance Annex.

4.2 Laboratory Services

Laboratory-based surveillance is an integral part of monitoring influenza activity. Because the signs and symptoms of influenza are similar to those caused by other respiratory pathogens, laboratory testing must be conducted to diagnose influenza definitively. Rapid identification of a novel influenza virus and timely tracking of virus activity throughout the duration of the pandemic are critical to the success of a pandemic response. In the early stages of a pandemic, laboratory services also contribute to appropriate clinical treatment.

The purpose of laboratory services during a pandemic is to:

- identify the first cases of a novel influenza strain occurring in Canada;
- support public health surveillance by monitoring the geographic spread of disease and the impact of interventions;
- facilitate clinical management by distinguishing patients infected with the pandemic influenza virus from those with other respiratory diseases;
- monitor circulating influenza viruses for antiviral resistance and strain characteristics; and
- assess influenza vaccine match and support vaccine effectiveness studies.

Strategic approach

The pandemic laboratory response is built on the principles of collaboration, flexibility and use of established practices and systems. As part of annual influenza surveillance, all public health laboratories and other laboratories that routinely test for influenza submit aggregate data weekly during the influenza season to the National Microbiology Laboratory (NML). These data are collated and disseminated by PHAC through the Respiratory Virus Detection Surveillance System and FluWatch. In addition, public health laboratories and other designated laboratories across the country submit isolates to the NML to monitor for antigenic changes within the circulating viruses. This information is shared with international partners through GISRS. Sustaining these relationships and strengthening capacity within the laboratory system during the interpandemic period will support a timely and effective pandemic response.

During a pandemic, influenza testing laboratories will support epidemiological efforts to track the spread and trends of the pandemic, monitor antiviral resistance and support clinical management. The Canadian Public Health Laboratory Network (CPHLN) will support public health and diagnostic laboratories by providing recommendations and best practices for specimen collection and testing for the novel influenza virus. The NML will share protocols, reagents and proficiency panels to ensure that test methods are capable of detecting the new virus. Molecular testing is the primary method used for the diagnosis of influenza.

Antiviral resistance will be monitored and outcomes will inform clinical management of patients. Antiviral resistance testing is conducted primarily at the NML, as well as some provincial laboratories.

The laboratory response will be adjusted as the pandemic progresses. Initially the NML will be heavily engaged in characterization of the novel virus and development of diagnostic reagents. All laboratories should anticipate high test volumes initially as the novel virus spreads across the country. During peak periods, laboratories will need to prioritize specimen collection to prevent overload. At this point, diagnosis of influenza in the community will be made primarily by clinical assessment; however, testing to support the management of certain patients (e.g., those requiring admission to hospital) will be expected to continue together with identification of outbreaks and surveillance. If ongoing monitoring shows increasing levels of antiviral resistance, more testing may be necessary to support clinical management of severely ill patients, especially those not responding to treatment.

Throughout the pandemic, public health, diagnostic and research laboratories, including those involved in the Canadian Immunization Research Network (CIRN), will also play an important role in supporting studies to better understand the novel pandemic virus and its impact.

More details about pandemic laboratory strategies and activities can be found in the Laboratory Annex.

4.3 Public Health Measures

Public health measures are non-pharmaceutical interventions that can be taken by individuals and communities to help prevent, control or mitigate pandemic influenza. Public health measures range from actions taken by individuals (e.g., hand hygiene, self-isolation) to actions taken in community settings and workplaces (e.g., increased cleaning of common surfaces) to those that require extensive community preparation (e.g., pro-active school closures). The purpose of public health measures is to:

- reduce transmission of the novel/pandemic virus, thereby helping to reduce the overall size of the outbreak and the number of severely ill cases and deaths; and
- slow the rate of transmission in order to reduce the peak burden on the health care system and buy time in anticipation of vaccine.

Strategic approach

Public health measures are typically implemented at the community level. The responsibility and legislative authority for implementing public health measures belong to the relevant PT and local public health authorities, with the exception of international border and travel related issues for which the federal government is responsible. In addition, the Canadian Forces Health Services is responsible for implementing public health measures on all Canadian Forces establishments/bases/wings/stations across Canada and for Canadian Forces personnel deployed abroad.

There are important concepts to consider when planning and implementing public health measures. The measures should be used in combination to provide “multi-layered protection”, as the effectiveness of each measure on its own may be limited. Actions should be tailored to the anticipated pandemic impact and the local situation, supporting the principles of flexibility and proportionality. Some measures, like hand hygiene and respiratory etiquette, are applicable in all pandemics. Other measures (e.g., proactive school closures and travel restrictions) might be used only in moderate- to high-impact situations, as they can be associated with significant societal and economic costs.

A risk management approach will help weigh the potential advantages of particular interventions against their disadvantages and unintended consequences. Decisions about which measures to deploy also raise fundamental ethical challenges. For example, when considering restrictive measures, it is important to balance respect for autonomy against protection of overall population health. In such situations, the principles of proportionality, reciprocity and flexibility are involved, with a view to safeguarding individual freedom to the extent possible while promoting protection against the health and societal consequences of influenza infection.

There are several types of public health measures for jurisdictions to consider during an influenza pandemic:

- **Individual measures** - Public health advice will be provided to protect well individuals against influenza and prevent ill individuals from spreading infection, e.g., through hand hygiene, cough etiquette, staying home while sick. These measures should already be familiar through annual public health campaigns.
- **Community-based measures** - Guidance will be produced and disseminated to minimize illness and transmission of infection within settings such as workplaces, schools, post-secondary institutions, childcare centres, communal living facilities, remote and isolated communities, camps and cruise ships. Social distancing measures or strategies may be used to minimize close contact among persons in public places, e.g., pro-active school closures; cancellation or modification of public gatherings; and alternative workplace approaches, such as teleconferences and working from home. Because of their potential societal impact, social distancing measures are most applicable in pandemics of moderate to high impact.
- **Border and travel measures** - These interventions include provision of travel health advice, screening of travellers and travel restrictions. Evidence for their effectiveness is limited and their implementation would

depend on the risk assessment and resultant risk/benefit analysis of the actions being considered.

- **Case and contact measures** - Some circumstances involving novel/pandemic viruses may warrant case and contact management by public health authorities. These might include an individual human case or cluster involving a novel virus, suspected human infections associated with an animal influenza outbreak, or initial cases of the pandemic virus in the country or area. The extent of the investigation and recommended measures should be feasible and relevant to the situation.

While aggressive measures (e.g., widespread antiviral use and restriction of movement) to attempt to contain or slow an emerging pandemic in its earliest stages were previously considered possible on the basis of modeling, experience from the 2009 pandemic has resulted in general agreement that such attempts are impractical, if not impossible.

Additional details about public health measures can be found in the Public Health Measures Annex.

4.4 Vaccine

Immunization of susceptible individuals is the most effective way to prevent disease and death from influenza. The purpose of Canada's pandemic vaccine strategy is to:

- provide a safe and effective vaccine for all Canadians as quickly as possible;
- allocate, distribute and administer vaccine as efficiently as possible; and
- monitor the safety and effectiveness of pandemic vaccine.

The phrase "vaccine for all Canadians" is intended to be interpreted broadly. It refers to all persons in Canada (whether or not they are citizens) as well as Canada-Based Staff (CBS), their dependents and Locally Engaged Staff (LES) at Canadian missions abroad and Canadian active duty personnel (Canadian Forces) abroad.

An effective pandemic vaccine strategy is built on strong seasonal influenza immunization programs. The overall impact of the pandemic vaccine strategy will depend on vaccine efficacy and uptake, as well as the timing of vaccine availability in relation to pandemic activity. Using current egg-based vaccine production technology, pandemic vaccine production is expected to take from four to six months, so it is not likely to be available by the time the first pandemic wave reaches Canada. Furthermore, it will become available in stages, which may require prioritization of initial vaccine doses.

Strategic approach

In 2011, Canada entered into a new ten-year contract for pandemic influenza vaccine supply to ensure that there is rapid and priority access to a supply of adjuvanted pandemic influenza vaccine produced in Canada. Canada's pandemic vaccine strategy also includes contracting for a secondary supply of a pandemic vaccine.

Health Canada has developed a regulatory strategy to review and authorize a safe and efficacious pandemic vaccine for use in Canada within the shortest time frame possible. A pan-Canadian approach to pandemic immunization, including prioritization of populations during initial roll-out of the vaccine, will help optimize equitable access and desirable outcomes. Pan-Canadian guidance will include an allocation plan for equitable vaccine distribution, recommendations for pandemic vaccine use and recommendations for prioritization of initial supplies.

Other key elements of the national vaccine strategy include the monitoring of vaccine uptake, adverse events and vaccine effectiveness, building on existing systems such as the Canadian Adverse Events Following Immunization Surveillance System (CAEFISS). Rapid studies will be carried out to confirm or refute vaccine safety concerns.

PTs, Canadian Forces Health Services, and federal departments with the responsibility for immunization should have plans for efficient and timely vaccine administration, including the ability to target key population groups and collect information on vaccine uptake and adverse events. Lessons learned from the 2009 pandemic indicate that vaccine registries and electronic information systems to capture and transmit data are essential tools to support the vaccine program.

More details about the pandemic vaccine program can be found in the Vaccine Annex, including a prioritization framework to guide decision-making if vaccine is expected to be in short supply.

4.5 Antiviral Medications

Antiviral medications can be used to treat influenza cases or to prevent influenza in exposed persons (prophylaxis). Antiviral medications are the only specific anti-influenza intervention available that can be used from the start of the pandemic, when vaccine is not yet available.

Canada's antiviral strategy supports FPT stockpiles of antiviral medications for use in the event of an influenza pandemic, primarily for early treatment and for outbreak control in closed facilities. Early treatment of influenza cases, as early as possible within 48 hours of symptom onset, is recommended in order to reduce the severity and duration of illness, particularly the occurrence of influenza-related complications, hospitalization and death. Early treatment may also help mitigate societal disruption by reducing the duration and severity of illness experienced by workers in the health care and other critical infrastructure sectors.

Strategic approach

There are two national stockpiles in Canada:

- The NAS is a stockpile that is held and managed by the PTs. The NAS is composed of the antiviral medications oseltamivir and zanamivir, with oseltamivir dosage formulations that are appropriate for both adults and children.
- The NESS is a federally owned stockpile of emergency supplies. The NESS is held and managed by PHAC and includes a stockpile of oseltamivir and zanamivir. NESS antivirals are intended to provide surge capacity in support of the PT response during a pandemic.

Federal government departments, such as the Canadian Forces (for active duty personnel) and Global Affairs Canada (for mission staff overseas), hold stockpiles of antiviral medications to meet the anticipated needs of their staff.

Jurisdictions need strategies to facilitate timely access to antiviral medications, particularly for high-risk persons including pregnant women, children (who need special formulations), vulnerable populations, and residents of remote and isolated communities. Pre-positioning of antiviral medications should be considered for some communities to facilitate rapid access (e.g., remote northern communities).

Clinical guidelines have been developed for antiviral use for seasonal influenza. [39] Virus-specific clinical guidance and treatment protocols will need to be developed at the onset of the pandemic, based on pandemic epidemiology and available scientific evidence. Pandemic use will focus primarily on early treatment of influenza cases, particularly persons with severe disease or with risk factors for complications or severe disease. There are limited indications for the use of antiviral medications for prophylaxis during a pandemic, primarily for control of laboratory-confirmed influenza outbreaks in closed health care facilities and other closed facilities or settings where persons at high-risk of complications reside.

Distribution and uptake of antiviral medications should be monitored in real time to optimize appropriate use, identify the need for additional purchases during the pandemic, and support post-pandemic utilization and effectiveness studies. Monitoring adverse reactions and antiviral resistance helps inform decision-makers as to whether changes in the recommendations regarding antiviral use are required. Adverse reaction reports are collected and assessed through the Canada Vigilance Program of the Marketed Health Products Directorate (MHPD) of Health Canada. Ongoing monitoring of antiviral resistance is conducted by the public health laboratory system and reported as part of FluWatch.

More details about antiviral medications and their use in a pandemic can be found in the Antiviral Annex, including a prioritization framework to guide decision-making if antiviral medications are expected to be in short supply.

4.6 Infection Prevention and Control and Occupational Health

A major influenza outbreak may have a substantial impact on the ability of health care organizations to keep those providing or receiving health care services safe. Infection prevention and control (IPC) and occupational health (OH) programs should work together to prevent exposure to and transmission of pandemic influenza during the provision of health care. Working jointly with occupational health and safety committees is essential in meeting these goals. The application of appropriate IPC and OH processes by HCWs and organizations is important in all health care settings along the continuum of care, including but not limited to medical first response, practitioners' offices and other ambulatory care settings, acute care, long-term care and home care settings.

Strategic approach

A timely pandemic response is only possible when an organization and its personnel are experienced in IPC and OH protocols and practices, supported by strong programs. Well-functioning IPC programs should prevent, limit or control the acquisition of health care associated infections for everyone in the health care setting, including patients, HCWs, visitors and contractors. Well-functioning OH programs should identify workplace hazards and support appropriate processes and training to ensure that employees can perform their duties in an environment that minimizes exposure to environmental hazards.

Important elements of IPC and OH programs for pandemic preparedness and response in the health care setting include the following:

- adequate staffing of IPC and OH professionals in the health care organization to conduct education and training for front line staff;
- organizational risk assessments, best carried out in the interpandemic period, to identify engineering, administrative and personal protective equipment (PPE) controls that will best protect patients, HCWs and visitors in the health care setting;
- comprehensive education and training for HCWs in the organization on influenza IPC and OH issues;
- point-of-care risk assessments that are carried out by individual HCWs before they enter a patient's environment or initiate patient care to determine the appropriate PPE, isolation and cohorting strategies for a given patient, during a given intervention, in a specific room, area or facility;
- provision of influenza vaccine to persons working for or being cared for by the organization;
- ongoing surveillance for health care associated infections, including respiratory infections;
- respiratory protection programs to ensure that HCWs who may need to wear a respirator (including N95 respirators) are trained, fit-tested and prepared;
- a wide range of "source control" policies, including a 2-metre spatial separation between infected sources (e.g., patients) and uninfected hosts (e.g., other patients); admission screening; screening of visitors; and

expanded respiratory and hand hygiene programs for HCWs, patients and visitors; and
- systematic administrative practices to enable rapid identification and segregation of patients, HCWs and visitors with symptoms of influenza-like illness (ILI).

For detailed guidance about IPC and OH activities during a pandemic, see the annex on Prevention and Control of Influenza during a Pandemic for all Healthcare Settings.

4.7 Health Care Services

The effective provision of health care provides patients with the right level of care in the right place, at the right time. In a pandemic this means managing an influx of patients with influenza, while maintaining care required for patients with urgent non-influenza conditions. It is necessary for any organization that provides health care to plan for a range of scenarios, including those with very high patient load and potential high staff absenteeism, as demand for health care services may exceed the capacity of the existing system. At the start of a pandemic, early assessment of its anticipated impact will help the health care sector to implement plans to manage the anticipated workload.

Strategic approach

Planning for the delivery of health care in a pandemic is a particular challenge as there is little excess capacity in the Canadian health care system, particularly in remote and isolated communities. Nonetheless surge capacity planning is an essential component of pandemic preparedness for all levels of care, including telephone information lines, primary and ambulatory care practitioners, emergency medical services, hospital and critical care, long-term and palliative care, home care and other community care including death care services (funeral homes, medical examiners, coroners). Surge capacity planning involves development of strategies for enhancing levels of staff and volunteers, equipment and supplies and, potentially, space to accommodate more patients. It also includes consideration of novel approaches to enhancing assessment and care. Surge capacity plans should include regional or even province-wide components.

The 2009 pandemic highlighted the importance of improving integration and coordination so that the health care response functions as a system during an emergency. This involves integration across the continuum of care within a health region and across and among PTs. Integration is facilitated by involving stakeholders from all levels of care in planning and exercises, including emergency medical services, community service providers, volunteer organizations and public health. Electronic information management systems are essential tools for monitoring service delivery and resource utilization across the health care system and transferring information among organizations.

The collection of health care delivery data is an important aspect of seasonal and pandemic influenza surveillance. Monitoring hospital and ICU admissions and ventilator use were added surveillance components in the 2009 pandemic, contributing valuable information on the epidemiology of severe disease and its risk factors. Surveillance of emergency department utilization can indicate when community health services are at or reaching capacity so that other measures can be considered.

Best practices and lessons learned advise that health care organizations and practitioners carry out business continuity planning and maintain strategic reserves of critical equipment and supplies. Detailed plans to store, distribute and track use of stockpiled items should be developed and exercised.

Pandemic-specific issues for health care provision include the following:

- **Self-care instructions** - self-care instructions can empower individuals and families, improve care and optimize the use of the health system; they are useful for dealing with seasonal as well as pandemic influenza. During the 2009 pandemic, many jurisdictions used the media, public announcements and credible websites to promote tools to assist the public on conducting an influenza self-assessment, self-care and when to seek medical attention or go to the hospital.
- **Telephone advice lines** - these were extensively used in the 2009 pandemic to provide information and advice, and to triage people with suspected influenza from those with other respiratory infections. Trained operators directed people to appropriate clinical assessment and care if needed, and helped avoid unnecessary visits to physicians and emergency departments by providing advice on self-care at home. Heavy, and sometimes overwhelming, demand reinforced the necessity for business continuity planning and for operation on a 24/7 basis during a pandemic.
- **Primary care** - the primary care sector will be responsible for the assessment and treatment of ambulatory influenza patients. PTs often face challenges in engaging primary care practitioners, who may not be well linked to the rest of the system. PTs should work with professional associations to develop communications strategies, protocols and guidelines, e.g., for office business continuity planning and IPC. At the time of the pandemic, PTs should anticipate providing primary care practitioners with situation updates, guidance on laboratory testing and clinical management of influenza patients, information on pandemic vaccine (with clear direction on their role in its provision) and access to additional or pre-positioned PPE and supplies. Primary care surge capacity can be enhanced by PT strategies such as new fee codes for telephone advice and prescribing, temporarily allowing practice expansion to patients who are not registered with the practice (when this is not normally permitted), and expanding the role of other health professionals and non-traditional workers (e.g., allowing prescribing of antiviral medications by pharmacists). Influenza assessment centres and alternate care sites may be needed in some communities, particularly in high-impact situations. Responsibility for their establishment is best determined in advance so that appropriate planning can take place.
- **Hospital-based care -** the impact on the acute care sector and the demand for critical care will be influenced by the epidemiology of the pandemic, i.e., the overall numbers with severe disease, the age and risk groups most at risk of severe disease and the dynamics of the pandemic wave (compacted or prolonged), as well as the extent of early antiviral treatment in the community. Critical care planning and preparation for high demand for ventilators or other specialized equipment (e.g., extracorporeal membrane oxygenation) needs special attention. Critical care surge capacity plans should include triage tools that contain both ethical guidance and processes to address bed flow and ventilator utilization. Service needs for paediatric patients (including critical care) and pregnant women should be specifically addressed.
- **Health care in remote and isolated communities** - There may be limited capacity to provide acute care and/or a lack of appropriate medical equipment and services (e.g., ventilators, oxygen therapy) for treating critically ill patients in remote and isolated communities. Under normal circumstances, these needs are met through medical evacuations to acute care facilities in larger centres. However, an increase in medical evacuations could overwhelm the receiving jurisdictions, making it essential to coordinate with receiving jurisdictions and to do everything possible to detect ILI as early as possible and to treat and keep affected persons in the community.
- **Other health care services** - services such as mental health, home care, palliative and hospice care, long-term care and other community health and social services may not be well linked to regional and local pandemic planning processes. Though often overlooked in pandemic planning, their functioning is critical to achieving the pandemic objectives by providing early and appropriate treatment outside of hospitals to those who do

not need acute hospital care. These organizations must be involved in pandemic planning and encouraged to have business continuity plans in place so that they can continue to provide their services to some of the most vulnerable patients in the community with minimal interruption during a pandemic.

During a severe pandemic, death care services may be overwhelmed and local planners may need to consider alternate systems and resources than those that normally manage deaths, such as setting up temporary morgues and delaying funerals/burials. This may cause increased stress or complications in the grieving process for families, particularly when certain religious and/or cultural practices have specific directives about how bodies are managed after death. Planning guidance is available from the WHO, Pan American Health Organization and the International Red Cross on the effective management of mass fatalities during a disaster [40].

4.8 Clinical Care Guidelines

Clinical care involves the assessment and treatment of persons with suspected or confirmed pandemic influenza. The spectrum of illness seen with influenza is broad and ranges from asymptomatic infection to severe illness causing death, which is frequently due to exacerbation of an underlying chronic condition or secondary bacterial pneumonia. Certain aspects of pandemic influenza management may be unfamiliar to some practitioners, and new risk factors and presentations may emerge. Critically ill patients may require extraordinary support measures, some of which may not be universally available in a high-impact pandemic.

Strategic approach

During a pandemic, health care practitioners will need clinical guidelines for assessment, laboratory testing, treatment (including antiviral medications), and management of secondary infections and critically ill patients. Service needs for specific populations (e.g., paediatrics, pregnant women) should be specifically addressed. Guidelines specific to the clinical management of patients in remote and isolated communities should also be available, as there are unique considerations in these settings.

Clinical care guidelines must be timely and user-friendly, and be produced by sources that practitioners consider reliable. Establishing and testing agreed upon approaches for the development of clinical guidelines during the interpandemic period will help to ensure that the necessary processes are in place to support the pandemic response.

4.9 Communications

Communication of information and advice is often the first and most important public health intervention during an emergency. This is especially true for an emerging pandemic, where behaviour change is a central part of risk management. Providing clear and consistent information about the disease, who it affects, how it spreads and ways to reduce risk is an effective way to help reduce the spread of infection before other interventions like vaccine are available. Open and honest public communication also reinforces trust in public health authorities and helps to minimize societal and economic disruption.

Communications planning for an influenza pandemic uses a risk communications approach. [41] It integrates a broad range of communication capacity and expertise, including social marketing, stakeholder consultation and use of social media. It involves collaboration of all partners involved in the pandemic response to deliver consistent, complementary, and effective communications that meet the needs of the public and stakeholders.

For details on the pandemic risk communication approach, see the Communications and Stakeholder Liaison Annex.

Strategic Approach

Pandemic risk communications incorporate the principles of collaboration, proportionality, flexibility and use of established practices and systems. Research conducted during and after the 2009 pandemic reinforced the importance of core risk communication principles such as transparency and stakeholder collaboration in achieving pandemic response objectives. [42]

It is essential to be proactive about communication throughout the pandemic, with information and updates for the media, the public, and other stakeholders. Information may be limited initially and will change as the science evolves and more is learned. The post-2009 pandemic reviews identified difficulties in communicating uncertainty and dealing with changing information, particularly for pandemic vaccine. Therefore, strategies to communicate risk, uncertainty and changing information are critical.

Communicating in ways that demonstrate transparency, cultural sensitivity and use of plain language is essential in building and maintaining public trust. Consistent messaging and “speaking with one voice” will also foster trust and understanding and help avoid confusion.

While communication and messaging within jurisdictions is ultimately a PT responsibility, pandemic communications planning should involve all health partners. The FPT communication response will be coordinated through the PHN Communications Network. Collaboration with nongovernmental, private sector and international organizations is also important. The media should be seen as a key partner and engaged in the interpandemic period as well as during the pandemic.

Communication with the public - Research has demonstrated that risk perception is the strongest indicator of willingness to change behaviour during a public health event, and that it is largely shaped by the public’s emotional response to the event. [43] Monitoring of public perception, information needs and concerns is an important role in the pandemic response and should be planned for. Effective stakeholder identification and engagement will also play a large part in this work. Building relationships with stakeholders in the interpandemic period will help facilitate productive interactions during the pandemic. Federal and PT pandemic communications plans should pay particular attention to reaching vulnerable populations and persons who may have limited access to mainstream media. These groups may require a tailored communications approach, using a variety of formats and delivery mechanisms (e.g., using ethnic media outlets as a conduit to ethno-cultural communities). [44]

Communication with the health care sector - Communications with HCWs and organizations deserves special attention in the planning process. These stakeholders should be engaged in two-way dialogue to help ensure that products and messages meet their needs for timely, clear, concise and relevant communications. Resources should be developed in the interpandemic period so they can be quickly adapted when a pandemic occurs.

For details on the pandemic risk communication approach, see the Communications and Stakeholder Liaison Annex.

4.10 Research

Research plays a key role in addressing knowledge gaps about the influenza virus and effective influenza prevention, treatment and control for both seasonal and pandemic influenza. Much of this research can be carried out in the interpandemic period, but some can only be conducted during a pandemic. Given the potentially long interval between pandemics, it is important not to miss these infrequent but invaluable opportunities and to plan for a rapid research response.

Strategic Approach

Key components of a successful pandemic influenza research strategy include identification of research needs, development and ongoing support of partnerships and research networks, identification of sustained funding sources, and advance establishment of protocols and rapid ethics review processes for pandemic research. Knowledge translation strategies to bring significant findings to decision-makers in a useful and timely way are other key components.

Identification of research needs - It is important that influenza research needs are periodically reviewed and prioritized. This information is helpful to funding agencies like the Canadian Institutes of Health Research (CIHR) and PHAC, and feeds into similar international initiatives by WHO and others. The annexes to this document identify existing research needs in specific areas of the response, such as vaccines and antiviral medications.

Research network - Networks that are created to conduct research in the interpandemic period are well placed to facilitate pandemic research. Provincial public health agencies and PHAC are increasingly collaborating on epidemiological and other public health studies. The Canadian Immunization Research Network (CIRN), a national network of key vaccine researchers is active in ongoing influenza vaccine research projects. The mathematical modeling community has developed several networks and is collaborating more closely with public health. Canadian intensive care researchers have developed international clinical networks, such as the International Forum for Acute Care Trialists (InFACT), that will establish open access protocols, data-sharing processes and ethical frameworks to streamline the response to a new emerging disease or pandemic. These existing networks need ongoing support. As they may not be sufficient to address all of the pandemic research needs, ongoing focus on this aspect is required to ensure readiness for the research response. eds, ongoing focus on this aspect is required to ensure readiness for the research response.

Rapid research response - Special research studies, such as seroprevalence studies and the role of bacterial pathogens in serious outcomes, will be needed to inform pandemic decision-making. As these studies must be mounted quickly, advance planning is critical for their success and timeliness. Leveraging existing partnerships among PHAC, Health Canada, provincial public health agencies, clinical and academic institutions and networks together with populations of research interest such as CIRN and CIHR and engaging them in planning for a rapid research response is essential. Advance plans should include preliminary agreements with potential researchers and development of research protocols and strategies for rapid ethics approval and funding arrangements.

Knowledge translation - Many important decisions must be made quickly during a pandemic. Evidence-informed decision-making requires strong knowledge translation strategies to ensure that existing and new research findings are taken into account. Enabling strategies include compiling research findings from the 2009 pandemic and maintaining up-to-date literature reviews in key areas, such as the effectiveness of public health measures, relevant vaccine studies, and antiviral treatment and resistance. Processes for critical appraisal and dissemination of new research findings should be established in the interpandemic period. Strategies should also be developed to help decision-makers understand and make optimal use of evidence and research.

5.0 Assessment and Evaluation of Pandemic Preparedness and Response

Preparing for and responding to a pandemic is a complex process that requires the coordinated efforts of all orders of government in collaboration with their stakeholders. To ensure that pandemic plans (or all-hazards plans according to the jurisdiction) are comprehensive and effective, jurisdictions should assess their level of preparedness, test their plans regularly and evaluate their pandemic response.

5.1 Assessing Preparedness

Preparedness is a responsibility of individuals, organizations and jurisdictions at all levels. PTs are responsible for preparedness activities that will take place at the PT level and they may also provide advice and/or support to regional and local areas. Assessing the level of pandemic preparedness enables jurisdictions to monitor the progress of their pandemic planning, identify gaps and prioritize future planning efforts. Use of checklists, perhaps coupled with site visits, are potential tools for monitoring progress and levels of preparedness.

It is also important to determine whether responses can be implemented effectively so as to achieve the intended results. Training and exercises should be conducted on a regular basis to maintain preparedness levels as part of a cycle of continuous improvement. Training should also be made a priority for new workers. Exercises can take many forms, ranging from discussion-based activities such as seminars and workshops to larger more complex activities such as activating plans and simulating response activities. It is best for organizations to work their way up to larger exercises. This progression allows organizations to understand their plans better and identify interdependencies, and to make changes and adjustments before attempting a larger, more complicated activity. Following an exercise a formal After Action Report should be prepared, along with an implementation plan to address the gaps identified. Problem areas or weaknesses should be corrected through additional training and/or changes or additions to plans.

In addition to specially designed exercises, seasonal influenza provides annual opportunities for all jurisdictions to test specific components of a plan. For example, seasonal influenza immunization campaigns allow PTs to test rapid distribution of vaccine and supplies while local jurisdictions can practise mass clinic strategies and use of their health emergency management mechanisms to organize the clinic rollout. Other emergencies also provide opportunities to practise and refine components of an effective pandemic response, like command and control and communications.

5.2 Evaluating the Pandemic Response

For future reference, it is important to document completely the processes and activities used and decisions made during the response to the pandemic, along with the outcomes achieved. The response should be evaluated to see if it was carried out as intended and that it led to the desired outcomes. This evaluation helps ensure that lessons learned from the real life event are captured and remain available to inform pandemic plan revisions. The evaluation involves assessment through an After Incident or Lessons Learned report following the pandemic, accompanied by an implementation plan to address the identified gaps. A critical opportunity to evaluate and adjust the response also comes at the end of the first pandemic wave.

In addition to gleaning lessons learned from the pandemic response, it is important to ascertain how well the pandemic response met the goals and objectives of pandemic preparedness and response in Canada. Lessons learned would focus on the assessment of the strategic approach for the key components outlined in this document as a measurement of how well the response met the identified purposes of each of the key components. This higher level and formal evaluation of the pandemic response would involve FPT partners and consider various aspects of the pandemic response. A comprehensive, harmonized approach to pandemic evaluation across jurisdictions should be developed in the interpandemic period so that the main findings and best practices can be identified.

Appendices

Appendix A - Factors Affecting Pandemic Impact

The table lists a series of factors that could affect the impact of a pandemic and describes their potential impact. Consideration of these factors and their potential mitigation will supplement use of the basic planning scenarios and help planners prepare a more adaptable response.

Table - Factors that affect pandemic impact and their potential impact

Category	Factor	Potential impact
Virus characteristics		
Transmissibility	Degree of transmission	High infectivity means that a large number of people will become ill. This would affect absenteeism in schools and workplaces, including health care settings. Health care services would face increased demand. Disruptions in basic services could occur if absenteeism affects critical infrastructure.
	Speed of spread	A concentrated wave with many people ill over a short period would have higher impact on absenteeism and demand for health care than the same number of cases spread over a longer period.
	Season of arrival	Transmission is lower in spring and summer so pandemic waves in that period might be smaller. Higher impact would also be expected with late fall/winter waves due to juxtaposition of usual winter pressures from other viruses and co-circulating bacteria.
Virulence	Clinical severity	High virulence means a high proportion of severe cases among the ill, placing strain on acute and critical care services. The typical pandemic mortality age shift to younger age groups could also increase public concern. Unexpected clinical features could affect provision of acute and critical care.
Population vulnerability		
Population vulnerability	Pre-existing population immunity	Pre-existing population immunity might be present in persons above a certain age due to previous circulation of related strains. This could reduce their risk of infection (although their age might increase their risk of severe disease if they did become ill). Sparing of older persons would significantly reduce overall impact on hospitals and long term care facilities. Higher impact would be anticipated if all age groups are involved.
	Unexpected risk factors	New risk factors for severe disease could mean that more people need health care services. They could also affect vaccine prioritization.
	Special groups and settings	Impact may be increased in high-risk populations or settings (e.g. remote communities, homeless shelters and overcrowded housing). Risk could be elevated because of age, underlying health conditions, poor access to health care, poor socioeconomic conditions, etc.
Response factors		
Public health interventions	Vaccine availability, timing, effectiveness	Timing of vaccine availability in relation to pandemic activity could influence vaccine prioritization and affect uptake. Vaccine impact would be reduced if most people experience illness before vaccine is available.
	Antiviral availability and resistance	Antiviral supply might be insufficient in a very large pandemic. Antiviral drug resistance would reduce supply of effective antiviral medications, thus resulting in need to prioritize use. Supply issues could lead to increased numbers of hospitalizations, severe illness and death.

Category	Factor	Potential impact
	Public health measures	In some circumstances (e.g. virus with lower transmissibility), wide adoption of public health measures could lead to significant reduction in transmission.
Health care system response	Access to care	Good access to primary care and early antiviral treatment would reduce rates of complications and hospitalizations. Lack of access to critical care could increase mortality in seriously ill patients.
	Surge capacity	Lack of surge capacity could affect outcomes if demand for services outstrips supply. Triaging of critical care services would be needed as surge capacity is exceeded. As services become overwhelmed, mortality might increase in both influenza and non-influenza emergency patients.
	Availability of antibiotics and other drugs, supplies	Drug supply problems or antibiotic resistance could affect clinical outcomes. Shortages of infection control supplies could affect viral transmission and increase staff concern.
Risk communications	Behavioural response	Levels of public awareness and understanding and risk perception, along with level of trust in health authorities, could affect degree of adoption (and therefore potential effectiveness) of preventive behaviours such as infection prevention behaviours, social distancing, and uptake of vaccine and antiviral medications.

Appendix B - Pandemic Risk Assessments

The table identifies relevant considerations for initial and ongoing pandemic risk assessments and identifies potential sources of data to generate the information needed. In a pandemic, the Public Health Agency of Canada will prepare or arrange for the risk assessments to be prepared and disseminated.

Table - Pandemic Risk Assessments

Category	What information is needed?		How will this be learned?
	Initial risk assessment	**Ongoing risk assessments**	
Overall response			
Nature of response	• What will be the overall impact?	• Is the impact changing? • How are we coping?	• Estimates/predictions of impact (see sections below)
Characteristics of the virus			
Transmissibility	• How fast will it spread?	• Will there be more than one pandemic wave? • Is transmissibility changing?	• Molecular and genetic studies • Incubation period and generation time • Reproductive number (R0) • Real-time modeling

Category	What information is needed?		How will this be learned?
	Initial risk assessment	**Ongoing risk assessments**	
	• How many will be affected? • See also population vulnerability	• Will follow-up waves be larger or smaller? • When will the next wave begin, peak, end?	• As above • Serological attack rate • Clinical attack rates in various settings
Virulence (clinical severity)	• How severe is the disease? • What proportion of ill people will have complications, need hospitalization, die? • Are there unusual clinical presentations?	• Is disease severity changing?	• Molecular and genetic studies • Rates of hospitalization, intensive care unit (ICU) admission, ventilator use • Case fatality rate/ratio • Clinical case series of persons with severe disease • Outbreak reports
Population vulnerability			
Population vulnerability	• Will all age groups be affected and to what extent?	• How is population immunity changing as the outbreak progresses?	• Levels of pre-existing population immunity • Periodic seroprevalence surveys
	• What are the risk factors for severe disease?	• Are new risk factors/groups emerging?	• Epidemiological studies • Clinical case series • Outbreak reports
	• Are there settings and populations at increased risk?	• Are there additional settings and populations at increased risk? • Are we effectively targeting our interventions? • Any unintended consequences from our interventions?	• Epidemiological studies • PT/NGO feedback • Socioeconomic data
Public health interventions			

Category	What information is needed?		How will this be learned?
	Initial risk assessment	**Ongoing risk assessments**	
Antiviral medications	• Is there antiviral resistance? • Will antivirals be safe? • Will antivirals be effective? • Are we able to effectively mobilize the NAS?	• Are antiviral resistance patterns changing? • Are the antivirals safe? • Are the antivirals effective? • Are the right patients receiving them in a timely way?	• Antiviral susceptibility and resistance testing • Antiviral distribution and uptake • Adverse reaction reports • Effectiveness studies • Distribution reports and special studies
Vaccine	• Will vaccine be safe? • Will vaccine be effective? • When will it be available?	• When will vaccine be available? • Are there changes to the usual high-risk groups? • Is there adequate capacity for rapid immunization? • How can vulnerable groups be reached? • Is pandemic vaccine safe? • Is it effective?	• Early epidemiological studies (re: high-risk groups) • PT monitoring and feedback • Vaccine uptake and effectiveness • AEFI reports
Public health measures	• What is the anticipated impact, including on transmission?	• Are the interventions acceptable? • Are they effective?	• Measures of transmissibility and virulence • Mathematical modeling • Public opinion research • Community surveys
Infection prevention and control (IPC)	• Will the usual IPC measures be effective? • If not or unsure, what additional precautions should be taken?	• Are the usual IPC measures effective? • If not or unsure, what additional precautions should be taken? • Are there unintended consequences?	• Information on incubation period, infectivity, routes of transmission, etc.
System response			

Category	What information is needed?		How will this be learned?
	Initial risk assessment	**Ongoing risk assessments**	
Public health	• What will be the potential impact?	• What is the impact on public health services and health human resources (HHR)? • Are they able to cope?	• Measures of transmissibility and virulence • Surveillance and clinical studies • PT feedback
Community health care	• What will be the potential impact?	• What is the impact on community health care services and HHR? • Are they able to cope?	• Measures of transmissibility and virulence • Surveillance and clinical studies • Information on antiviral resistance • PT feedback • Media monitoring
Acute care services	• What will be the potential impact?	• What is the impact on acute care services and HHR? • Are they able to cope? • What bacterial complications are occurring? • Are the treatment strategies effective?	• Measures of transmissibility and virulence • Surveillance and clinical studies • Information on antiviral and antibiotic resistance • Clinical studies • PT monitoring and feedback • Media monitoring
Long-term care and other community residential care	• Will long-term care or other residential facilities for the elderly or disadvantaged be at significant risk of outbreaks?	• What is the impact on these facilities, their services and HHR?	• Information on pre-existing immunity • Surveillance and outbreak investigations • PT feedback • Media monitoring

Category	What information is needed?		How will this be learned?
	Initial risk assessment	Ongoing risk assessments	
Societal impact	• Will there be significant workplace or school absenteeism? • Will community services be affected?	• What is the impact on schools, businesses, critical infrastructure and other community services? • What is the impact on vulnerable populations? • What is the psychosocial impact on the population? • What is the economic impact?	• Measures of transmissibility and virulence • School and workplace absenteeism surveillance • PT feedback • Media monitoring and public surveys • Clinician surveys • Qualitative studies
Risk communications	• What will be the level of public concern? • What issues will be of most concern?	• What are the levels of public concern? • What issues are of most concern and are we addressing them effectively? • What is the level of public awareness and understanding of the situation?	• Traditional and social media monitoring • Tracking of public inquiries • Public opinion research • Stakeholder feedback (PTs and NGOs)

Ontario Health Plan for an Influenza Pandemic

Chapter 4: Public Health Measures

Audience

- individuals responsible for developing, communicating and implementing public health measures within the provincial government, public health units (PHUs) and non-health organizations (e.g., boards of education, schools, summer camps and social service organizations)

Chapter objectives

- to define roles and responsibilities for developing and implementing public health measures during an influenza pandemic
- to describe the framework underlying the public health measures strategy
- to enable the public health sector and non-health organizations to develop and implement public health measures during an influenza pandemic

Public health measures response summary

Response objective: to slow the spread of influenza in Ontario using non-pharmaceutical methods

BEFORE SEVERITY IS KNOWN

Ministry of Health and Long-Term Care (MOHLTC) consults with local, provincial and federal partners to develop and rollout the public health measures strategy

PHUs develop and rollout local public health measures

Voluntary public health measures implemented; of the mandatory public health measures, only case & contact management is implemented

FIGURE 1. PUBLIC HEALTH MEASURES ACTIVITIES STRATIFIED BY SEVERITY

Introduction

Public health measures are non-pharmaceutical interventions that slow the spread of a communicable disease in a community. A key characteristic of public health measures is that they are implemented in non-health settings,[1] such as workplaces, homes, civic spaces (sports arenas, religious institutions), educational settings and community-based social services organizations. Public health measures are individual and group behaviours and the environmental supports that enable and encourage these behaviours. During an influenza pandemic, many people want to play an active role in making their community healthier; by implementing public health measures, everyone can contribute meaningfully to the influenza pandemic response.

Public health measures are commonly used across Ontario during the annual influenza season and other communicable disease outbreaks. Many public health measures used during an influenza pandemic are modifications of existing practices and therefore should be familiar to PHUs, non-health organizations and members of the public.

Roles and responsibilities

Table 1 outlines roles and responsibilities related to public health measures during an influenza pandemic. For a broad overview of roles and responsibilities during an influenza pandemic, see Chapter 1: Introduction.

TABLE 1. PUBLIC HEALTH MEASURES ROLES AND RESPONSIBILITIES

Party	Roles and responsibilities
Public Health Agency of Canada (PHAC)	Provide recommendations on public health measures to provinces and territories Develop and implement public health measures for populations under its jurisdiction (e.g., First Nation communities, members of the Canadian military, federal corrections facilities) Implement travel and border-related public health measures (travel advisories and restrictions, quarantine measures and border closures at international entry points)

[1] When these measures are used in health settings they are termed “infection prevention & control measures”; these measures are discussed in Chapter 5: Occupational Health & Safety and Infection Prevention & Control.

Party	Roles and responsibilities
MOHLTC[2] (through the Ministry Emergency Operations Centre (MEOC))	Develop the provincial public health measures strategy based on PHAC's recommendations and in consultation with provincial and local partners Develop and issue directives,[3] orders and requests as per the HPPA and other relevant provincial legislation Communicate the provincial public health measures strategy to PHUs, other health system partners and provincial ministries Communicate information on public health measures with the public Support PHUs and provincial ministries to implement public health measures in a wide range of settings Collaborate with Public Health Ontario (PHO) to evaluate and refine the provincial public health measures strategy
PHO (through the MEOC)	Provide scientific and technical advice to the MOHLTC Provide scientific and technical advice to PHUs to support the implementation of public health measures, such as developing tools and advising on best practices
Ministry of Labour (MOL)	Provide OHS advice to the MOHLTC (through the MEOC) Enforce the OHSA and its regulations
PHUs[4]	Provide advice to the MOHLTC to support the development, evaluation and refinement of the provincial public health measures strategy Develop, implement and evaluate public health measures based on the provincial strategy Develop and issue orders[5] as per the HPPA

[2] Throughout the OHPIP, the MOHLTC includes the Minister, the Chief Medical Officer of Health (CMOH) and the rest of the MOHLTC. For information on how decisions are made in the MOHLTC during an emergency, see the Ministry Emergency Response Plan.

[3] Directives are sent from the CMOH to health care providers or other health entities as per the Health Protection and Promotion Act (HPPA).

[4] Throughout the OHPIP, PHU includes boards of health, medical officers of health (MOHs) and other PHU health workers (e.g., public health inspectors, epidemiologists, public health nurses, etc.). See the HPPA and Ontario Public Health Standards for more information on the roles and responsibilities of various PHU parties.

Party	Roles and responsibilities
Employers in non-health organizations	Implement public health measures Role model public health measures Follow MOHLTC orders and requests Follow PHU orders
Public	Learn about and follow public health measures Follow MOHLTC and PHU orders

Voluntary and mandatory measures

Some public health measures are required under the HPPA and other provincial and federal legislation. Other measures are considered a best practice, but do not have the weight of legislation backing them. Because of this, public health measures can be categorized into two groups: voluntary public health measures (i.e., without the force of legislation) and mandatory public health measures (i.e., with the force of legislation). Appendix A provides an overview of voluntary and mandatory public health measures that may be implemented during an influenza pandemic.

Regardless of whether they are categorized as voluntary or mandatory, non-health organizations and the public should implement all recommended public health measures during an influenza pandemic.

Preparedness tip

Appendix B includes an overview of planning considerations for PHUs and non-health organizations to support the implementation of public health measures during an influenza pandemic.

Public health measures strategy

The provincial public health measures strategy cannot be finalized until the time of a pandemic as the type and relative significance of each measure depends upon the following factors:

- Evidence – The MOHLTC considers information on the severity of the pandemic, effectiveness of public health measures and the impact of other pandemic response activities (e.g., vaccine availability, effectiveness and uptake rates).
- Legislation – The strategy is based on legislative requirements and responsibilities.

---

[5] *This refers to orders made by MOHs and public health inspectors as per the HPPA.*

- Ontario Public Service (OPS) values and ethical principles[6] – The MOHLTC considers the OPS values and other ethical principles during the development of the strategy, including:
  - Proportionality: Restrictions on individual liberty and measures to protect the public from harm should not exceed the minimum required to address the actual level of risk or need in the community. The MOHLTC uses a risk-based approach to consider the proportionality of potential measures to the understood risks and impacts of the pandemic, especially for measures with significant social and economic consequences (e.g., school closures, mass gathering restrictions/ bans). Although some public health measures are easy for an individual to implement, others may involve behaviours that are not routine or that have limited direct benefit to an individual but are of benefit to society.
  - Reciprocity: Society has an ethical obligation to support those who face a disproportionate burden in protecting the public good.
- Health Equity – The MOHLTC considers the needs of vulnerable populations[7] when the public health measures strategy. The strategy strives to reduce or eliminate socially structured differentials in health outcomes, building on broader ideas about fairness, social justice and civil society. For example, the implementation of system-wide school closures has different impacts on groups in society such as single parents/ caregivers, children who participate in school-based nutrition programs, families with low or fixed incomes who cannot afford increased child care costs, and parents who do not have flexible work arrangements, paid vacation or short term leave policies.
- Communication principles – The MOHLTC considers its communication principles when developing the provincial strategy.[8] More restrictive measures require explanation from public health officials as to the reasons for these measures.

While the specifics of the strategy are not known, the public health measures strategy will include the following components:

---

[6] Work is underway federally to develop an ethical framework for the Canadian Pandemic Influenza Plan for the Healthcare Sector (CPIP). Future iterations of the Ontario Influenza Response Plan (OIRP) will include an ethical framework that aligns with the CPIP.

[7] The OHPIP defines vulnerable populations as a group of people who, because of the determinants of health, are more likely to be exposed to influenza, more likely to experience a serious impact because of exposure, less likely to benefit from response and recovery measures and/ or who may be negatively affected by response and recovery measures.

[8] The MOHLTC's communication principles include timeliness, transparency, accessibility and credibility.

- Guidance on adapting routine measures – The strategy will include guidance on how PHUs, non-health organizations and members of the public can adapt public health measures they routinely implement during seasonal influenza (see Table 2 for examples of how measures could be adapted).

TABLE 2. EXAMPLES OF ADAPTED PUBLIC HEALTH MEASURES

Activity	Example
Communication	PHUs identify additional public messaging opportunities Employers identify new locations for signage that reinforces specific measures (e.g., hand washing) PHUs make additional media buys to promote public health messages
Role modelling and reinforcement of measures	Boards of education and principals remind parents of the importance of keeping children home when ill Boards of education and principals review and update policies and procedures used when students are ill at school
Modifying and strengthening organization practices	Employers modify sick leave policies to ensure that employees are able to take time off work to care for ill family members Employers ensure there is more frequent cleaning of commonly touched surfaces
Social distancing	Employers extend work from home policies Shelters and daycares modify the placement of sleeping cots to ensure appropriate separation

- Focus on voluntary measures – As possible, the strategy will emphasize voluntary measures; however, mandatory measures may be recommended depending upon the risk posed by the influenza pandemic and the impact of other response activities.
- Environmental supports – The strategy will highlight the importance of ensuring environmental supports are in place to support non-health organizations and the public implement measures.
- Progression of the pandemic – As demonstrated in Table 3, some measures are more likely to be recommended at the beginning stages of an influenza pandemic (before the severity is known), while others are more likely to continue throughout the course of the event.

TABLE 3. ANTICIPATED TIMING OF PUBLIC HEALTH MEASURES

Measure	Beginning stages of the pandemic (before severity is known)	During the pandemic (understanding of severity evolves)
Voluntary public health measures	X	X
Case & contact management	X	
Orders		X

- Recognition of travel restrictions – The strategy will recognize travel restrictions recommended by PHAC, while noting the impact of orders under the HPPA on such restrictions.
- Local variation – The strategy will recognize opportunities for variation in local public health measures because of differences in disease activity, social context (e.g., role of public transit in the local community) and engagement practices (e.g., effective methods of communication for different communities, populations and environments).

Next steps

In the development of the OIRP, the MOHLTC will work with its partners to:

- develop guidance for PHUs on public communications
- engage non-health organizations on implementation of public health measures for influenza
- align the OIRP with the CPIP's ethical framework for decision-making

Appendix A – Sample public health measures

Influenza pandemic public health measures are a modification and intensification of existing good public health practices. Most measures are routinely implemented by PHUs, non-health organizations and the public during seasonal influenza outbreaks and are supported by the guidance provided in the Ontario Public Health Standards.

Public health measures can be organized into two categories: voluntary measures (i.e., measures without the force of legislation) and mandatory measures (i.e., measures with the force of legislation). All recommended public health measures should be fully implemented during an influenza pandemic.

Voluntary public health measures

Behaviours

Voluntary public health measures include the following individual and group behaviours:

- hand hygiene
- respiratory etiquette
- environmental cleaning, especially of frequently touched surfaces such as door handles
- illness isolation, which includes having individuals stay home when sick and implementing social distancing measures within the home when a household member is ill
- social distancing, which involves separation of people to minimize the likelihood of transmitting influenza
- closure of organizations or programs[9]

Environmental supports

During an influenza pandemic, it is critical to equip non-health organizations and the public with the supports they need to implement voluntary public health measures. Information, supportive workplace policies and role modelling are all important to the successful uptake voluntary measures.

---

[9] An organization may choose to suspend a program during an influenza pandemic because disease transmission cannot be adequately controlled and the program is not deemed to be critical.

Information

The information provided to non-health organizations and the public will help them implement voluntary behaviours and understand why these measures are important in helping to stop the spread of the influenza pandemic. Core elements include:

- information about the influenza pandemic, such as modes of transmission, risk and impacts
- information about public health measures, including why they are important and how to implement measures at home, in the workplace and elsewhere in the community

Support

In workplaces, supports may include adjustments to policies and procedures in order to help workers enact public health measures. Flexibility in sick leave policies as well as flexible work arrangements are examples of policies that support social distancing. Communication efforts should also be escalated so that changes to policies and procedures are widely understood and effectively implemented.

Role Modelling

Role modelling involves demonstrating behaviours so that the public can emulate them. Role modelling of public health measures by formal and informal leaders in society supports their adoption by normalizing the desired behaviours. Leaders such as school principals, teachers, employers and coaches should be encouraged to personally and publicly adopt these behaviours.

Mandatory public health measures

Mandatory public health measures are extraordinary actions designed to address and counter specific public health threats. Mandatory measures include case & contact management, orders and travel restrictions.

Case & contact management

Case management describes the method, and often formal protocol, where PHU staff follow-up with individuals ill with influenza (i.e., cases) to provide information and strategies to reduce transmission to others. The syndrome that defines a case is communicated through Important Health Notices. This definition may evolve during the influenza pandemic (e.g., during initial stages of the pandemic, the case definition may include travel history).

Contact management involves PHU staff identifying those who may have had close contact with infectious cases (i.e., contacts), notifying them and providing counselling and information to recognize emerging illness.

PHUs perform case & contact management during an influenza pandemic based on the provincial pandemic health measures strategy.

Orders

Authority exists under provincial and federal legislation to order the closure an organization for a period of time and/ or modify activities within an organization. The federal government may issue the closure of spaces under federal jurisdiction, as well as the exclusion of sick individuals from these spaces. The CMOH and MOHs may do the same for spaces under their jurisdiction as described by the HPPA. Organizations and individuals have the legal responsibility to comply with all orders issued by public health officials and to assist in their implementation.

There is other legislation that confers the responsibility for implementing public health measures to leaders outside of the public health sector. For example, the Education Act empowers principals to refuse school admission to those infected or exposed to communicable diseases. The Day Nurseries Act requires daycare operators to note the health status of children in their care, separate sick children from others, and require that parents/ guardians take sick children home.

Appendix B – Selected planning considerations

PHUs should consider in advance of a pandemic how public health measures could be implemented across their jurisdiction. Implementation of public health measures should be based on the PHU's extensive knowledge of their local context and community's needs, existing relationships with local partners, documentation of best practices for implementing public health measures during the annual influenza season and lessons learned from other health promotion activities.

Non-health care settings should similarly consider actions they can take to promote the uptake of public health measures during an influenza pandemic.

Environmental support of voluntary measures

To ensure maximum success, planning for the environmental support of voluntary public health measures should be undertaken by PHUs. This involves:

- audience segmentation and an analysis of appropriate modes of communication (including multilingual and accessible communication tools) for each audience, including vulnerable populations
- identifying the factors that influence and encourage the uptake of public health measures (which can be emphasized in communications)
- applying lessons learned from past experience with public health communications and health promotion programs

Leveraging existing relationships and routine interactions to teach, promote and reinforce the use of public health measures is important. An example is including hand washing lessons as part of a public health nurse's involvement in an Early Years program or as part of an after school program run by a community-based organization.

Closures

Non-health organizations should prepare for the implementation of closures during an influenza pandemic (e.g., school closures, closure of programs in social service organizations). An organization may need to close because of a mandatory public health measure issued by a public health official (e.g., order from the MOH to close the space or program due to the risk posed by the pandemic). However, an organization may also need to close as a result of other events during an influenza pandemic (e.g., the employer decides to close the space or program due to high rates of illness among employees or significant interruptions to public transportation systems).

Regardless of the reason, closures can affect continuity of operations (especially of critical services), employees, the population groups that the organization serves (e.g., students, customers) and secondary populations (e.g., parents of students).

As part of their planning, organizations should work closely with their PHU to better understand the HPPA and how orders under this act would be made and communicated during an influenza pandemic.

Organizations should consider times in the past when they have had to close because of events such as labour disruptions or inclement weather and identify lessons learned that could be applied to an influenza pandemic.

Appendix C – Selected practices from the 2009 influenza pandemic

Public health measures were effectively implemented in a wide range of non-health organizations during the 2009 H1N1 influenza pandemic. Some examples of best practices include the following:

- implementation of hand hygiene stations in arenas and recreation centres
- development of innovative activities to reinforce respiratory etiquette at summer camps and to modify existing policies and procedures to notify parents when campers were ill
- use of internal TV channels by correctional facilitates to share and reinforce educational messaging about the importance of implementing public health measures
- development of culturally appropriate education materials by PHUs for different population groups in their community
    - a PHU redeveloped their educational materials for a specific community that does not support the use of photographs of people – in the redeveloped materials, drawings of stick figures demonstrated how to implement public health measures
- development of strategic community-based communication programs by PHUs
    - a PHU intentionally engaged with leaders and 'information gatekeepers' to promote information about public health measures within their community more effectively
- development of targeted messaging based on community needs
    - a PHU reframed their educational messaging after engaging members from a migrant farm worker community
- development of strategies to implement public health measures in different business and industry settings, such as washing the steering wheels of delivery and service vans
- temporary suspension of some activities by schools and extracurricular programs, such as encouraging players not to shake hands after sports games - in many settings, the traditional handshake was replaced with a team cheer
- reorganization of programming and activities within social services organizations
    - a shelter for people who are homeless and underhoused encouraged guests and residents to sleep 'head to toe' (if in one bed the resident sleeps with their head pointing north, in the next bed, the resident would sleep with their head pointing south) to maintain social distancing measures

ACKNOWLEDGMENT OF EXPERT'S DUTY

---

1. My name is Dr. Richard Schabas. I live in Toronto, Ontario.

2. I have been engaged on behalf of the Moving Parties, Trinity Bible Chapel et al. and The Church of God, et al., to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

(c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

Date: May 29, 2021

Signature

NOTE: This form must be attached to any expert report under subrules 53.03(1) or (2) and any opinion evidence provided by an expert witness on a motion or application.

AFFIDAVIT OF DR. RICHARD SCHABAS
(Sworn July 23, 2021)

I, RICHARD SCHABAS, of the [redacted] in the Province of Ontario, MAKE OATH AND SAY:

1. I make this affidavit further to my affidavit sworn May 23, 2021, and in reply to the affidavit of Dr. Matthew Hodge, affirmed July 2, 2021.

2. Dr. Hodge states that Ontario's response to Covid-19, including decisions to interfere with religious gatherings, was guided by the "precautionary principle" which states that public health "does not await scientific certainty before taking action to protect" and that this is "particularly relevant during the early stages of a pandemic". He does not propose an alternative standard of evidence that would guide decision-making in these circumstances. This suggests that in his opinion little or no evidence is required before instituting coercive public health measures - that the "precautionary principle" effectively gives public health a blank cheque to do whatever it wants.

3. The traditional evidentiary standard for public health orders in Ontario, from the *Health Protection and Promotion Act*, is reasonable and probable grounds. This standard is not as demanding as the "scientific certainty" of the "precautionary principle", but it is still a high bar. With the exception of immunization, very few if any of the measures and none of the coercive measures used by Ontario public health in response to Covid-19 would meet the reasonable and probable grounds standard.

4. Dr. Hodge says the "burden model" informs his opinion, and that this model takes into account three factors - the prevalence of disease, exposure risk and consequences of infection. The inappropriateness of the "burden model" in advising this issue is obvious. It does not consider the consequences of the intervention.

5. The burden model may provide an appropriate perspective in the typical infectious disease outbreak where the control measures are targeted, reasonable and truly "temporary". Covid-19 and, more specifically, the public health response to Covid-19 are different because the measures taken undermine the fundamental determinants of health (education, employment, social connections) and are not, by any stretch of the imagination, short-lived. Reliance on the "burden model" goes

a long way to explaining the dysfunctional decision-making of Ontario public health.

6. Dr. Hodge's argument that Ontario has insufficient hospital beds to deal with Covid does not stand even rudimentary scrutiny. Ontario had almost 25,000 acute care hospital beds available for use as of April 2020.[1] At no point in the pandemic have Covid patients occupied even 10% of this number.[2] The maximum bed census for Covid-19 (2360 beds on April 20, 2021) was far less than the extra surge capacity (4205 beds) available in April 2020. One can only hope that the Ontario government, considering its concerns about health care capacity, has further enhanced this capacity in the past year. Dr. Hodge's threat of a "health system in which every available bed is occupied by someone infected with COVID-19" should be viewed in this context.

7. Dr. Hodge compares Ontario's overall mortality rate to three other jurisdictions with higher mortality (Sweden, Brazil and Florida) and attributes the difference to Ontario's interventions. This is common practice for defenders of lockdown. The world is a very large place, and it is easy to find anecdotal examples to support both sides of any argument.

8. Ontario and Canada as a whole have had low Covid mortality compared to most European countries, the United States or South America. The reasons for this are unclear. Ontario has indeed had lower Covid mortality than some jurisdictions that have been less coercive with Covid, but it has also had much lower mortality than many jurisdictions in Europe and the United States that have used more severe coercive measures.[3] We need look no further than Canada to see the paradox. British Columbia has been consistently less aggressive than Ontario with Covid control measures and yet has a mortality rate (352/million population) that is 55% lower than Ontario's (638/million population). At the present time there are no restrictions at all for religious services in British Columbia. And Quebec, which employed some of the most stringent measures of all has a death rate (1,321/million population) more than twice as high as Ontario.[4]

9. Dr. Hodge states “transmission risk seems to be highest prior to symptoms appearing, meaning that most infected people will unknowingly infect others before they themselves have symptoms”. He is referring to what is known as “pre-symptomatic transmission.” This statement is false and contrary to the reference he provides.

10. The general scientific consensus is that “most infected people” do not infect anyone. This is the “over-distributed” nature of Covid transmission.[5] The WHO reference provided by Dr. Hodge says, “Laboratory data suggests that infected people appear to be most infectious just before they develop symptoms (namely 2 days before they develop symptoms) and early in their illness.” With regard to people with asymptomatic infections, the WHO says, “While someone who never develops symptoms can pass the virus to others, it is still not clear how frequently this occurs and more research is needed in this area.”

11. Research has in fact been undertaken in the area of pre-symptomatic and asymptomatic transmission. A large, peer-reviewed meta-analysis of 54 studies conducted globally examined transmission from an infected person to another person living in the same home, where people do not wear masks or socially distance.[6] Studying transmission in the household setting gives the most accurate picture of how Covid will spread because of the lack of safeguards present. Symptomatic patients passed on the disease to household members in 18% of instances, while asymptomatic and pre-symptomatic patients passed on the infection in only 0.7% of instances. This makes sense, as the time-period during the pre-symptomatic phase (2 days prior to symptom onset) is relatively short and the symptoms themselves are a critical engine for spread. Covid transmission from patients without symptoms is rare and should not be used to justify restrictions on indoor gatherings.

12. I make this affidavit *bona fide.*

SWORN REMOTELY by videoconference by Dr. Richard Schabas at the [redacted] British Columbia, before me at the City of London, in the County of Middlesex, this 23rd day of July, 2021 in accordance with O.Reg. 431/20 Administering Oath or Declaration Remotely

A Commissioner, etc.

AFFIDAVIT OF DR. DAVID McKEOWN
(Affirmed on July 5, 2021)

I, **DAVID MCKEOWN,** of the [redacted], in the Province of Ontario, **AFFIRM:**

I. Professional Background

1. I am the Associate Chief Medical Officer of Health ("**ACMOH**") with the Ontario Ministry of Health. I have held that position since early 2020 and previously held that position from 2016 to 2017. I am a licensed physician in Ontario and have practiced medicine for 35 years. I have a medical degree from McGill University and a Master's degree in Community Health and Epidemiology from the University of Toronto. I am a certified specialist in Canada and the United States in the areas of public health and preventative medicine. Prior to being appointed ACMOH in 2016, I was the Medical Officer of Health for the City of Toronto for 12 years. Prior to the COVID-19 pandemic, I led local public health responses to the H1N1 pandemic, a major outbreak of Legionnaire's Disease, and the first outbreak of West Nile Virus in Canada.

2. Pursuant to section 81.1 of *Health Protection and Promotion Act*, my responsibilities as ACMOH include acting in the capacity of the Chief Medical Officer of Health when he is unavailable and performing such functions and duties as the Chief Medical Officer of Health may specify in writing. During the COVID-19 pandemic, my responsibilities have included monitoring the spread of COVID-19 in Ontario and advising on the Ontario Government's policy response to the pandemic.

3. As such, I have personal knowledge of the contents of this affidavit. Where in this affidavit I have indicated I have received information from others, I have identified the source of the information and I believe the information to be true.

II. Ontario's Policy Response to the COVID-19 Pandemic

(i) Legislative Background

4. On March 17, 2020, the Premier of Ontario declared an emergency pursuant to section 7.0.1 of the *Emergency Management and Civil Protection Act* ("***EMCPA***"). An "emergency" is defined under section 1 of *EMCPA* as a "situation or an impending situation that constitutes a danger of major proportions that could result in serious harm to persons or substantial damage to property and that is caused by the forces of nature, a disease or other health risk, an accident or an act whether intentional or otherwise."

5. The emergency was declared pursuant to O. Reg. 50/20, which was promulgated under *EMCPA*. That regulation stated that "the outbreak of a communicable disease namely COVID-19 coronavirus disease constitutes a danger of major proportions that could result in serious harm to persons" and that "an emergency is hereby declared pursuant to section 7.0.1 of the Act in the whole of the Province of Ontario." Under *EMCPA*, during a declared emergency, the Lieutenant

Governor in Council may make certain orders that it believes are necessary to address the emergency, subject to the conditions set out in *EMCPA*.

6. On March 24, 2020, O. Reg. 82/20 was promulgated pursuant to the emergency powers under *EMCPA*. Pursuant to that regulation, all non-essential businesses were ordered to close and limits were placed on the operations of other businesses and organizations. Since March 24, 2020, O. Reg. 82/20 has been amended regularly as the pandemic has evolved. In addition, several other orders have been made under *EMCPA* to address the COVID-19 pandemic.

7. Under *EMCPA*, declarations of emergency (and the powers associated with them) are intended to be time limited. In order to ensure the Lieutenant Governor in Council continued to have the power to address the ongoing effects of the pandemic after the emergency declaration terminated, the Legislature enacted the *Reopening Ontario (A Flexible Response to COVID-19) Act, 2020* ("***ROA***"), which was proclaimed into force on July 24, 2020. The *ROA* terminated the provincial emergency and continued a number of orders made under *EMCPA* that were designed to address the COVID-19 pandemic, including O. Reg. 82/20. Since the *ROA* was passed, the Province has amended several orders that were continued under the *ROA* and taken a variety of other public health measures to address the ongoing pandemic.

8. On April 27, 2020, Ontario released its *Framework for Reopening our Province*, which established criteria that Ontario's Chief Medical Officer of Health and other health experts would use to advise the government on the loosening of emergency measures, as well as guiding principles for the safe, gradual reopening of businesses, services and public spaces. The plan contemplated a stage-by-stage approach to reopening the economy.

9. At that time, areas of the province were subject to different restrictions as they moved through three stages of reopening:

- **Stage 1:** Select businesses that were ordered to close or restrict operations would be permitted to reopen with modified operations. Some outdoor spaces, such as parks, would reopen to allow for a greater number of individuals to attend some events (O. Regs. 82/20; O. Reg. 52/20; and O. Reg. 104/20).
- **Stage 2:** More businesses would be permitted to reopen based on risk assessments, more outdoor spaces would reopen, and some larger public gatherings would be permitted (O. Reg. 263/20).
- **Stage 3:** Opening of all workplaces and further relaxing of restrictions on public gatherings (O. Reg. 364/20).

(ii) The Keeping Ontario Safe and Open Framework

10. On November 3, 2020, Ontario released its *Keeping Ontario Safe and Open Framework* ("*Framework*"), which established a modified tiered approach to combatting the pandemic. The *Framework* was intended to allow the province to scale up and scale back public health restrictions on a regional basis in response to surges and waves of COVID-19. It provided a more tailored approach that allowed measures and restrictions to be increased or decreased as required by local epidemiological data.

11. The *Framework* created five zones of public health protection measures, each with varying levels of public health protection measures. The five zones were (1) Green-Prevent; (2) Yellow-Protect; (3) Orange-Restrict; (4) Red-Control; and (5) Grey-Lockdown. Attached as **Exhibit "A"** is a press release dated November 3, 2020, entitled "Ontario Releases COVID-19 Response Framework to Help Keep the Province Safe."

12. The regulations that originally implemented the three stages were amended as follows to implement the various zones:

Zone	Applicable Regulation
Green-Prevent	O. Reg. 364/20
Yellow-Protect	O. Reg. 364/20
Orange-Restrict	O. Reg. 364/20
Red-Control	O. Reg. 263/20
Grey-Lockdown	O. Reg. 82/20

Each of the above-noted regulations has been amended multiple times since the *Framework* was first implemented to respond as needed to the changing COVID-19 situation.

13. Pursuant to O. Reg. 363/20, the Ontario can designate which geographic areas in the province are subject to which level of public health protection measures. The *Framework* provided that several public health indicators would inform any adjustment or tightening of health measures, including weekly incidence of COVID-19, the test positivity rate, the effective reproduction number (Rt), evidence of recent outbreaks, and the level of community transmission.

14. More generally, Ontario's approach to the pandemic has been informed by public health data and by public health professionals. Ontario's priorities when developing the *Framework* included limiting the transmission of COVID-19, avoiding closures while reducing the risk of transmission, keeping schools and childcare open and safe, maintaining health care and public health system capacity, protecting vulnerable populations, and providing additional support to those disproportionately affected by the pandemic.

15. In November and December 2020, Ontario moved various regions into different levels in the *Framework*, depending on the state of the pandemic in those regions. For example:

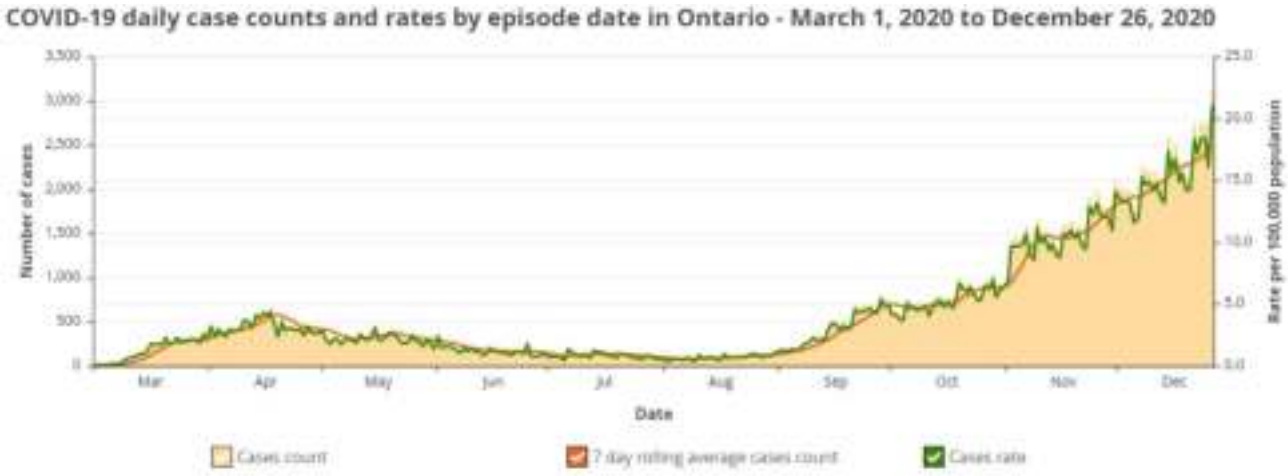
- On November 7, 2020, Peel Region was moved into Red-Control, the second-highest level in the framework. At the request of the local medical officer of health, Toronto remained in a modified Stage 2 under the previous framework.

Attached as **Exhibit "B"** is a press release dated November 6, 2020, entitled "Ontario Moves Public Health Unit Regions into COVID-19 Response Framework to Keep Ontario Safe and Open."

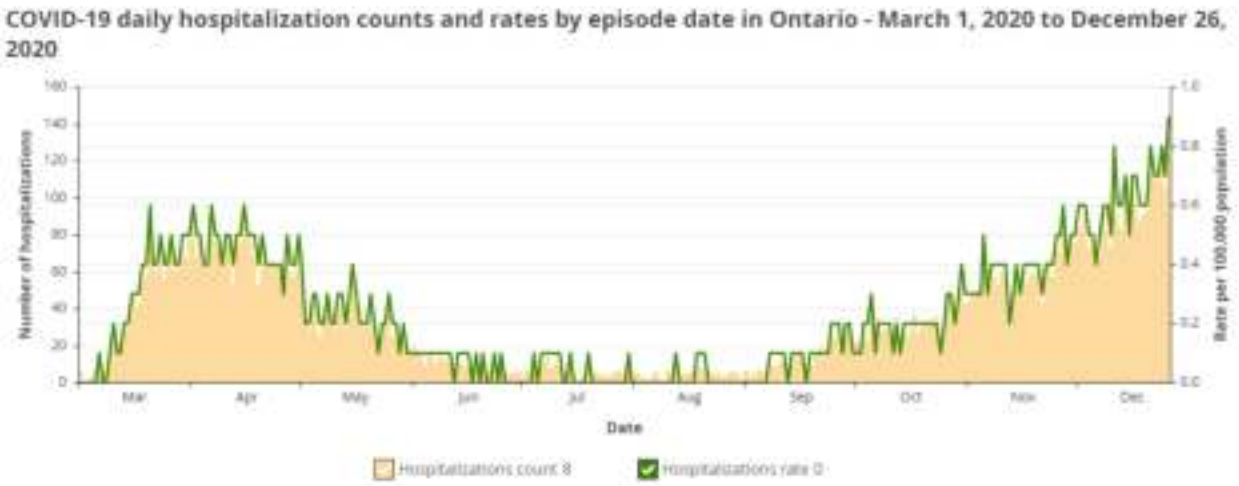
- On November 14, 2020, Toronto, Hamilton, Halton Region, and York Region moved into Red-Control. Attached as **Exhibit "C"** is a press release dated November 13, 2020, entitled "Ontario Updating COVID-19 Response Framework to Help Stop the Spread of COVID-19."
- On November 23, 2020, the City of Toronto and the Region of Peel were moved into Grey-Lockdown, which was at that time the highest level in the framework. Attached as **Exhibit "D"** is a press release dated November 20, 2020, entitled "Ontario Taking Further Action to Stop the Spread of COVID-19."
- On November 30, 2020, Windsor-Essex County Health Unit was moved into Red-Control. Attached as **Exhibit "E"** is a press release dated November 27, 2020, entitled "Ontario Moving Regions to New Levels in COVID-19 Response Framework."
- On December 14, 2020, Windsor-Essex County Health Unit and York Region Health Unit were moved into Grey-Lockdown. Attached as **Exhibit "F"** is a press release dated December 11, 2020, entitled "Ontario Moving Regions to New Levels with Stronger Public Health Measures."

(iii) The Second Provincial State of Emergency

16. In December 2020, there was a significant increase in COVID-19 cases and hospitalizations in Ontario. The graph below from Public Health Ontario ("**PHO**") shows daily COVID-19 cases in Ontario from March 1, 2020 to December 26, 2020:



17. Below is a graph from PHO that shows the number of daily COVID-19 hospitalizations in Ontario from March 1, 2020 to December 26, 2020:



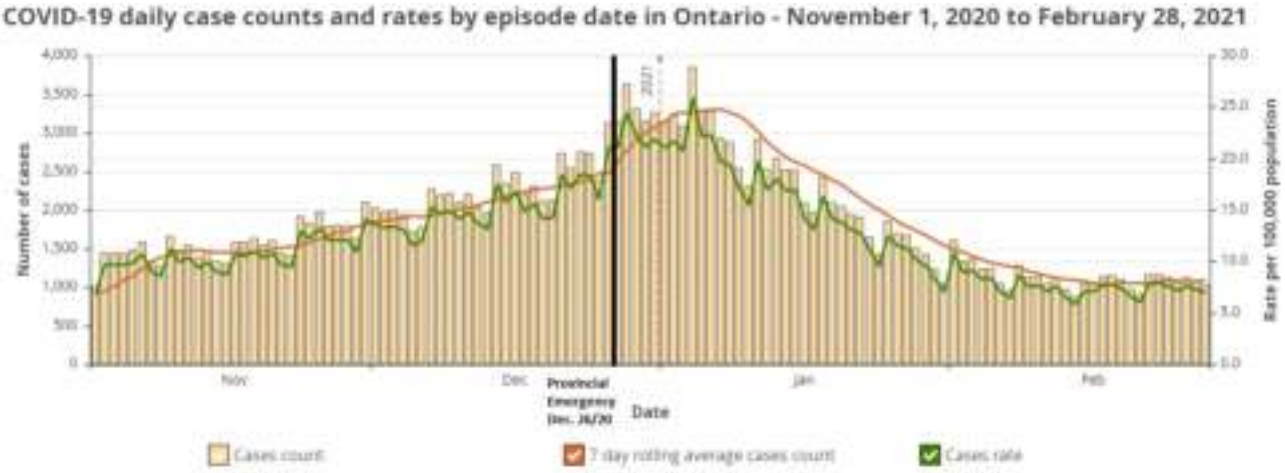
18. On December 21, 2020, the worsening COVID-19 situation led the government to pause the *Framework* and implement a Provincewide Shutdown effective December 26, 2020. Attached as **Exhibit "G"** is a press release dated December 21, 2020, entitled "Ontario Announces Provincewide Shutdown to Stop Spread of COVID-19 and Save Lives."

19. On January 12, 2021, the Premier of Ontario declared a second province-wide state of emergency pursuant to O. Reg. 7/21, which was promulgated under section 7.0.1 of *EMCPA*. The

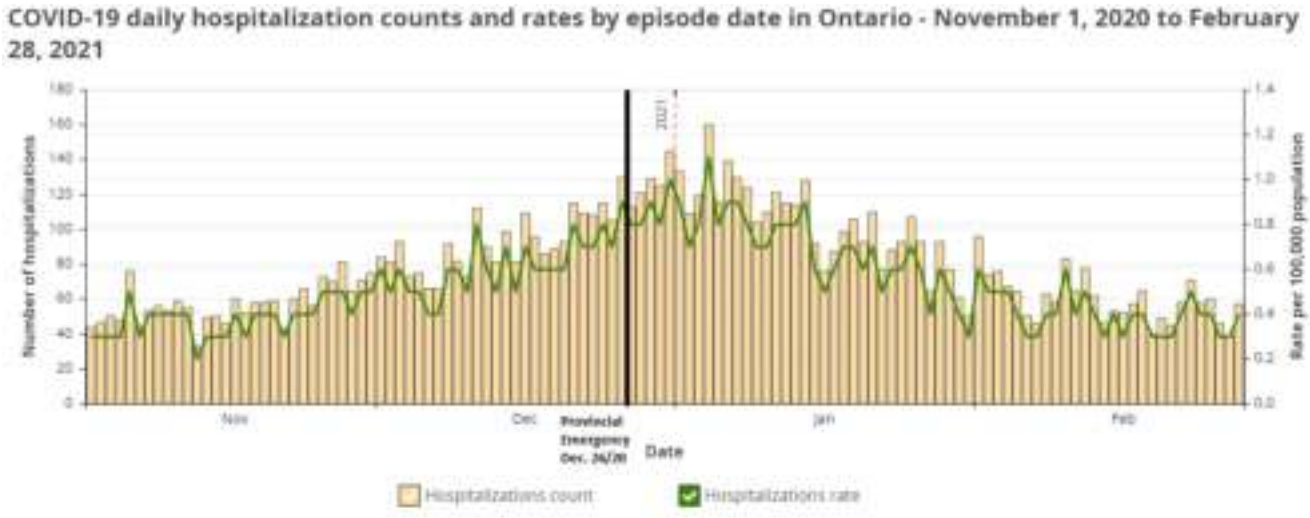
declaration of a state of emergency followed significant increases in the number of COVID-19 cases, hospitalizations and ICU patients in Ontario. Attached as **Exhibit "H"** is a press release dated January 12, 2021, entitled "Ontario Declares Second Provincial Emergency to Address COVID-19 Crisis and Save Lives."

20. During the state of emergency, the *Framework* was temporarily suspended and more stringent measures were put in place province-wide. Among other measures, the Province issued a stay-at-home order requiring everyone to remain at home, with exceptions for certain permitted purposes or activities, such as going to the grocery store or pharmacy, accessing health care services, or performing work that cannot be done remotely. In addition, schools moved to teacher-led remote learning until January 11, 2021 in Northern Ontario, January 25, 2021 in most of Southern Ontario, and February 10, 2021 in the most-affected regions such as Toronto.

21. Shortly after the province implemented the second state of emergency, COVID-19 cases in Ontario began to level off and then steadily decline. According to data from PHO, on December 26, 2021, the rolling 7-day average of new COVID-19 cases in Ontario was 2,488. By February 9, 2021, that number had declined to 1,210. Below is graph from PHO showing the number of new COVID-19 cases in Ontario from November 1, 2020 to February 28, 2021:



22. There was a similar decline in the number of hospitalizations. Below is a graph from PHO showing daily hospitalizations from November 1, 2020 to February 28, 2021:



23. At that time, very few Ontarians had received any COVID-19 vaccinations, as Ontario's vaccine rollout was hampered by a lack of a stable and reliable supply of vaccines from the federal government. According to data from PHO, throughout the entire second state of emergency, less than 2% of the Ontario population had received even a first dose of the vaccine and less than 1% were fully vaccinated.

24. Following a significant decline in COVID-19 cases, the second provincial state of emergency ended on February 9, 2021. At that time, the Province began to gradually transition regions throughout the province from the emergency shutdown measures to revised measures under the *Framework*, as the public health situation in those regions permitted.

25. At the same time, Ontario introduced an "emergency brake" system to allow for immediate action if a public health unit experienced rapid acceleration in COVID-19 transmissions or if its health care system risked being overwhelmed. If that occurred, the Chief Medical Officer of Health, in consultation with the local Medical Officer of Health, could recommend immediately

moving a region into Grey-Lockdown to interrupt transmission. Attached as **Exhibit "I"** is a press release dated February 8, 2021, entitled "Ontario Extending Stay-at-Home Order across Most of the Province to Save Lives."

26. In February and March 2021, Ontario moved various regions into and out of various levels of public health protections, depending on the state of the pandemic in those regions. For example:

- On February 16, 2021, twenty-seven public health regions transitioned out of the shutdown into the revised *Framework*. Four public health regions – City of Toronto, Peel Region, York Region, and North Bay Parry Sound District Health Units – remained in the shutdown in light of the continuing severity of the COVID-19 situation in those regions. Attached as **Exhibit "J"** is a press release dated February 12, 2021, entitled "Ontario Returning 27 Public Health Regions to Strengthened COVID-19 Response Framework."
- On February 22, 2021, York Region returned to the *Framework*, but COVID-19 rates remained too high in the other three regions to justify a similar return to the *Framework*. As well, variants of concern ("VOCs") were starting to spread in the community, particularly in North Bay. Attached as **Exhibit "K"** is a press release dated February 19, 2021, entitled "Stay-at-Home Order Extended in Toronto and Peel Public Health Regions Along with North Bay-Parry Sound"
- On March 1, 2021, Ontario activated the "emergency brake" and returned Thunder Bay District and Simcoe-Muskoka District Health Units to Grey-Lockdown in order to immediately interrupt transmission and contain community spread of VOCs in those regions. Attached as **Exhibit "L"** is a press release dated

February 26, 2021, entitled "Ontario Activates Emergency Brake in Thunder Bay District Health Unit and Simcoe-Muskoka District Health Unit."

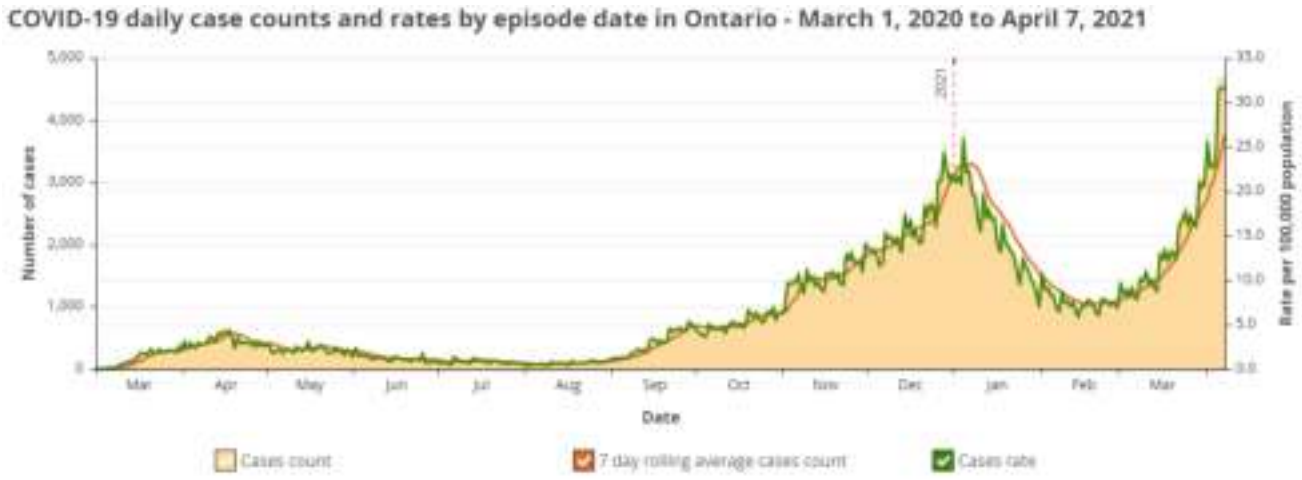
- On March 8, 2021, there was evidence of some improvement in the COVID-19 situation, which permitted the return of Toronto, Peel, and North Bay Parry Sound to the *Framework*. North Bay Parry Sound District Health Unit returned at the Red-Control level. Toronto and Peel, despite making progress, still had higher case rates and returned at the Grey-Lockdown level. Attached as **Exhibit "M"** is a press release dated March 5, 2021, entitled "Toronto, Peel and North Bay-Parry Sound Public Health Regions Returning to Strengthened COVID-19 Response Framework."
- On March 12, 2021, Ontario again activated the "emergency brake" and moved Sudbury District Health Unit to Grey-Lockdown due to a rapid rise in the case rate in that area. Attached as **Exhibit "N"** is a press release dated March 11, 2021, entitled "Ontario Activates Emergency Brake in Sudbury Public Health Region."

(iv) The Third Provincial State of Emergency

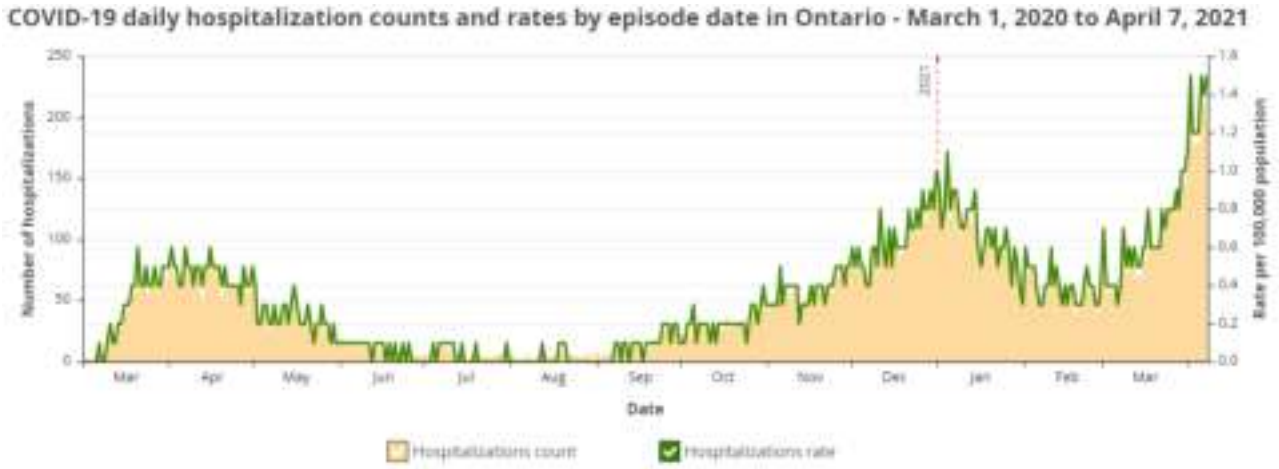
27. In March and April 2021, COVID-19 cases and hospitalizations in Ontario increased rapidly. On March 1, 2021, the average number of new COVID-19 cases reported each day based on a 7-day rolling average was 1,113. By April 1, 2021, the 7-day rolling average of new cases per day had increased to 3,327. By April 12, 2021, that number reached 4,484. By mid-April 2021, there were more patients hospitalized in Ontario as a result of COVID-19 than at any time since the start of the pandemic. Attached as **Exhibit "O"** is an Update on COVID-19 Projections dated April 1, 2021, from the Ontario COVID-19 Science Advisory Table, a group of health

professionals that evaluates and reports on emerging evidence relevant to the COVID-19 pandemic.

28. Below is a graph from PHO of daily COVID-19 cases from March 1, 2020 to April 7, 2021, which shows a significant increase in cases in March and April 2021:



29. The number of hospitalizations followed a similar trend. Below is a graph from PHO that shows daily COVID-19 hospitalizations in Ontario from March 1, 2020 to April 7, 2021:



30. On April 1, 2021, the alarming surge in case numbers and COVID-19 hospitalizations across the province led Ontario, in consultation with the Chief Medical Officer of Health and other

health experts, to implement a provincewide "emergency brake," effective April 3, 2021. Provincial case rates had increased by 7.7% to 101.1 cases per 100,000 people, COVID-19 related ICU admissions had exceeded the peak of the second wave, and hospitals in regional hotspots were beginning to further ramp down scheduled surgeries. Attached as **Exhibit "P"** is a press release dated April 1, 2021, entitled "Ontario Implements Provincewide Emergency Brake."

31. All 34 public health units were moved into the Shutdown Zone. The public health measures applicable in the Shutdown Zone included prohibiting indoor organized public events and social gatherings and limiting the capacity for outdoor organized public events or social gatherings to a 5-person maximum, except for gatherings with members of the same household or of one household and one other person from another household who lives alone. Capacity at weddings, funerals, and religious services, rites or ceremonies was limited to 15% occupancy per room indoors and to the number of individuals who could maintain 2-metre physical distancing outdoors. Ontarians were asked to limit trips outside the home, except for necessities.

32. On April 7, 2021, the Premier of Ontario declared a third province-wide state of emergency pursuant to O. Reg. 264/21, which was promulgated under section 7.0.1 of *EMCPA*. This state of emergency was implemented following rapid increases in COVID-19 cases, hospitalizations, and ICU occupancy in Ontario. For example, the number of COVID-19 hospitalizations in the province increased by 28.2% between the period of March 28 and April 5, 2021. In addition, between March 28 and April 5, 2021, the number of COVID-19 patients in ICUs increased by 25%. There was also an increase in the number of cases that were identified as VOCs, as discussed above. Attached as **Exhibit "Q"** is a press release dated April 7, 2021, entitled "Ontario Enacts Provincial Emergency and Stay-at-Home Order."

33. During this state of emergency, the entire province was in the Shutdown Zone and subject to the health protection measures set out in in O. Reg. 82/20, as well as additional measures, such as a stay-at-home order promulgated under *EMCPA*.

34. The health protection measures that applied during the third state of emergency included:

- the province-wide stay-at-home order, requiring everyone to remain at home except for essential purposes, such as going to the grocery store, accessing health care services, engaging in outdoor exercise, or conducting work that cannot be done remotely;
- limiting the majority of non-essential retailers to curbside pick-up and delivery only;
- restricting access to shopping malls to limited specified purposes;
- restricting discount and big box stores in-person retail sales to essential items;
- imposing more restrictive capacity limits for business or facilities that remain open to the public; and
- limiting restaurants and bars to providing take-out, delivery and drive-through service only.

35. On April 12, 2021, the Province moved elementary and secondary schools to remote learning following the April Break to limit community transmission, take pressure off hospitals, and allow more time to rollout further COVID-19 vaccinations. Attached as **Exhibit "R"** is a press release dated April 12, 2021, entitled "Ontario Moves Schools to Remote Learning Following Spring Break."

36. By April 16, 2021, COVID-19 cases, hospitalizations and ICU occupancy were at their highest levels since March 2020. Attached as **Exhibit "S"** is a graph from the Ontario COVID-19

website showing the number of patients hospitalized and in ICUs in Ontario with COVID-19 from April 2, 2020 to July 5, 2021. Attached as **Exhibit "T"** is an Update on COVID-19 Projections dated April 16, 2021, from the Ontario COVID-19 Science Table.

37. The number of hospitalized patients in an ICU due to COVID-19 also increased significantly. The increase in ICU patients was particularly concerning because it not only threatened the ability of the healthcare system to deal with COVID-19 patients, it also compromised the ability of the healthcare system to care for regular (i.e. non-COVID-19) patients. Attached as **Exhibit "U"** is a table showing the number of COVID-19 cases in ICU and ICU occupancy in Ontario as of April 18, 2021.

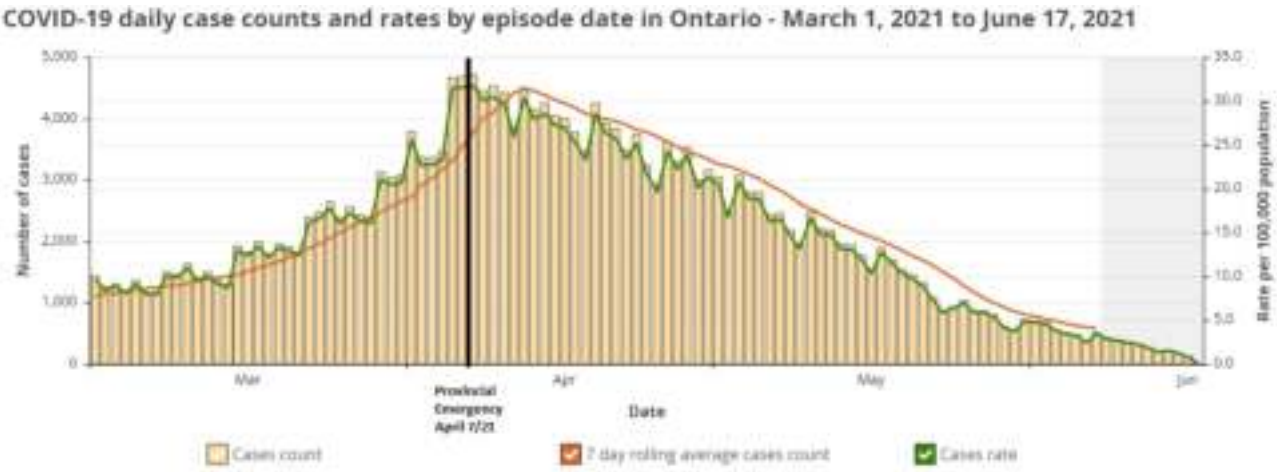
38. Beginning on April 16, 2021, the Province started to implement additional health protection measures, including the following:

- Indoor or outdoor gatherings (other than religious, wedding or funeral services) were only permitted with members of the same household or one other person from outside that household who lives alone or who is a caregiver for any member of the household.
- Indoor or outdoor religious, wedding and funeral services were limited to a maximum of 10 people. Drive-in religious, wedding and funeral services were permitted without any capacity limits.
- Retail stores where in-store shopping was permitted (e.g. supermarkets, grocery stores, convenience stores, indoor farmers' markets, other stores that primarily sell food and pharmacies) were required to operate at no greater than 25% capacity.
- Outdoor recreational amenities, such as golf courses, basketball courts, and soccer fields, were required to close.

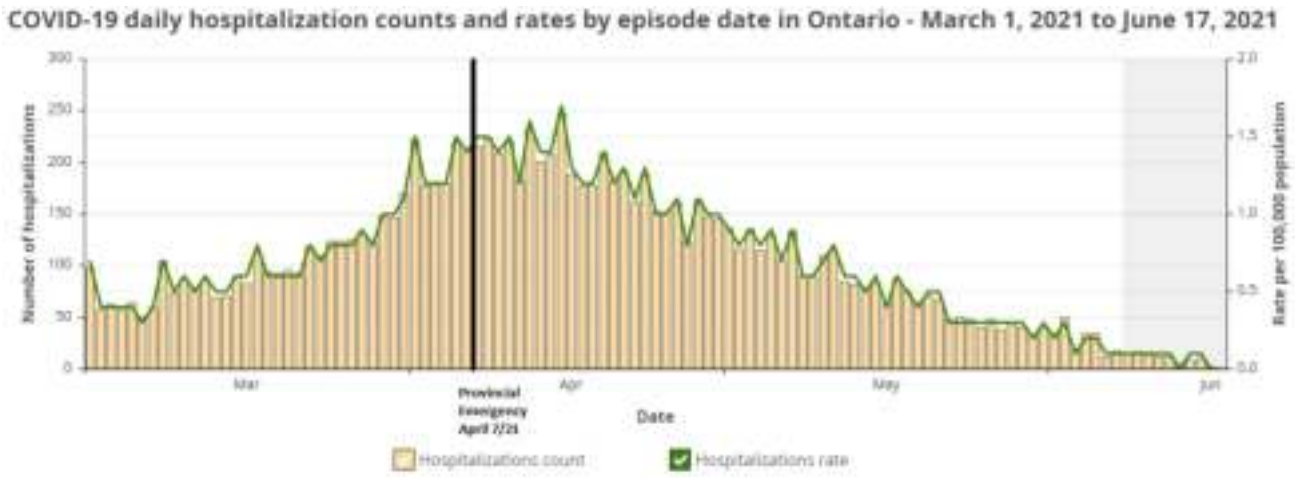
39. In addition, the government restricted travel into Ontario from neighbouring provinces, except for essential purposes, such as work, health care services, transportation of goods, or exercising Aboriginal or treaty rights.

(v) The Reopening Ontario Roadmap

40. Shortly after the Province declared a state of emergency on April 7, 2021, COVID-19 cases in Ontario began to decline. The 7-day rolling average number of daily new cases peaked on April 12, 2021, at 4,484, after which it began to steadily decline. Below is a graph from PHO showing daily new COVID-19 cases in Ontario from March 1, 2021 to June 17, 2021:



41. At the same time, there was a steady decline in the number of hospitalizations. Below is a graph from PHO that shows the number of daily new hospitalizations from COVID-19 from March 1, 2021 to June 17, 2021:



42. The decline in cases and hospitalizations was occurring at a time when the percentage of the Ontario population that had received a COVID-19 vaccine was still relatively low. According to data from PHO, when the Province implemented the third state of emergency on April 7, 2021, less than 3% of the Ontario population was fully vaccinated and only 17% of the population had received a first dose of vaccine.

43. By May 20, 2021, the number of COVID-19 cases had fallen significantly, with the 7-day rolling average of daily new cases dropping to 1,768, down from a high of 4,484 cases on April 12, 2021. Due to the declining number of cases and improvements in other key public health measures, such as hospitalization and ICU capacity, the Ontario government announced a three-step plan to safely reopen the province and end the province-wide stay-at-home order (the "*Roadmap*"). Attached as **Exhibit "V"** is a press release dated May 20, 2021 entitled "Ontario Releases Three-Step Roadmap to Safely Reopen the Province."

44. The *Roadmap* outlines three steps to easing public health measures, which were guided by the following principles:

- **Step 1:** An initial focus on resuming outdoor activities with smaller crowds where the risk of transmission was lower and some retail was permitted with restrictions.

This step included allowing outdoor gatherings of up to ten people, outdoor dining with up to four people per table, and non-essential retail at 15% capacity. Religious services, rites and ceremonies were permitted indoors at 15% capacity and outdoors with the only capacity limit being that participants had to be able to physically distance at least 2 metres. Drive-in religious services, rites and ceremonies were permitted without any capacity limits.

- **Step 2:** Further expanding outdoor activities and resuming limited indoor services with small numbers of people where face coverings are worn, including outdoor gatherings of up to 25 people, outdoor sports and leagues, personal care services where face coverings can be worn and with capacity limits. Religious services, rites and ceremonies are permitted indoors at 25% capacity and outdoors with the only capacity limit being that participants must be able to physically distance at least 2 metres. Drive-in religious services, rites and ceremonies are permitted without any capacity limits.
- **Step 3:** Expanding access to indoor settings, with restrictions, including allowing larger numbers of people in gatherings indoors where face coverings can't always be worn. This will include indoor sports and recreational fitness, indoor dining, museums, art galleries and libraries, and casinos and bingo halls, with some capacity limits. Religious services, rites and ceremonies will be permitted indoors at a capacity which will allow physical distancing .

45. The Reopening Roadmap states that the decision of when to proceed to the next step will be informed by several public health and health system indicators. One of those indicators is the

level of vaccinations in Ontario. The Reopening Roadmap provides that Ontario will not proceed to the next step of reopening until the following vaccinations thresholds have been met:

- **Step 1:** 60% of adults vaccinated with one dose.
- **Step 2:** 70% of adults vaccinated with one dose and 20% vaccinated with two doses.
- **Step 3:** 70% to 80% of adults vaccinated with one dose and 25% vaccinated with two doses.

46. While vaccination rates are a key public health measure that informs Ontario's decision to proceed through the steps of the Reopening Roadmap, they are not the only measure. Other important considerations include the number of hospitalizations, ICU occupancy and the weekly case incidence rates. It should be noted that the protective effects of the vaccine (for both the first and the second dose) take several weeks to develop. It should also be noted that, while the approved COVID-19 vaccines have been shown to be effective in preventing symptomatic illness, the evidence is less clear on the degree to which vaccines prevent asymptomatic transmission. A single dose of vaccine does not provide complete protection against symptomatic illness. Attached as **Exhibit "W"** is a publication from PHO dated April 15, 2021, entitled "Considerations for Public Health Measures for Individuals with Partial Vaccination for SARS-CoV-2."

47. On May 22, 2021, based on the provincewide vaccination rates and improvements in key public health indicators, Ontario lifted the temporary prohibition on some outdoor amenities, including golf courses, soccer fields, tennis and basketball courts, and skate parks. Those outdoor activities were permitted, provided physical distancing could be maintained. No outdoor sports or recreational classes were permitted at that time. Outdoor limits for social gatherings and organized public events were expanded to five people, including with members of different households. All

other public health and workplace safety measures under the provincewide emergency brake remained in effect.

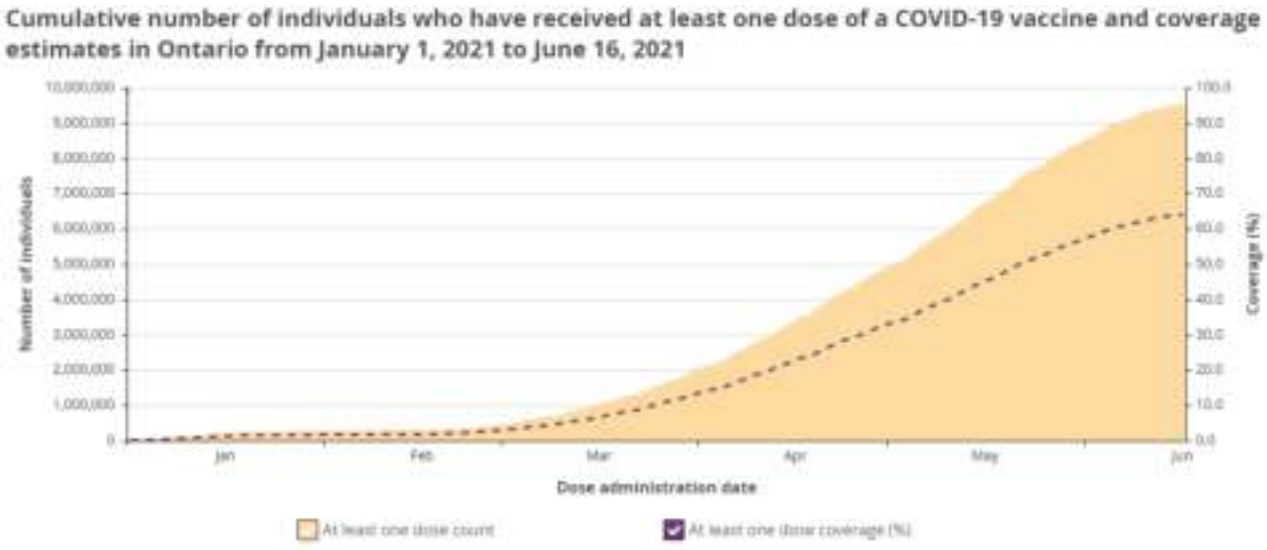
48. On June 2, 2021, based on the provincewide vaccination rates and improvements in key public health indicators, the province-wide stay-at-home order was lifted. All other public health measures existing at that time remained in place, including the restrictions imposed by the third state of emergency order. Attached as **Exhibit "X"** is a press release dated June 1, 2021, entitled "Ontario Maintains COVID-19 Restrictions as Stay-at-Home Order is Set to Expire."

49. On June 9, 2021, based on province-wide vaccination rates and improvements in other key public health indicators, Ontario ended the third state of emergency. On June 11, 2021, the province moved into Step 1 of the *Roadmap*. At that time, the number of cases and hospitalizations were steadily decreasing and over 72% of Ontario adults had received a first dose of a COVID-19 vaccine. There were still 494 patients in Ontario ICUs due to COVID-19, but that number was down from a high of over 800 patients in ICUs in April 2020. Attached as **Exhibit "Y"** is an Update on COVID-19 Projections dated May 20, 2021, from the Ontario COVID-19 Science Table.

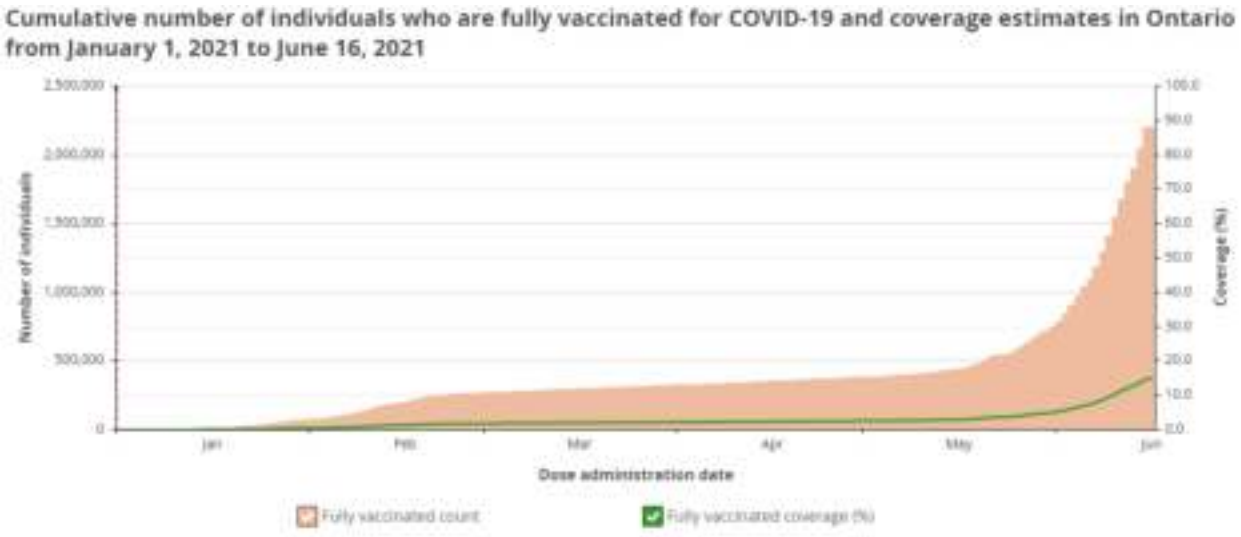
50. Due to high rates of COVID-19 transmission locally, including a rise in the number of cases involving the Delta variant, the Medical Officer of Health for the Porcupine Public Health Unit issued a series of instructions requiring businesses and organizations in the Porcupine Health Unit region to implement enhanced public health measures, beyond those required at Steps 1 and 2 of the Roadmap. The regulations that apply at each Step of the Roadmap state that a person responsible for a business or organization must operate that business or organization in compliance with instructions of public health officials, which includes instructions issued by local Medical

Officers of Health. Attached as **Exhibit "Z"** are the instructions issued by the Porcupine Medical Officer of Health.

51. On June 30, 2021, after having reached the vaccination target of 70% of adults with one dose and 20% of adults with two doses for at least two weeks and with other key public health measures, including hospitalizations, ICU occupancy, and weekly case incidence rates, improving, Ontario moved to Step 2 of the Reopening Roadmap. Below is a graph from PHO showing the number of individuals and rate of first dose vaccinations from January 1, 2021 to June 16, 2021:



52. Below is a graph from PHO showing the number of individuals and rate of second dose vaccinations from January 1, 2021 to June 16, 2021. As noted below, second dose vaccinations did not begin to significantly increase until approximately mid-June 2021. Prior to June 2021, only approximately 3% of Ontarians had received a second dose and most of those individuals were in nursing or long-term care facilities.



53. Step 2 focuses on the resumption of more outdoor activities and limited indoor services with small numbers of people where face coverings are worn, with other restrictions in place. The public health measures applicable at Step 2 include:

- Outdoor social gatherings are permitted up to 25 people;
- Indoor social gatherings are permitted with up to 5 people;
- Indoor religious services, rites or ceremonies are permitted with up to 25% capacity of each particular room. Outdoor religious services, rites or ceremonies continue to be permitted with the only capacity limit being that participants must be able to physically distance at least 2 metres. Drive-in religious services, rites and ceremonies continue to be permitted without any capacity limits;
- Personal care services where face coverings can be worn are permitted at 25% capacity;
- Outdoor sport facilities with spectators are permitted at 25% capacity;
- Outdoor fairs, rural exhibitions and festivals are permitted at 25% capacity;
- Outdoor concert venues, theatres and cinemas are permitted at 25% capacity;

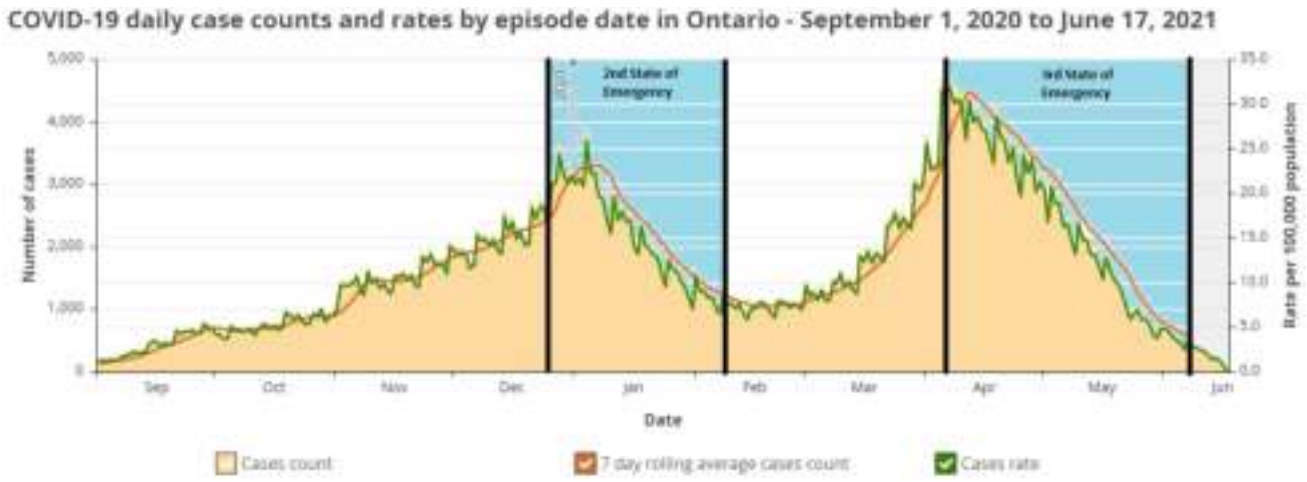
- Essential and other select retail is permitted up to 50% capacity while non-essential retail is permitted up to 25% capacity.

54. On June 29, 2021, the Medical Officer of Health for the Region of Waterloo, Dr. Hsiu-Li Wang, issued instructions, effective June 30, 2021, requiring the Region of Waterloo to maintain Step 1-level restrictions after entering Step 2 with the rest of the province on June 30, 2021. Dr. Wang stated that these measures were necessary due to the high prevalence of the Delta variant in the Region. It is anticipated that these measures will be necessary until approximately mid-July 2021. Attached as **Exhibit "AA"** are the instructions issued by the Waterloo Medical Officer of Health.

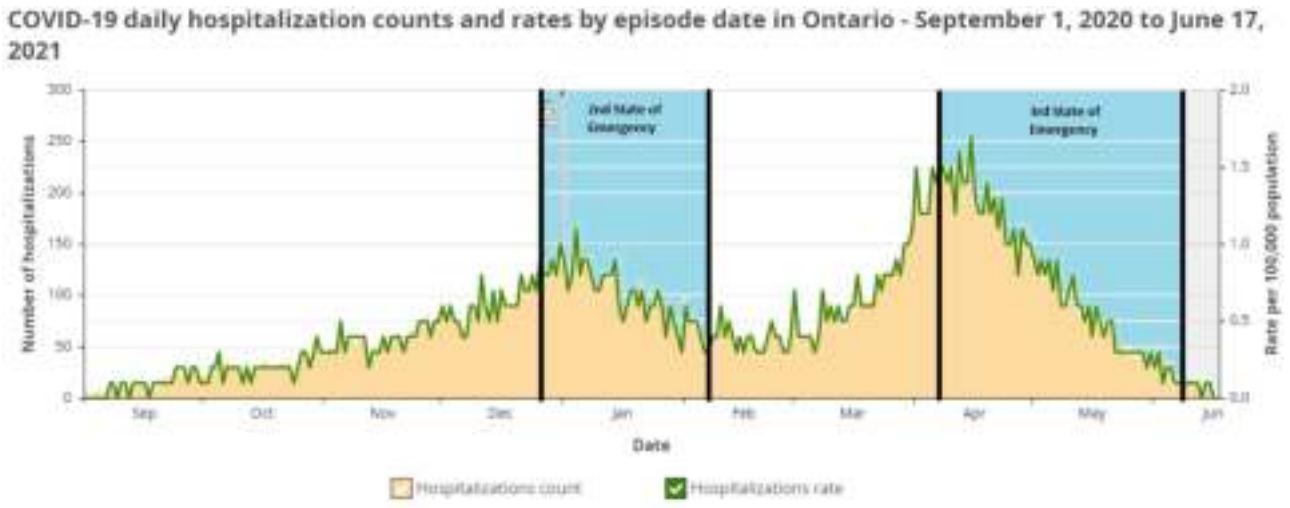
III. The Impact of Ontario's Public Health Measures

55. The public health measures implemented by Ontario had a significant impact on decreasing the transmission of COVID-19 across the province and reducing the strain on the healthcare system. Among other things, the implementation of public health measures during the second and third states of emergency were shortly followed by a substantial decrease in the number of COVID-19 cases and hospitalizations.

56. Both the second and third states of emergency were implemented at times when the number of daily COVID-19 cases was increasing rapidly. Shortly after Ontario implemented each state of emergency, the number of new daily cases started to level off and then steadily decline. This is illustrated in the graph below with data from PHO showing the number of daily new cases from September 1, 2021 to June 17, 2021:



57. The number of daily new hospitalizations followed a similar trend. This is illustrated in the graph below with data from PHO showing the number of daily new hospitalizations from September 1, 2021 to June 17, 2021:



58. In their update to the public on May 20, 2021, the Ontario COVID-19 Science Table stated that "control of the pandemic is improving due to current public health measures." Among other things, the Science Table noted that the percentage of individuals testing positive for COVID-19 decreased following the implementation of the province-wide lockdowns and provincial emergency brake.

59. In short, many key public health indicators showed signs of significant improvement following the implementation of Ontario's strictest public health measures. While there are many factors that contribute to the transmission of COVID-19, this data suggests that Ontario's public health measures decreased the spread of COVID-19 across the province, reduced the overall strain on the healthcare system, and likely saved lives.

IV. Public Health Considerations That Informed Ontario's COVID-19 Policy Response

60. As noted above, as Associate Chief Medical Officer of Health, my responsibilities include monitoring the spread of COVID-19 and advising the Ontario government on its policy response to the pandemic. In that role, I continuously review and assess information related to COVID-19, including published peer-reviewed literature, "scientific grey literature" (i.e. literature published outside of traditional peer-reviewed publishing channels), and publications from PHO. That information informs the advice that I provide, along with others in the office of the Chief Medical Officer of Health, to the Ontario government. I review information and provide advice related to COVID-19 as part of the ordinary exercise of my knowledge, training and experience as Associate Chief Medical Officer of Health.

61. Below are some of the public health considerations that inform Ontario's policy response to the pandemic. These considerations are not exhaustive and no single factor is determinative. It should also be noted that the state of the pandemic is constantly changing and Ontario's policy response must adapt to those changing circumstances. When determining which health protection measures should be implemented to mitigate the spread of the virus, Ontario attempted to use the best information available at the time about the transmissibility of COVID-19, which was also subject to change as research about the virus is being updated regularly.

(i) Methods of COVID-19 Transmission

62. The primary method of transmission of COVID-19 is through direct contact with respiratory droplets from an infected person, which have the potential to be propelled various distances when that person coughs, sneezes, sings, shouts or talks. Transmission occurs predominantly through close contact (2 metres or less) with an infected individual, but transmission over longer distances (more than 2 metres) is possible, although less common. Attached as **Exhibit "BB"** is a document dated December 1, 2020, from PHO entitled "COVID-19 Routes of Transmission," which summarizes some of the evidence related to COVID-19 transmission.

63. Transmission is more likely when people are in close physical proximity with an infected person over a prolonged period of time. The risk of transmission is especially high in settings with poor ventilation or where there is recirculation of unfiltered air, which may allow droplets (or, in some cases, smaller particles known as "aerosols") to travel further distances. For example, there is evidence of high rates of transmission in household settings, where individuals are in close proximity in enclosed areas and physical distancing is not feasible. There is also evidence that indoor settings have a higher risk of transmission relative to outdoor settings, although there remains a risk of transmission when people gather outdoors.

64. Because COVID-19 is spread primarily through close contact with an infected individual, large gatherings, whether indoors or outdoors, present a risk of COVID-19 transmission. The larger the gathering, the greater the likelihood that there will be individuals in that gathering who have COVID-19 and will transmit the virus to others. If individuals in a gathering become infected, they will often transmit the virus to other members of their households. As a result, gatherings of

people from different households present an especially high risk of widespread transmission throughout the population.

65. Certain behaviours may increase the risk of COVID-19 transmission. For example, activities such as singing, shouting, or loud talking can result in more forceful exhalation of droplets (or, in some cases, aerosols), which increases the likelihood of transmitting the virus to others in close proximity and may also increase the distance that droplets or aerosols travel. Attached as **Exhibit "CC"** is a document dated May 21, 2021, from PHO entitled "COVID-19 Transmission Through Large Respiratory Droplets and Aerosols."

66. COVID-19 can be transmitted by people who are pre-symptomatic (i.e. have not yet developed symptoms) or asymptomatic (i.e. never developed symptoms). Some studies have shown that transmission can occur as early as six days before the onset of symptoms, or possibly earlier. As a result, screening for symptoms is insufficient to prevent the spread of COVID-19 when individuals gather in groups, particularly when the level of COVID-19 in the general population is high. Attached as **Exhibit "DD"** is a document dated May 22, 2020, from PHO entitled "Asymptomatic Infection and Asymptomatic Transmission."

(ii) Masks and Physical Distancing

67. There are several measures that can help reduce, but not eliminate, the risk of COVID-19 transmission. One of those measures is mask wearing. Masks have two potential functions. First, they can be used as personal protective equipment ("PPE") to protect the wearer from being exposed to droplets expelled by others who have been infected with COVID-19. Second, they can be used as "source control" to protect others from the wearer by reducing the degree to which a person who is infected with COVID-19 expels droplets.

68. There is evidence that the use of non-medical masks can be an effective form of source control when worn by persons shedding the virus (i.e. it protects others from a mask wearer with COVID-19). A literature review conducted by PHO found that "[m]andatory public mask policies have been associated with a decrease in new COVID-19 cases compared to regions without such policies." Attached as **Exhibit "EE"** is a document dated September 14, 2020, from PHO entitled "Wearing Masks in Public and COVID-19."

69. However, the same review by PHO found that the use of masks to protect the wearer (i.e. as PPE) is "unlikely to be effective in non-healthcare settings." As a result, if one or more infected individuals within a gathering do not wear a mask (or do not wear a mask consistently), the fact that others within the gathering are wearing masks is unlikely to provide sufficient protection against transmission. The efficacy of mask mandates is, therefore, highly dependent on the degree to which participants strictly and uniformly adhere to those mandates, especially in large gatherings or settings with poor ventilation.

70. There is an extremely high degree of variability in the efficacy of non-medical masks in public settings, depending on the materials used and whether the mask is the appropriate fit for the wearer. For example, one review of 42 studies on the effectiveness of non-medical masks in reducing COVID-19 transmission found that the filtration efficiency of non-medical masks (with variable designs and fabrics) ranged from less than 10% to more than 95%. Attached as **Exhibit "FF"** is a document dated February 2, 2021 from PHO entitled "Review of 'Rapid review on the characteristics of effective non-medical face masks in reducing the risk of SARS-CoV-2 transmission.'"

71. Guidance from the World Health Organization ("**WHO**") states that masks should be used as "part of a comprehensive package of prevention and control measures" to limit the spread

of COVID-19. However, that guidance also notes that "the use of a mask alone, even when correctly used…is insufficient to provide an adequate level of protection for an uninfected individual or prevent onward transmission from an infected individual (source control)." Attached as **Exhibit "GG"** is document dated December 1, 2020, from the WHO entitled "Mask use in the context of COVID-19."

72. Another measure that can help reduce, but not eliminate, the risk of COVID-19 transmission is physical distancing. As noted above, respiratory droplets from an infected person have the potential to be propelled various distances when that person coughs, sneezes, sings, shouts or talks. While transmission is most likely to occur through close contact of 2 metres or less, there is evidence that transmission over longer distances can occur, especially in areas with poor ventilation. Behaviours such as singing or loud talking have been shown to increase the distance that droplets can spread. Some studies have suggested that droplets can travel as much as 4 to 8 metres under favourable conditions (see **Exhibit "BB"**).

73. Similar to masks, physical distancing is one part of a comprehensive package of public health measures that can help reduce the transmission of COVID-19 but is insufficient on its own to prevent transmission of COVID-19. Furthermore, the efficacy of physical distancing depends on the degree to which individuals strictly adhere to physical distancing requirements of at least 2 metres. In practice, there will be some circumstances where physical distancing will be unlikely or impractical, such as within households.

(iii) Community Prevalence and Burden on the Healthcare System

74. The risk of COVID-19 transmission in any setting or gathering is related to the baseline level of COVID-19 in the community. The higher the number of COVID-19 cases in the population, the more likely it is that people who participate in a gathering will have COVID-19

and pass it on to others. While some types of gatherings may pose a relatively low risk of transmission when the level of COVID-19 in the population is low, those same gatherings may pose a higher risk of transmission when the level of COVID-19 in the population is high.

75. Ontario's policy response to COVID-19 was also informed by the burdens that the pandemic placed on the healthcare system. Several times during the pandemic, the spread of COVID-19 caused hospitalizations and ICU occupancy to increase significantly. This placed a substantial burden on the healthcare system, as Ontario has limited capacity to treat seriously ill patients who require hospitalization or intensive care. The increase in ICU patients was particularly concerning because it not only threatened the ability of the healthcare system to deal with COVID-19 patients, it also compromised the ability of the healthcare system to care for regular (i.e. non-COVID-19) patients. The diversion of healthcare resources to serve seriously ill patients with COVID-19 also creates a backlog of surgical and other medical treatments for other medical problems.

76. When the burdens on the healthcare system are high, even small increases in transmission within the population can have a significant negative impact on the healthcare system and potentially impact patient care. For example, in April 2021, ICU occupancy in some regions in Ontario was over 86%. At that time, there was a risk that ICU capacity would be stretched beyond its limits, even with small increases in the number of critically ill patients. Within that context, activities that pose a relatively low risk of transmission could significantly increase the burden on an already strained healthcare system.

(iv) Variants of Concern

77. The risk of COVID-19 transmission also depends on the degree of transmissibility of the virus, which has evolved over time as new variants have emerged. Several VOCs have been

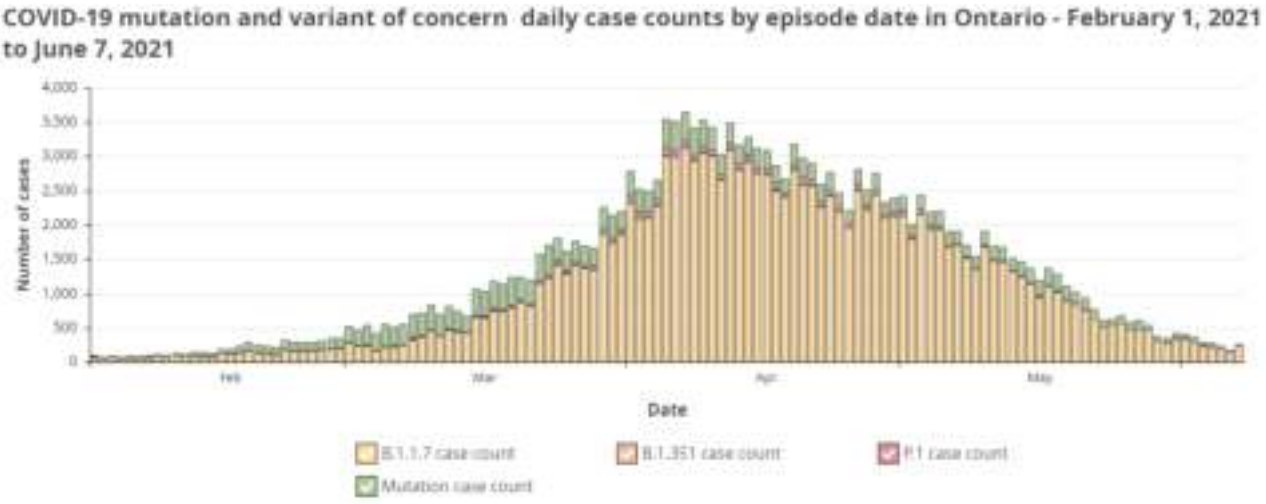
identified that are associated with factors such as increased transmissibility, detrimental change in COVID-19 epidemiology, increased virulence or change in clinical disease presentation, and decreased effectiveness of public health and social measures.

78. There are four VOCs that are particularly concerning in Ontario, namely:

- the B.1.1.7 (Alpha) variant, which was first detected in the United Kingdom;
- the B.1.351 (Beta) variant, which was first detected in South Africa;
- the P.1 (Gamma) variant, which was first detected in Brazil; and
- the B.1.617 (Delta) variant, which was first detected in India.

79. All four of these VOCs are associated with increased transmissibility of COVID-19. The Alpha, Beta and Gamma variants are each estimated to be at least 50% more transmissible than the original COVID-19 virus. Information about the Delta variant is still evolving, but evidence suggests that it is considerably more transmissible than non-variant strains of COVID-19. All four VOCs have been detected in Ontario. Attached as **Exhibit "HH"** is a publication by PHO entitled "Comparing SARS-CoV-2 Variants of Concern (VOCs) as of May 31, 2021." Attached as **Exhibit "II"** is a publication by PHO dated June 16, 2021, entitled "COVID-19 B.1.617 Variant of Concern – What We Know So Far."

80. In February and March 2021, the proportion of cases involving VOCs increased substantially. By April 2021, the Alpha variant had become the dominant strain in Ontario and over 70% of reported cases in the province tested positive for one of the VOCs. Attached as **Exhibit "JJ"** is a graph summarizing the percentage of COVID-19 associated with a VOC from March 31, 2021, to April 13, 2021. Below is a graph from PHO showing the progression of COVID-19 cases with a VOC from February 1, 2021 to June 7, 2021 (excluding the Delta variant):



81. In May and June 2021, there was an increase in the number of cases in Ontario testing positive for the Delta variant. As of June 22, 2021, 975 cases of the Delta variant had been confirmed in Ontario. Attached as **Exhibit "KK"** is the daily epidemiological summary from PHO dated July 3, 2021, which contains data regarding VOCs, including the Delta variant, from January 15, 2020 to July 3, 2021.

V. The Risks of COVID-19 Transmission at Religious Gatherings

82. In light of the factors described above, religious services and gatherings pose a significant risk for the spread of COVID-19. They typically involve large gatherings of people from different households who spend prolonged periods of time (often more than an hour) in the same physical space. That is precisely the scenario that has been shown to be associated with a high risk COVID-19 transmission. That risk is especially high if physical distancing is not strictly observed, if the services are held indoors or in poorly ventilated areas, or if masks are not worn (or not worn consistently or correctly).

83. Religious services are often associated with behaviours that can increase the spread of COVID-19. For example, many religious services involve singing, chanting or praying out loud,

which can increase the spread of droplets that transmit the virus. Religious services are also typically gatherings of families and friends in the same community who know each other well and will be tempted to greet or socialize with each other in violation of physical distancing requirements. While places of worship may take measures to promote physical distancing, in practice good intentions are often outweighed by human nature.

84. The risk of transmission at a religious gathering is not confined to those who attend those gatherings. If someone is infected with COVID-19 at a religious service, it is very likely that he or she will transmit the virus to other members of his or her household who, in turn, may transmit COVID-19 to others in the community.

85. The risk of transmission at religious gatherings increases significantly when the prevalence of COVID-19 in the community is high. The higher the number of COVID-19 cases in the general population, the more likely it is that people who participate in a religious gathering will have COVID-19 and pass it on to others. In addition, when COVID-19 cases in the general population are high, there is a greater burden on the healthcare system. When that occurs, even small amounts of transmission at religious gatherings can have a significant impact on the overall spread of the virus across the province, resulting in an even greater strain on the healthcare system and potentially impacting patient care.

86. Masks and physical distancing can help reduce the risk of COVID-19 transmission but are insufficient to stop the spread of the virus, particularly when the prevalence of COVID-19 in the population is high. As noted above, masks can be highly variable in their effectiveness in non-healthcare settings and their effectiveness decreases if they are ill-fitting or worn inconsistently. In addition, physical distancing of at least 2 metres decreases the likelihood of COVID-19 transmission, but there is evidence that droplets (or in some cases aerosols) can travel farther

distances under some conditions, although transmission at distances of more than 2 metres is less common. Similarly, holding gatherings outdoors can reduce the risk of transmission of the virus, but outdoor transmission can still occur, especially in large gatherings with inconsistent adherence to mask or physical distancing requirements.

VI. The Public Health Measures for Religious Gatherings

87. In order to limit the spread of COVID-19, Ontario implemented several public health restrictions for religious gatherings over the various phases of the pandemic. The objective of those restrictions was to reduce transmission by limiting the number of people who would gather together in close contact and to require participants to take certain precautions, such as mask wearing and physical distancing. The limits that applied to religious gatherings were part of a broader set of measures that applied to a wide variety of businesses, organizations and events throughout the province.

88. The public health measures Ontario has imposed at each stage of the pandemic have been informed by several key indicators, such as weekly incidence of COVID-19, the test positivity rate, the effective reproduction number (Rt), and evidence of recent outbreaks. Where feasible, public health measures have been tailored to the circumstances in each region of the province. During some phases of the pandemic, however, the rapid spread of COVID-19 or the need to discourage travel between different areas of the province required Ontario to implement restrictions that applied across the entire province.

89. I understand that the applicants in these proceedings are challenging the restrictions that applied to religious services in three different public health units ("**PHUs**"): the Niagara PHU, the Southwestern PHU, and the Region of Waterloo PHU. I have summarized below the restrictions that applied to religious gatherings in those PHUs from September 2020 to June 2021.

90. The table below summarizes the capacity limits that applied to religious services, rites or ceremonies in the Niagara PHU:

Capacity Limits for Religious Services, Rite or Ceremonies in the Niagara PHU

Date	Outdoor Services	Indoor Services	Drive-in Services
July 22, 2020 to December 25, 2020	100 people.	30% of room capacity.	Drive-in services permitted without any capacity limit.
December 26, 2020 to February 28, 2021	10 people.	10 people.	Drive-in services permitted without any capacity limit.
March 1, 2021 to March 28 , 2021	100 people.	30% of room capacity.	Drive-in services permitted without any capacity limit.
March 29, 2021 to April 2, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	30% of room capacity.	Drive-in services permitted without any capacity limit.
April 3, 2021 to April 18, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity.	Drive-in services permitted without any capacity limit.
April 19, 2021 to June 10, 2021	10 people.	10 people.	Drive-in services permitted without any capacity limit.
June 11, 2021 to June 29, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity.	Drive-in services permitted without any capacity limit.
June 30, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	25% of room capacity.	Drive-in services permitted without any capacity limit.

91. The table below summarizes the capacity limits that applied to religious services, rites or ceremonies in the Southwestern PHU:

Capacity Limits for Religious Services, Rite or Ceremonies in the Southwestern PHU

Date	Outdoor Services	Indoor Services	Drive-in Services
July 13, 2020 to December 25, 2020	100 people.	30% of room capacity.	Drive-in services permitted without any capacity limit.
December 26, 2020 to February 15, 2021	10 people.	10 people.	Drive-in services permitted without any capacity limit.
February 16, 2021 to March 28, 2021	100 people.	30% of room capacity.	Drive-in services permitted without any capacity limit.
March 29, 2021 to April 2, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	30% of room capacity.	Drive-in services permitted without any capacity limit.
April 3, 2021 to April 18, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity.	Drive-in services permitted without any capacity limit.
April 19, 2021 to June 10, 2021	10 people.	10 people.	Drive-in services permitted without any capacity limit.
June 11, 2021 to June 29, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity.	Drive-in services permitted without any capacity limit.

Date	Outdoor Services	Indoor Services	Drive-in Services
June 30, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	25% of room capacity.	Drive-in services permitted without any capacity limit.

92. The table below summarizes the capacity limits that applied to religious services, rites or ceremonies in the Waterloo PHU:

Capacity Limits for Religious Services, Rite or Ceremonies in the Waterloo PHU

Date	Outdoor services	Indoor services	Drive-in services
July 17, 2020 to December 25, 2020	100 people.	30% of room capacity.	Drive-in services permitted without any capacity limit.
December 26, 2020 to February 15, 2021	10 people.	10 people.	Drive-in services permitted without any capacity limit.
February 16, 2021 to March 28 2021	100 people.	30% of room capacity.	Drive-in services permitted without any capacity limit.
March 29, 2021 to April 2, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	30% of room capacity.	Drive-in services permitted without any capacity limit.
April 3, 2021 to April 18, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity.	Drive-in services permitted without any capacity limit.
April 19, 2021 to June 10, 2021	10 people.	10 people.	Drive-in services permitted without any capacity limit.

Date	Outdoor services	Indoor services	Drive-in services
June 11, 2021 to June 29, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity.	Drive-in services permitted without any capacity limit.
June 30, 2021	No capacity limit, provided participants follow masking and physical distancing health guidance.	15% of room capacity (pursuant to the instructions discussed at para. 54).	Drive-in services permitted without any capacity limit.

93. The time periods with the lowest (or strictest) capacity limits corresponded to the time periods when the rate of COVID-19 transmission in the Ontario population and the burden on the Ontario healthcare system were at their highest levels. This is consistent with the principles discussed above regarding COVID-19 transmission, including that there are higher risks of COVID-19 transmission in a religious gathering when the baseline number of COVID-19 cases in the general population is higher.

94. Throughout most of the pandemic, the capacity limits for outdoor religious gatherings were higher (or less strict) than the capacity limits for indoor religious gatherings. This is consistent with the evidence that the risk of COVID-19 transmission is generally higher indoors compared to outdoors. However, during some periods when the rate of COVID-19 transmission and the burden on the healthcare system were at their highest, capacity limits for both indoor and outdoor religious gatherings were the same. During those periods, the rate of transmission was so high that outdoor gatherings that would otherwise have posed a relatively small risk of transmission could still have had a significant impact on the overall spread of the virus across the province. The higher the number of COVID-19 cases in the population, the more likely it is that people who participate in a religious gathering will have COVID-19 and pass it on to others. While each individual gathering

may result in a relatively small risk of additional cases, the cumulative impact of many such gatherings could result in a significant increase in transmission across the province.

95. In addition, during the highest risk periods, Ontario's ICUs were approaching full capacity and there was a serious concern that, if the number of new cases and hospitalizations continued to rise, it could overburden the healthcare system and significantly jeopardize patient care. During those time periods of highest risk, it was extremely important to control the spread of COVID-19 at both indoor and outdoor gatherings.

96. It should be noted that the public health measures imposed on indoor and outdoor religious gatherings, even during the highest risk periods, were almost always less strict than the public health measures imposed on other types of gatherings. For example, during the third state of emergency, indoor or outdoor gatherings (other than religious gatherings) were only permitted with members of the same household or one other person from outside that household who lives alone or who is a caregiver for any member of the household. At the same time, religious gatherings were permitted with up to 10 people, which could include members of different households. To take another example, when Ontario moved into Step 1 of the Roadmap, outdoor social gatherings or organized public events (other than religious services) were subject to a capacity limit of 10 people, but outdoor religious services had no capacity limit, provided the participants complied with public health and physical distancing guidelines.

97. There are several reasons why Ontario imposed slightly different measures for religious gatherings. Among other things, the higher capacity limits allowed a small number of people who may not be in the same household to produce and disseminate virtual religious services to a wider community. A capacity limit of 10 people permits a few members of the public (such as readers, cantors, etc.) to assist officiants in conducting the larger online or drive-in services that remained

permitted. Ontario recognizes that religious communities are often a source of support, comfort and guidance for the communities they serve. Religious leaders can provide pastoral and spiritual support during public health emergencies and other health challenges. The public health measures for religious gatherings attempted to allow religious services to continue so that members of religious communities could access the benefits of those services, but with strict capacity limits that mitigate the spread of COVID-19.

VII. Public Health Measures in Other Settings

98. I understand that some of the applicants in these proceedings are arguing that the public health measures that applied to religious gatherings at various stages of the pandemic were not necessary or justified. In support of that argument, I understand that the applicants note that some public health measures that applied to non-religious gatherings or settings, such as essential retail stores, were (in their view) not as strict as the public health measures placed on religious gatherings at certain points during the pandemic.

99. It should be noted that the various restrictions imposed by the Province to reduce the spread of COVID-19 at different times, in different regions of the province, and in different sectors are based on the unique circumstances of each region and sector and the changing nature of the COVID-19 pandemic. Comparing the restrictions that apply in one circumstance to those that apply in another is not a useful or appropriate exercise without taking into account the full context of each circumstance. Every health protection measure implemented by the Province was assessed on its own merits and the factors that apply in determining whether a measure is appropriate in one circumstance may not apply, or may not apply to the same degree, in another.

100. It is important to keep those principles in mind when assessing the public health measures that applied to religious gatherings at various stages of the pandemic. As noted above, religious

gatherings are associated with a combination of risk factors, which may not apply, or may not apply to the same degree, in other settings.

101. Having said that, there are several reasons why Ontario imposed different public health measures on essential retail businesses compared to religious gatherings. Ontario imposed different limits on those retail businesses not because religious worship is any less essential than retail activities, but because religious gatherings typically have characteristics that make them more likely to spread COVID-19 than transient encounters in a retail setting.

102. The behaviour of persons in religious spaces is different than the behaviour of persons in retail spaces. First, people spend, on average, more time at religious gatherings compared to retail settings. It is not uncommon for a person to "run in" to retail stores to quickly purchase a number of small items. In contrast, religious gatherings are often an extended length and typically run for more than an hour, and sometimes for two hours or more. In addition, large groups of people tend to arrive and depart religious services at the same time, which increases crowding, in contrast to retail stores where people typically arrive and depart at many different times.

103. Second, the nature of human interaction in a retail setting tends to be different than human interaction at religious gatherings. Interactions with people outside of a person's household in a retail store are usually brief (e.g. passing someone in a store aisle). In contrast, at religious gatherings, there is often prolonged exposure to the same people sitting together, which presents a greater danger for the spread of the virus, especially if social distancing rules are not followed, the indoor space is not well ventilated, or where face coverings are not worn correctly. Another example is that, in a religious space, people often pray out loud or sing (which is not a concern in retail settings), which increases the risk of transmission.

104. Third, unlike in religious gatherings, there is typically no sense of community in retail settings, such that groups of people would want to greet each other in violation of physical distancing rules. While well-intentioned people at religious gatherings may attempt to physically distance from family and friends, good intentions are often outweighed by human nature. The conflict between the desire to warmly greet friends and family and diligently following physical distancing rules is less of a concern in retail stores.

AFFIRMED by video conference by David McKeown of [redacted], before me at the City of Toronto on the 5th day of July, 2021, in accordance with O. Reg. 431/20, Administer the Oath or Declaration Remotely.

NEWS RELEASE

Ontario Releases COVID-19 Response Framework to Help Keep the Province Safe and Open

Government Provides Additional Details on $300 Million to Support Eligible Businesses

November 3, 2020
Office of the Premier

TORONTO — In consultation with the Chief Medical Officer of Health and other health experts, the Ontario government has developed the *Keeping Ontario Safe and Open Framework*. It ensures that public health measures are targeted, incremental and responsive to help limit the spread of COVID-19, while keeping schools and businesses open, maintaining health system capacity and protecting vulnerable people, including those in long-term care.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Rod Phillips, Minister of Finance, Peter Bethlenfalvy, President of the Treasury Board, and Dr. David Williams, Chief Medical Officer of Health.

"It's clear COVID-19 will be with us for a while, which is why we are putting in place a framework that will protect the health and safety of individuals and families, while avoiding broader closures across the province," said Premier Ford. "This framework, developed in consultation with our health experts, will serve as an early warning system allowing us to scale up and scale back public health restrictions on a regional or community basis in response to surges and waves of COVID-19. By introducing public health measures sooner, we can keep this deadly virus at bay, bend the curve and reclaim a little more of our normal lives."

The framework takes a gradual approach that includes introducing preventative measures earlier to help avoid broader closures and allow for additional public health and workplace safety measures to be introduced or removed incrementally. It categorizes public health unit regions into five levels: Green-Prevent, Yellow-Protect, Orange-Restrict, Red-Control, and Lockdown being a measure of last and urgent resort. Each level outlines the types of public health and workplace safety measures for businesses and organizations. These include targeted measures for specific sectors, institutions and other settings.

"The health and wellbeing of Ontarians is our number one priority. This framework, informed by public health experts, data and the experiences of other jurisdictions, is focused on introducing less invasive measures earlier to stop the spread of COVID-19," said Minister Elliott. "We are committed to being transparent with Ontarians, businesses and local communities as we work together to keep Ontarians safe, while keeping our economy open."

"This framework is critical to ensuring that public health measures are able to help slow the spread of the virus, while also supporting mental health and other social determinants of health," said Dr. Williams. "The framework operates like a dimmer switch, enabling measures and restrictions to be increased and give individuals and families the information they need to adjust their activities and interactions based on local epidemiological data."

As the province continues to expand access to real-time data, enhancements are also being made to Ontario.ca/coronavirus, Ontario's one-stop shop for information on COVID-19. Information about the spread of the virus, and public health and health system capacity will now be available on the website. This includes local cases by public health unit regions, the total number of cases, resolved cases, deaths, and tests completed and how many are positive. The province will continue to add data sets as they become available, such as sources of outbreaks as a subset of overall cases. This information will better help businesses, organizations and local communities access key information to prepare in advance for any changes in their region.

"You deserve to have access to the same information that we have, and that's why our government is enhancing online data and data visualization," said Minister Bethlenfalvy. "Greater transparency means that the people of Ontario have reliable access to the information they need to protect their health, and for businesses to reopen and operate safely. This is another way we're using technology and pursuing innovation to put the people at the centre of government and move Ontario onwards."

To provide the utmost transparency, each public health unit will be classified according to current framework indicators. Proposed classifications based on data for the week of October 26, 2020 can be found below. These will be confirmed by the province on Friday, November 6, 2020 and become effective on Saturday, November 7, 2020 at 12:01 a.m. Final decisions on moving public health unit regions into the framework will be made by the government based on updated data and in consultation with the Chief Medical Officer of Health, local medical officers of health and other health experts, and will be reviewed weekly.

Going forward, the government will continually assess the impact of public health measures applied to public health unit regions for 28 days, or two COVID-19 incubation periods.

Supporting Businesses Affected by COVID-19 Public Health Measures

The Ontario government is making $300 million available to businesses required to close or significantly restrict services in areas subject to modified Stage 2 public health restrictions (Ottawa, Peel, Toronto, and York Region) or, going forward, in areas categorized as Control or Lockdown.

Rebates will cover the period of time that businesses are required to temporarily close or significantly restrict services as a result of being located in areas subject to the targeted modified Stage 2 public health restrictions or, going forward, in areas categorized as Control or Lockdown.

Beginning November 16, 2020, eligible businesses will be able to apply for temporary property tax and energy cost rebates directly to the province through a single, online application portal. Many businesses should expect to receive their rebate payments within a few weeks of finalizing and submitting their completed application. Eligible businesses include restaurants, bars, gyms and cinemas.

"On Thursday, I'll introduce Ontario's 2020 Budget, the next phase of Ontario's Action Plan," said Minister Phillips. "It is a plan that will have three pillars. As we announced yesterday, the first is protect. The second pillar is support, because we know COVID-19 has brought severe challenges and economic difficulties to families and employers. Supporting businesses affected by necessary public health restrictions in regions experiencing a greater risk from COVID-19 is one way we are helping employers manage during these difficult times."

Through Ontario's Property Tax and Energy Cost Rebates program, the government is building on its efforts to ensure eligible businesses receive the financial help they need as a result of targeted provincial public health restrictions.

Public Health Unit Region Classifications

As of November 7, 2020, the province will transition public health unit regions to the new framework. The following proposed classifications for public health unit regions are based on data for the week of October 26, 2020. Updated data will be used for final review by the Chief Medical Officer of Health and approval by Cabinet on Friday, November 6, 2020.

Lockdown:

- No public health unit regions

Red-Control:

- No public health unit regions

Orange-Restrict:

- Eastern Ontario Health Unit;
- Ottawa Public Health;
- Peel Public Health;
- Toronto Public Health (may be delayed in entering Orange-Restrict level until November 14, 2020); and
- York Region Public Health.

Yellow-Protect:

- Brant County Health Unit;
- City of Hamilton Public Health Services;
- Durham Region Health Department; and
- Halton Region Public Health.

Green-Prevent:

- Algoma Public Health;
- Chatham-Kent Public Health;
- Grey Bruce Health Unit;
- Kingston, Frontenac and Lennox & Addington Public Health;
- Haliburton, Kawartha, Pine Ridge District Health Unit;
- Haldimand-Norfolk Health Unit;
- Hastings Prince Edward Public Health;
- Huron Perth Public Health;
- Lambton Public Health;
- Leeds, Grenville & Lanark District Health Unit;
- Middlesex-London Health Unit;
- Niagara Region Public Health;
- North Bay Parry Sound District;
- Northwestern Health Unit;
- Peterborough Public Health;
- Porcupine Health Unit;
- Public Health Sudbury & Districts;
- Region of Waterloo Public Health and Emergency Services;
- Renfrew County and District Health Unit;
- Simcoe Muskoka District Health Unit;
- Southwestern Public Health;
- Thunder Bay District Health Unit;
- Timiskaming Health Unit;
- Wellington-Dufferin-Guelph Public Health; and
- Windsor-Essex County Health Unit.

Quick Facts

- The Ontario government has developed a $2.8 billion COVID-19 fall preparedness plan, *Keeping Ontarians Safe: Preparing for Future Waves of COVID-19*, to ensure the province's health care, long-term care and education systems are prepared for the immediate challenges of the fall, including a second wave of COVID-19 and the flu season.
- If you are concerned you were exposed to COVID-19 or have symptoms, take the online COVID-19 self assessment.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert app. Visit Ontario.ca/covidtest to find the nearest testing location.
- Types of businesses that are eligible for support include restaurants and bars, bingo halls, gaming establishments, casinos, conference centres and convention centres, gyms, facilities for indoor sports and recreational fitness activities, community centres and multi-purpose facilities, museums, performing arts and cinemas and personal care services (with exception of oxygen bars) that were required to close or are subject to significant restrictions under modified Stage 2.
- Businesses that are not eligible are those that were already required to close prior to the introduction of modified Stage 2 public health restrictions, those that were not required to close or restrict services due to modified Stage 2 public health restrictions, and those who do not pay property taxes or energy costs.

Additional Resources

- Ontario Moving Additional Region to Modified Stage 2
- Ontario Implementing Additional Public Health Measures in Toronto, Ottawa and Peel Region

NEWS RELEASE

Ontario Moves Public Health Unit Regions into COVID-19 Response Framework to Keep Ontario Safe and Open

New approach introduces preventative measures earlier to limit transmission of COVID-19 and avoid broader closures

November 06, 2020
Health

TORONTO — In consultation with the Chief Medical Officer of Health, local medical officers of health, and other health experts, the province intends to move Ontario's public health unit regions to the *Keeping Ontario Safe and Open Framework*. The framework categorizes public health regions into five levels: Green-Prevent, Yellow-Protect, Orange-Restrict, Red-Control, and Lockdown being a measure of last and urgent resort.

"The framework lays out a proactive and graduated response to be applied based on the local situation in each region," said Dr. David Williams, Chief Medical Officer of Health. "By working with the medical officers of health and local authorities on the realities and situations of COVID-19, we want to continue to help protect people's health and wellbeing. We are adapting the public health measures to be as targeted and efficient as possible to stop the spread of the virus, while managing any outbreaks as quickly as possible."

At the request of the local medical officer of health, and with the support of Ontario's Chief Medical Officer of Health, Toronto Public Health would remain in a modified Stage 2 until November 14, 2020.

As of Saturday, November 7, 2020 at 12:01 a.m., public health unit regions would be moved to the following levels:

Lockdown:

- No public health unit regions.

Red-Control:

- Peel Regional Health Unit.

Orange-Restrict:

- Ottawa Public Health; and
- York Region Public Health.

Yellow-Protect:

- Brant County Health Unit;
- City of Hamilton Public Health Services;
- Durham Region Health Department;
- Eastern Ontario Health Unit;
- Haldimand-Norfolk Health Unit;
- Halton Region Public Health;
- Niagara Region Public Health;
- Region of Waterloo Public Health and Emergency Services;
- Simcoe Muskoka District Health Unit; and
- Wellington-Dufferin-Guelph Public Health.

Green-Prevent:

- Algoma Public Health;
- Chatham-Kent Public Health;
- Grey Bruce Health Unit;

- Kingston, Frontenac and Lennox & Addington Public Health;
- Haliburton, Kawartha, Pine Ridge District Health Unit;
- Hastings Prince Edward Public Health;
- Huron Perth Public Health;
- Lambton Public Health;
- Leeds, Grenville & Lanark District Health Unit;
- Middlesex-London Health Unit;
- North Bay Parry Sound District;
- Northwestern Health Unit;
- Peterborough Public Health;
- Porcupine Health Unit;
- Public Health Sudbury & Districts;
- Renfrew County and District Health Unit;
- Southwestern Public Health;
- Thunder Bay District Health Unit;
- Timiskaming Health Unit; and
- Windsor-Essex County Health Unit.

Public health measures required for each level can be found in the *Keeping Ontario Safe and Open Framework*.

For long-term care homes, visitor restrictions remain in effect for the following public health unit regions: Ottawa, Peel, Toronto, and York Region.

"COVID-19 will be with us for awhile, which is why we have put in place a framework that introduces more public health measures sooner to limit transmission of COVID-19 in our communities while avoiding broader closures," said Christine Elliott, Deputy Premier and Minister of Health. "We are committed to being transparent with Ontarians, businesses and local communities as we work together to keep Ontarians safe, while keeping our economy open."

The *Keeping Ontario Safe and Open Framework* takes a comprehensive, whole of government approach by introducing preventative measures earlier to help avoid broader closures and allow for additional public health and workplace safety measures to be introduced or removed gradually. It ensures that public health measures are targeted, incremental and responsive to help limit the spread of COVID-19, while keeping schools and businesses open, maintaining health system capacity and protecting vulnerable people, including those in long-term care.

Trends in public health data will be reviewed weekly. At the same time, the government will continually assess the impact of public health measures for 28 days, or two COVID-19 incubation periods to determine if public health units should stay where they are or be moved into a different level.

The Ontario government is making $300 million available to businesses required to close or significantly restrict services in areas subject to modified Stage 2 public health restrictions, or, going forward, in areas categorized as Control or Lockdown. As a result, businesses in these areas will be able to apply for temporary property tax and energy cost rebates directly to the province through a single, online application portal.

As the province continues to expand access to real-time data, enhancements are also being made to Ontario.ca/coronavirus, Ontario's one-stop shop for information on COVID-19. Information about the spread of the virus, and public health and health system capacity will now be available on the website. This includes local cases by public health unit regions, the total number of cases, resolved cases, deaths, and tests completed and how many are positive. This information will better help businesses, organizations and local communities access key information to prepare in advance for any changes in their region.

Quick Facts

- The framework categorizes public health unit regions into five levels: Green–Prevent, Yellow–Protect, Orange–Restrict, Red–Control, and Lockdown. Each level outlines the types of public health and workplace safety measures for businesses and organizations. These include targeted measures for specific sectors, institutions and other settings.
- Municipalities and local medical officers of health may have additional restrictions or targeted requirements in their region, on top of the public health measures required at their specific level.
- The Ontario government has developed a $2.8 billion COVID-19 fall preparedness plan, *Keeping Ontarians Safe: Preparing for Future Waves of COVID-19*, to ensure the province's health care, long-term care and education systems are prepared for the immediate challenges of the fall, including a second wave of COVID-19 and the flu season.

- On November 5, 2020, the Ontario government released the 2020 Budget, *Ontario's Action Plan: Protect, Support, Recover*, which outlines how the province is protecting people during the COVID-19 pandemic by investing $15.2 billion in health care.
- If you are concerned you were exposed to COVID-19 or have symptoms, take the online COVID-19 self assessment.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert app. Visit Ontario.ca/covidtest to find the nearest testing location.
- To stay safe, you can download the COVID Alert App free from the Apple and Google Play app stores.

NEWS RELEASE

Ontario Updating COVID-19 Response Framework to Help Stop the Spread of COVID-19

Modelling Shows New Thresholds Needed to Bend the Curve and Keep People Safe

November 13, 2020
Office of the Premier

TORONTO — In consultation with the Chief Medical Officer of Health and the Public Health Measures Table, the Ontario government is taking immediate action to respond to the rapid increase in COVID-19 cases and is updating the *Keeping Ontario Safe and Open Framework*, by lowering the thresholds for each level in the framework. These necessary updates will help limit the spread of COVID-19 while keeping schools open, maintaining health system capacity, protecting the province's most vulnerable, and avoiding broader lockdowns.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, and Dr. David Williams, Chief Medical Officer of Health.

"Our number one priority right now is getting the numbers down and keeping people safe. That's why, on the recommendation of the Chief Medical Officer of Health, we're updating the framework with new thresholds so we can slow the spread of this virus," said Premier Ford. "These adjustments are necessary to respond to the latest evidence we're seeing and we are prepared to make further adjustments as the health experts continue to review the current public health restrictions. We must do whatever it takes to stop our hospitals from being overwhelmed and protect our most vulnerable."

The latest modelling shows that if the number of new cases continues to grow at its current rate, the province could register up to 6,500 new cases per day by mid-December. Within the next two weeks the province will likely exceed its intensive care threshold of 150 beds, under any potential scenario.

The framework changes are in response to the current data and trends, and will lower the threshold for each of the five levels for: weekly incidence rates, positivity rate, effective reproductive number (Rt), outbreak trends and the level of community transmission. Based on these new thresholds, the following public health unit regions would be moved to the following levels in the framework:

- Red-Control:
  - Hamilton Public Health Services
  - Halton Region Public Health
  - Toronto Public Health
  - York Region Public Health

- Orange-Restrict:
  - Brant County Health Unit
  - Durham Region Health Department
  - Eastern Ontario Health Unit
  - Niagara Region Public Health
  - Wellington-Dufferin-Guelph Public Health
  - Region of Waterloo Public Health

- Yellow-Protect:
  - Huron Perth Public Health
  - Middlesex-London Health Unit
  - Public Health Sudbury & Districts
  - Southwestern Public Health
  - Windsor-Essex County Health Unit

Please visit Ontario.ca/COVID19 for the full list of public health region classifications that will come into effect as of Monday, November 16, 2020 at 12:01 a.m. Toronto Public Health will move into the framework on Saturday, November 14, 2020 at 12:01 a.m.

For long-term care homes, visitor restrictions will apply to public health regions within the Orange-Restrict and Red-Control levels in the framework. This will go into effect on Monday, November 16, 2020 at 12:01 a.m.

"Over the last week we have seen an alarming shift in the trends of key public health indicators in regions across the province," said Minister Elliott. "The COVID-19 pandemic continues to evolve, and our government's response must evolve with it. These updates to the COVID-19 Framework will ensure that the necessary targeted measures are in place in hotspots to help stop the spread of the virus and keep our schools and businesses open. Protecting the health and well-being of Ontarians remains our top priority."

The framework takes a gradual approach that includes introducing preventative measures earlier to help avoid broader closures and allow for additional public health and workplace safety measures to be introduced or removed incrementally. It categorizes public health unit regions into five levels: Green-Prevent, Yellow-Protect, Orange-Restrict, Red-Control, and Lockdown being a measure of last and urgent resort.

Ontario's COVID-19 Response Framework has been designed to:

- Be responsive and flexible to latest data;
- Introduce preventative measures earlier to help limit the spread of COVID-19, while keeping schools open, supporting mental health, protecting our most vulnerable, and keeping businesses open where possible;
- Recognize that every community is different and provide the flexibility to allocate resources where they are needed most; and
- Support the ability for local officials to tailor restrictions in their communities based on regional circumstances. The framework serves as a baseline that municipalities and local medical officers of health can build on by imposing additional restrictions or targeted requirements in their region, on top of the public health and workplace safety measures required at their specific level.

"The latest modelling shows a concerning situation in our province. Worldwide we are seeing COVID-19 cases continue to rise, and Ontario is no exception," said Dr. Williams. "It remains critical that everyone continue to strictly follow public health advice to protect yourself and your community. We bent the curve during the first wave and, although it will be challenging, we can do so again through the collective actions of all Ontarians."

Assignments to the current levels would last for a minimum of 28 days or two-incubation periods, at which time the status of these public health unit regions will be reassessed on a weekly basis. However, movement to a more restrictive zone will be considered sooner if there are rapidly worsening trends.

Since the beginning of the outbreak, Ontarians have been playing their part to help bend the curve and stop the spread of the virus. Today more than ever, it is critical for everyone to follow public health advice and strictly comply to the restrictions applied in their regions, especially when connecting with others. The following recommendations apply to all public health unit regions in the province:

- Avoid social gatherings and limit close contacts to your household or the people you live with;
- Adhere to the restrictions in your region on public and private gatherings;
- Maintain two metres of physical distancing from everyone else;
- Wear a face covering indoors and wear one outdoors if physical distancing may not be maintained or if wearing one is required;
- Wash your hands thoroughly and regularly;
- Stay home if you have COVID-19 symptoms, even if they are mild;
- Cover your cough;
- Get tested if you have symptoms compatible with COVID-19, or if you've been advised of exposure by your local public health unit or through the COVID Alert mobile app;
- Individuals and families from higher transmission regions should avoid travel to lower transmission regions, except for essential reasons; and
- Download the COVID Alert mobile app.

In addition, as the province continues to expand access to real-time data, enhancements have been made to Ontario.ca/coronavirus, Ontario's one-stop shop for information on COVID-19. Beginning today, users will now be able to view new, active, resolved, deceased, and total cases, by public health unit, on a map. In addition, the website will now provide Ontarians with an effective reproduction number, as well as enhanced long-term care data. The government will

continue to update the dashboard with relevant data to ensure as much transparency as possible. This information will better help businesses, organizations and local communities access key information to prepare in advance for any changes in their region.

Quick Facts

- Find out what level and which regional public measures are in place for your area.
- The Ontario government has developed a $2.8 billion COVID-19 fall preparedness plan, *Keeping Ontarians Safe: Preparing for Future Waves of COVID-19*, to ensure the province's health care, long-term care and education systems are prepared for the immediate challenges of the fall, including a second wave of COVID-19 and the flu season.
- The Ontario government is making $300 million available to businesses required to close or significantly restrict services in areas subject to modified Stage 2 (Red–Control level) public health restrictions, or, going forward, in Lockdown. As a result, businesses in these areas will be able to apply for temporary property tax and energy cost rebates directly to the province through a single, online application portal.
- If you are concerned you were exposed to COVID-19 or have symptoms, take the online COVID-19 self assessment.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert app. Visit Ontario.ca/covidtest to find the nearest testing location.
- To stay safe, you can download the COVID Alert App free from the Apple and Google Play app stores.

NEWS RELEASE

Ontario Taking Further Action to Stop the Spread of COVID-19

Province Also Doubling Financial Support for Businesses Affected by Additional Restrictions

November 20, 2020
Office of the Premier

TORONTO — In consultation with the Chief Medical Officer of Health, local medical officers of health, and other health experts, the province is moving certain public health unit regions to new levels in the *Keeping Ontario Safe and Open Framework*, which includes moving Toronto and Peel into Lockdown. These necessary measures are being taken to limit community transmission of COVID-19 in order to keep schools open, safeguard health system capacity, and protect the province's most vulnerable populations.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Rod Phillips, Minister of Finance, and Dr. David Williams, Chief Medical Officer of Health.

"With the numbers rising rapidly in certain regions, we have to make the tough, but necessary decisions now to protect our hospitals, long-term care and retirement homes, and every person in this province," said Premier Ford. "We cannot afford a province-wide lockdown, so we are taking preventative action today by moving Toronto and Peel into Lockdown level restrictions and other regions into higher levels of restrictions. We need to take decisive action to stop the spread of this deadly virus."

Over the past week, some regions under the Red-Control level have continued to see worsening trends in key indicators, despite having a range of public health measures and restrictions in place since early October. Based on the latest data, the government intends to move Peel Public Health and Toronto Public Health into Lockdown effective Monday, November 23, 2020 at 12:01 a.m. This action is being taken to help stop the spread of COVID-19, while prioritizing the continued opening of schools, child care centres and other key services to the fullest extent possible.

Measures under Lockdown include, but are not limited to:

- Schools, before and after school programs, and child care will remain open;
- Post-secondary schools open for virtual learning with some limited exceptions for training that can only be provided in-person, such as clinical training or training related to a trade;
- No indoor organized public events or social gatherings except with members of the same household. Individuals who live alone, including seniors, may consider having exclusive, close contact with another household;
- Outdoor organized public events or social gatherings limited to a maximum of 10 people;
- Wedding services, funeral services and religious services, rites or ceremonies where physical distancing can be maintained can have up to 10 people indoors or 10 people outdoors;
- Retail permitted to be open for curbside pick-up or delivery only, with certain exceptions such as for supermarkets, grocery stores, pharmacies, hardware stores, discount and big box retailers selling groceries, beer, wine and liquor stores, safety supply stores, and convenience stores, which will be allowed to operate at 50 per cent capacity;
- Restaurants, bars, and food and drink establishments will only be able to provide takeout, drive-through and delivery. Indoor and outdoor dining services are prohibited;
- Personal care services closed;
- Casinos, bingo halls and other gaming establishments closed; and
- Indoor sports and recreational facilities, including pools, closed with limited exceptions.

The Chief Medical Officer of Health and health experts will continue to provide advice to the government using criteria, including:

- Epidemiological indicators such as the number and rate of COVID-19 cases and test positivity;
- Health system capacity indicators including hospital and Intensive Care Unit capacity, access to ventilators and ongoing availability of personal protective equipment;

- Public health sector capacity, including the number of COVID-19 cases and contacts being reached by local public health officials within one day; and
- Ongoing testing of suspected COVID-19 cases, especially of vulnerable populations, to detect new outbreaks quickly.

"As public health indicators continue to worsen in regions across the province, particularly in hotspots like Peel and Toronto, it is clear that more needs to be done to limit community spread of COVID-19," said Minister Elliott. "As we have seen around the world, lockdowns are a difficult but necessary step to stop the spread, safeguard the key services we rely on and protect our health system capacity. With the recent positive news on the development of a vaccine, there is a real hope that we can defeat this deadly virus, but for now we all must continue to follow public health advice and strictly adhere to the restrictions in place."

Based on the latest data, the following public health unit regions will move from their current level in the framework to the following levels effective Monday, November 23, 2020 at 12:01 a.m.:

- Red-Control
  - Durham Region Health Department; and
  - Region of Waterloo Public Health and Emergency Services.

- Orange-Restrict
  - Huron Perth Public Health;
  - Simcoe Muskoka District Health Unit;
  - Southwestern Public Health; and
  - Windsor-Essex County Health Unit.

- Yellow-Protect
  - Chatham-Kent Public Health;
  - Eastern Ontario Health Unit;
  - Grey Bruce Health Unit;
  - Kingston, Frontenac and Lennox & Addington Public Health;
  - Peterborough Public Health; and
  - Thunder Bay District Health Unit.

Please visit Ontario.ca/covidresponse for the full list of public health region classifications.

Trends in public health data will continue to be reviewed weekly to determine if public health units should stay where they are or be moved into a higher level. Public health units will stay in their level for a minimum of 28 days, or two COVID-19 incubation periods, at which time, the government will assess the impact of public health measures to determine if the public health unit should stay where they are or be moved to a different level. The Ministry of Health will continue to communicate regularly with local medical officers of health on local context and conditions to help inform the classification of their public health unit region.

For long-term care homes, visitor restrictions apply to those homes in the public health units that are in the Orange-Restrict level or higher. To further protect the health and safety of those in long-term care homes, staff, essential caregivers and support workers who provide direct care to residents in those regions will be tested more frequently for COVID-19, moving from bi-weekly tests to weekly as of November 23, 2020. In addition, support workers who provide direct care and caregivers in those regions will be asked to provide proof of a negative COVID-19 test result in the past week and verbally attest that they have not subsequently tested positive.

For retirement homes, homes in public health regions that are in Red-Control or higher will be in high alert with visitor restrictions as outlined in the Retirement Homes COVID-19 Visitor Policy. Homes will continue to be notified of their alert status by the Retirement Homes Regulatory Authority.

"Advising regions to move into a lockdown is not a decision we take lightly, but it is one that is needed to ensure the safety of the people of Peel and Toronto," said Dr. Williams. "Now more than ever, it is critical that all Ontarians continue to follow public health advice to help stop the spread of the virus. Everyone has a role to play to protect each other. We are interdependent and nothing can be done without the commitment of each individual, family and community."

To further support public health regions, the province is making additional enforcement mechanisms available to local medical officers of health who have applied additional measures based on their local conditions and needs. The government is amending Ontario Regulation 950 under the *Provincial Offences Act*, allowing for a ticket to be issued for any contravention of a COVID-19 specific communicable disease class order issued by a medical officer of health. The government will also ask the Chief Justice of the Ontario Court of Justice to establish a set fine to be attached to any ticket issued for violating a section 22 order relating to COVID-19 made by a local medical officer of health.

"We are asking Ontarians to familiarize themselves with the restrictions in place, follow the rules and public health guidance, and support enforcement officers who are working to help prevent the further spread of COVID-19," said Solicitor General Sylvia Jones. "Our government will continue to work with law enforcement to ensure they have the tools they need to promote public safety and take the enforcement actions needed to prevent unsafe behaviour."

Additional Supports Available for Businesses Affected by COVID-19 Public Health Measures

The Ontario government is now providing $600 million in relief to support eligible businesses required to close or significantly restrict services due to enhanced public health measures, doubling its initial commitment of $300 million made in the 2020 Budget, Ontario's Action Plan: Protect, Support Recover.

Businesses can apply online for temporary property tax and energy cost rebate grants from the province, via an easy-to-use one-window portal. The rebates will cover the length of time that a business is required to temporarily close or significantly restrict services as a result of being located in an area categorized as Red-Control or Lockdown, or previously categorized as modified Stage 2 public health restrictions. Most businesses can expect to receive their rebate payments within a few weeks of submitting a complete application. A detailed list of eligible businesses, as well as instructions for applying, can be found at Ontario.ca/covidsupport.

The federal and provincial governments have been working collaboratively together to deliver benefits and supports to individuals, families and businesses since the onset of COVID-19. Consistent with this, Ontario will work with the federal government to ensure these supports for businesses in COVID-19 hotspots are available in the most straightforward and seamless way possible by integrating these rebates with the federal Canada Emergency Rent Subsidy (CERS) program.

"We will double the funding we have made available to support employers and jobs affected by the necessary public health measures we are taking to protect people during the second wave," said Minister Phillips. "All of us know a small business owner struggling due to COVID-19. These necessary public health measures we have outlined today will create new challenges — but as we committed in Ontario's Action Plan: Protect, Support, Recover, we will continue to be there to protect jobs and support employers."

NEWS RELEASE

Ontario Moving Regions to New Levels in COVID-19 Response Framework

Framework Introduces Preventative Measures Earlier to Limit Transmission of COVID-19

November 27, 2020
Health

TORONTO — The Ontario government, in consultation with the Chief Medical Officer of Health, local medical officers of health, and other health experts, is moving five public health regions to new levels with stronger public health measures. These steps are being taken to stop the spread of COVID-19 in order to keep schools open, safeguard health system capacity, and protect the province's most vulnerable populations. The regional levels and specific public health measures are set out in the *Keeping Ontario Safe and Open Framework*.

"The health and safety of all Ontarians is and will always be our top priority, that's why we are following the advice of the Chief Medical Officer of Health and other health experts and making this adjustment today," said Christine Elliott, Deputy Premier and Minister of Health. "Over the last week we have seen a shift in the trends of key public health indicators in regions across the province, and by moving these five regions to a new level in the framework, we can ensure that the necessary targeted measures are in place to stop the spread of the virus and allow us to keep our schools and businesses open."

Based on the latest data, the following public health regions will move from their current level in the framework to the following levels effective Monday, November 30, 2020 at 12:01 a.m.:

- Red-Control
  - Windsor-Essex County Health Unit.
- Orange-Restrict
  - Haldimand-Norfolk Health Unit.
- Yellow-Protect
  - Hastings Prince Edward Public Health
  - Lambton Public Health; and
  - Northwestern Health Unit.

All other public health regions will remain at their current level. Please visit Ontario.ca/covidresponse for the full list of public health region classifications.

For long-term care homes, visitor restrictions apply to those homes in the public health unit regions that are in the Orange-Restrict level or higher. In addition, long-term care homes must implement recently enhanced testing requirements.

Trends in public health data will continue to be reviewed weekly to determine if public health units should stay where they are or be moved into a higher level. Public health units will stay in their level for a minimum of 28 days, or two COVID-19 incubation periods, at which time, the government will assess the impact of public health measures to determine if the public health unit should stay where they are or be moved to a different level. The Ministry of Health will continue to consult regularly with local medical officers of health on local context and conditions to help inform the classification of their public health unit region.

"As we continue in our fight against this second wave of COVID-19, the need to follow public health advice has never been greater," said Dr. David Williams, Chief Medical Officer of Health. "All Ontarians are urged to adhere to the organized public event and social gathering limits in their region and avoid any non-essential travel in order to reduce the risk of exposure and ensure the continued safety of the community."

All Ontarians should avoid close contact with anyone not living in the same household. People who live alone may have exclusive close contact with one additional household to prevent feelings of isolation and mitigate against negative mental health impacts.

The following recommendations apply to all public health unit regions in the province:

- Stay home if you have COVID-19 symptoms, even if they are mild;
- Maintain two metres of physical distancing from everyone else;
- Avoid social gatherings and limit close contacts to your household or the people you live with;
- Adhere to the restrictions in your region on public and private gatherings;
- Wear a face covering indoors and wear one outdoors if physical distancing may not be maintained or if wearing one is required;
- Wash your hands thoroughly and regularly;
- Cover your cough;
- Get tested if you have symptoms compatible with COVID-19, or if you've been advised of exposure by your local public health unit or through the COVID Alert mobile app;
- Individuals and families from higher transmission regions should avoid travel to lower transmission regions, except for essential reasons; and
- Download the COVID Alert mobile app.

Quick Facts

- Find out what level and which regional public measures are in place for your area.
- No matter where you live in the province, the safest way to spend the holidays this year is by only celebrating in person with the people you live with and celebrating virtually with everyone else.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert app. Visit Ontario.ca/covidtest to find the nearest testing location.
- To find the right supports, visit COVID-19: Support for People, which has information about the many available and free mental health services and supports.
- The Ontario government is now providing $600 million in relief to support eligible businesses required to close or significantly restrict services due to enhanced public health measures, doubling its initial commitment of $300 million made in the 2020 Budget, Ontario's Action Plan: Protect, Support Recover.

NEWS RELEASE

Ontario Moving Regions to New Levels with Stronger Public Health Measures

Action is being taken to stop the spread of COVID-19 and protect vulnerable people

December 11, 2020
Health

TORONTO — The Ontario government, in consultation with the Chief Medical Officer of Health, local medical officers of health, and other health experts, is moving seven public health regions to new levels with stronger public health measures, including Windsor-Essex County Health Unit and York Region Public Health moving into Grey-Lockdown. These steps are being taken to stop the spread of COVID-19 in order to keep schools open in the regions where in-class learning is permitted, safeguard health system capacity, and protect the province's most vulnerable populations. The regional levels and specific public health measures are set out in the *Keeping Ontario Safe and Open Framework*.

"Moving a region into Grey-Lockdown is not an easy decision, but it is one we needed to make in order to help stop the spread of the virus and safeguard the key services we rely on," said Christine Elliott, Deputy Premier and Minister of Health. "As we enter the holiday season and as the province prepares to receive its first shipment of COVID-19 vaccines, it remains crucial for all Ontarians to continue adhering to public health advice and workplace safety measures to reduce the spread of the virus and keep each other safe."

Based on the latest data, the following public health regions will move from their current level in the framework to the following levels effective Monday, December 14, 2020 at 12:01 a.m.:

- Grey-Lockdown
  - Windsor-Essex County Health Unit; and
  - York Region Public Health.

- Red-Control
  - Middlesex-London Health Unit;
  - Simcoe Muskoka District Health Unit; and
  - Wellington-Dufferin-Guelph Public Health.

- Orange-Restrict
  - Eastern Ontario Health Unit.

- Yellow-Protect
  - Leeds, Grenville and Lanark District Health Unit.

All other public health regions will remain at their current level. Please visit Ontario.ca/covidresponse for the full list of public health region classifications.

"Over the last week, public health indicators in the York and Windsor regions have continued to trend in the wrong direction and it is evident additional measures are needed to help limit the spread of the virus," said Dr. David Williams, Chief Medical Officer of Health. "By making this difficult but necessary decision we can help to ensure that hospitals in these regions can work to provide patients with the care they need when they need it, including the performing of scheduled surgeries and other important procedures."

For long-term care homes, visitor restrictions apply to those homes in the public health unit regions that are in the Orange-Restrict level or higher. In addition, long-term care homes must implement recently enhanced testing requirements.

Trends in public health data will continue to be reviewed weekly to determine if public health units should stay where they are or be moved into a different level. Public health units will stay in their level for a minimum of 28 days, or two COVID-19 incubation periods, at which time, the government will assess the impact of public health measures to determine if the public

health unit should stay where they are or be moved to a different level. The government and the Chief Medical Officer of Health will continue to consult regularly with local medical officers of health on local context and conditions to help inform the classification of their public health unit region.

As we approach the holiday season, the government is urging all Ontarians to continue to follow all required public health measures and public health advice. This includes the following:

- Stay home if you have COVID-19 symptoms, even if they are mild;
- Maintain two metres of physical distancing from anyone outside your household;
- Avoid social gatherings and limit close contacts to your household or the people you live with;
- Adhere to the restrictions in your region on public and private gatherings;
- Wear a face covering indoors and wear one outdoors if physical distancing may not be maintained or if wearing one is required;
- Wash your hands thoroughly and regularly;
- Cover your cough;
- Get tested if you have symptoms compatible with COVID-19, or if you've been advised of exposure by your local public health unit or through the COVID Alert mobile app;
- Individuals and families from higher transmission regions should avoid travel to lower transmission regions, except for essential reasons; and
- Download the COVID Alert mobile app.

No matter where you live in the province, the safest way to spend the holidays this year is by only celebrating in person with the people you live with and celebrating virtually with everyone else. People who live alone may have exclusive close contact with one additional household to help prevent feelings of isolation and mitigate against negative mental health impacts.

The Ontario government is now providing $600 million in property tax and energy cost rebates to support eligible businesses required to close or significantly restrict services due to enhanced public health measures, doubling its initial commitment of $300 million made in the 2020 Budget, Ontario's Action Plan: Protect, Support, Recover. To apply for this funding please visit Businesses: Get help with COVID-19 costs.

Quick Facts

- Find out what level and which regional public measures are in place for your area.
- Learn how to celebrate the holidays safely with the people you live with by visiting Ontario.ca/celebratesafely.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert app. Visit Ontario.ca/covidtest to find the nearest testing location.
- To find the right supports, visit COVID-19: Support for People, which has information about the many available and free mental health services and supports.
- If you have questions about what will be open or impacts to your business or employment, call the Stop the Spread Business Information Line at 1-888-444-3659.
- To stay safe, you can download the COVID Alert App free from the Apple and Google Play app stores.

NEWS RELEASE

Ontario Announces Provincewide Shutdown to Stop Spread of COVID-19 and Save Lives

Government Providing Grants of up to $20,000 to Small Businesses Impacted by New Public Health Measures

December 21, 2020
Office of the Premier

TORONTO — As COVID-19 cases continue to rise at an alarming rate, the Ontario government, in consultation with the Chief Medical Officer of Health and other health experts, is imposing a Provincewide Shutdown. Additional restrictions will be put into place and reinforce that Ontarians should stay at home as much as possible to minimize transmission of the virus and prevent hospitals from becoming overwhelmed. The Provincewide Shutdown will go into effect as of Saturday, December 26, 2020, at 12:01 a.m.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Stephen Lecce, Minister of Education, Dr. David Williams, Chief Medical Officer of Health, and Dr. Naveed Mohammad, President and CEO, William Osler Health System.

"The number of daily cases continue to rise putting our hospitals and long-term care homes at risk," said Premier Ford. "We need to stop the spread of this deadly virus. That's why, on the advice of Dr. Williams and other health experts, we are taking the difficult but necessary decision to shutdown the province and ask people to stay home. Nothing is more important right now than the health and safety of all Ontarians."

In response to these exceptional circumstances, the Provincewide Shutdown would put in place time-limited public health and workplace safety measures similar to those in other jurisdictions. It would help stop the trend of high COVID-19 transmission in communities, preserve health system capacity, safeguard vulnerable populations and those who care for them, and save lives. Measures include, but are not limited to:

- Restricting indoor organized public events and social gatherings, except with members of the same household (the people you live with). Individuals who live alone may consider having exclusive close contact with one other household.
- Prohibiting in-person shopping in most retail settings - curbside pickup and delivery can continue. Discount and big box retailers selling groceries will be limited to 25 per cent capacity for in-store shopping. Supermarkets, grocery stores and similar stores that primarily sell food, as well as pharmacies, will continue to operate at 50 per cent capacity for in-store shopping.
- Restricting indoor access to shopping malls - patrons may only go to a designated indoor pickup area (by appointment only), essential retail stores that are permitted to be open (e.g. pharmacy, grocery store), or, subject to physical distancing and face covering requirements, to the food court for takeout purchases. Shopping malls may also establish outdoor designated pickup areas.
- Prohibiting indoor and outdoor dining. Restaurants, bars and other food or drink establishments will be permitted to operate by take out, drive-through, and delivery only.

On the advice of the Chief Medical Officer of Health, all Ontarians are advised to stay home as much as possible with trips outside the home limited to necessities such as food, medication, medical appointments, or supporting vulnerable community members. Employers in all industries should make every effort to allow employees to work from home.

The current COVID-19 Response Framework will be paused when the Provincewide Shutdown comes into effect. The impacts of these time-limited measures will be evaluated throughout the 14 days in Northern Ontario and 28 days in Southern Ontario to determine if it is safe to lift any restrictions or if they need to be extended.The Chief Medical Officer of Health will assess and apply lessons learned thus far to the COVID-19 Response Framework to ensure appropriate and effective measures are in place to protect the health of Ontarians and enable economic recovery after the Provincewide Shutdown ends. This will include an assessment of how a revised approach for the safe reopening of retail may be operationalized, according to the latest available evidence.

"This was not an easy decision before the holidays, but we have reached a tipping point," said Minister Elliott. "We continue to see sharp increases in hospitalizations and occupancy in intensive care units is reaching concerning levels. Urgent action must be taken to prevent our health care system from becoming overwhelmed. By implementing a Provincewide Shutdown, we can work to stop the virus in its tracks, safeguard hospital capacity, and save lives."

The government is also providing $12.5 million to implement a High Priority Communities Strategy to contain the virus in high-risk communities. The strategy will take a tailored, community-based approach to fund community agencies in 15 priority communities in the York, Peel, Durham, Ottawa, and Toronto regions. The funding will also allow for the hiring of community ambassadors to make people aware of available services and assistance, for coordination of increased testing opportunities and for the arrangement of wraparound supports for those who are COVID-positive. Additional funding of $42 million will also be available to establish isolation centres.

The province will work with our local municipal partners to establish new isolation centres to help those who may need to isolate following testing.

"We continue to see the number of cases in the province grow and the trends in public health indicators worsen. Additional measures are needed provincewide in order to interrupt this concerning growth," said Dr. Williams. "We must work together to enable everyone to follow these new and time-limited restrictions and protect our health system and our communities."

The government is working to limit the transmission of COVID-19 in workplaces by supporting essential businesses in doing whatever is necessary to keep workers safe. The Ministry of Labour, Training and Skills Development is leading a multi-ministry COVID-19 Safety Team. The team will partner with local authorities to carry out additional enforcement blitzes in sectors where they are needed most.

New School Protocols

While transmission in schools remains low, all publicly funded and private elementary and secondary schools are to move to teacher-led remote learning when students return from the winter break on January 4, 2021. This action is being taken in support of the Government's broader efforts to limit the spread of COVID-19.

Schools located in the following Public Health Unit regions can resume in-person instruction on January 11, 2021 for both elementary and secondary students:

- The District of Algoma Health Unit
- North Bay Parry Sound District Health Unit
- Northwestern Health Unit
- Porcupine Health Unit
- Sudbury and District Health Unit
- Thunder Bay District Health Unit
- Timiskaming Health Unit

For schools in all other Public Health Unit regions, elementary school students are planned to be able to return to in-person learning on January 11, 2021, and secondary school students will continue learning remotely until January 25, 2021, at which point they may resume in-person learning. During this period, child care centres, authorized recreational and skill building programs and home-based child care services will remain open. From January 4-8, 2021, when elementary students move to remote learning, before and after school programs will be closed and emergency child care for health care and frontline workers will be provided. As part of the government's efforts to protect the most vulnerable, boards will be required to make provisions for continued in-person support for students with special education needs who cannot be accommodated through remote learning for whom remote learning is challenging.

"While our schools are not a source of rising community transmission, we can play an important part of the solution to save lives from COVID-19," said Minister Lecce. "During this period, students will pivot to teacher-led online learning, with child care provided for our frontline workers. We are taking proactive and preventative action to protect schools following the holiday break to ensure kids can continue in-class learning — something we believe is so important — for the remainder of the year."

The New Ontario Small Business Support Grant

The government recognizes that small businesses impacted by these necessary public health measures will require additional support so they can continue serving their communities and employing people in Ontario once the COVID-19 pandemic is over. That is why the government is announcing the new *Ontario Small Business Support Grant*, which will provide a minimum of $10,000 and up to $20,000 to eligible small business owners to help navigate this challenging period.

"Ontario's business owners have shown remarkable resolve and ingenuity throughout the pandemic. They know better than anyone what they need to come through this very difficult time, so they can continue to serve and employ people in their communities," said Rod Phillips, Minister of Finance. "The new *Ontario Small Business Support Grant* will provide significant financial support to eligible small business owners in addition to the other supports made available to our small business community."

Small businesses required to close or restrict services under the Provincewide Shutdown will be able to apply for this one-time grant. Each small business will be able to use the support in whatever way makes the most sense for their individual business. For example, some businesses will need support paying employee wages or rent, while others will need support maintaining their inventory.

Eligible small businesses include those that:

- Are required to close or significantly restrict services subject to the Provincewide Shutdown effective 12:01 a.m. on December 26, 2020;
- Have less than 100 employees at the enterprise level; and
- Have experienced a minimum of 20 per cent revenue decline in April 2020 compared to April 2019.

Starting at $10,000 for all eligible businesses, the grant will provide businesses with dollar for dollar funding to a maximum of $20,000 to help cover decreased revenue expected as a result of the Provincewide Shutdown. The business must demonstrate they experienced a revenue decline of at least 20 per cent when comparing monthly revenue in April 2019 and April 2020. This time period was selected because it reflects the impact of the public health measures in spring 2020, and as such provides a representation of the possible impact of these latest measures on small businesses.

Essential businesses that are allowed to remain open will not be eligible for this grant. More information about the *Ontario Small Business Support Grant* is available here. Further details, including how to apply, will be announced in January 2021.

Businesses that are impacted by the Provincewide Shutdown will also be eligible for the property tax and energy cost rebates. In November, the government launched a program to provide rebates to offset fixed costs such as property tax and energy bills for businesses that are required to shut down or significantly restrict services due to provincial public health measures. These rebates will continue to be available for businesses impacted by the Provincewide Shutdown and earlier restrictions. Business can apply for the rebates here.

Quick Facts

- Currently, hospitalizations for COVID-19 have increased by 74 per cent over the last four weeks and are more than 15 times higher than they were at the beginning of September. Intensive care unit (ICU) occupancy for COVID-19 has more than doubled over the last four weeks and is 20 times higher than at the beginning of September.
- Ontario currently has 915 COVID-19 patients requiring acute care, 265 patients in ICU, with 152 on a ventilator.
- Based on the latest modelling data, cases across the province are continuing to grow and the number of people requiring an intensive care bed is projected to rise well above 300 people within the next 10 days.
- Some jurisdictions around the world, including those in Canada have implemented similar time-limited measures to respond to a dramatic resurgence in cases. Based on their experiences, measures of four to six weeks are expected to interrupt transmission of COVID-19 in Ontario.
- Municipalities and local medical officers of health may have additional restrictions or targeted requirements in their region.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert App. Visit Ontario.ca/covidtest to find the nearest testing location.
- The Ontario Small Business Support Grant is part of the Province's more than $13.5 billion in support for people and jobs outlined in the 2020 Budget, Ontario's Action Plan: Protect, Support, Recover. It is also in addition to $4.8 billion to address critical areas to support a strong long-term recovery that helps workers, employers and communities get back on their feet, while building the foundation for recovery and growth.
- To find the right supports, visit COVID-19: Support for People, which has information about the many available and free mental health services and supports.
- To stay safe you can download the COVID Alert App free from the Apple and Google Play app stores.
- To date, as part of the province's COVID-19 immunization program, over 3,000 frontline health care workers have been vaccinated.
- Schools continue to be safe, and according to data reported by school boards, as of Friday, December 18: approximately 99.64 per cent of students in Ontario have not reported a case of COVID-19; approximately 92 per cent of schools across the province have had either no cases or one case reported within the last 14 days; and approximately 80 per cent of schools do not have an case of COVID-19.

NEWS RELEASE

Ontario Declares Second Provincial Emergency to Address COVID-19 Crisis and Save Lives

Province Issues Stay-at-Home Order and Introduces Enhanced Enforcement Measures to Reduce Mobility

January 12, 2021
Office of the Premier

TORONTO — In response to a doubling in COVID-19 cases over the past two weeks, the real and looming threat of the collapse of the province's hospital system and alarming risks posed to long-term care homes as a result of high COVID-19 transmission rates, the Ontario government, in consultation with the Chief Medical Officer of Health and other health experts, is immediately declaring a second provincial emergency under s 7.0.1 (1) of the *Emergency Management and Civil Protection Act* (EMPCA).

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Solicitor General Sylvia Jones, Dr. David Williams, Chief Medical Officer of Health, and Dr. Adalsteinn (Steini) Brown, Co-Chair of the Ontario COVID-19 Science Advisory Table.

"The latest modelling data shows that Ontario is in a crisis and, with the current trends, our hospital ICUs will be overwhelmed in a few short weeks with unthinkable consequences," said Premier Ford. "That's why we are taking urgent and decisive action, which includes declaring a provincial emergency and imposing a stay-at-home-order. We need people to only go out only for essential trips to pick up groceries or go to medical appointments. By doing the right thing and staying home, you can stay safe and save lives."

Effective Thursday, January 14, 2021at 12:01 a.m., the government is issuing a stay-at-home order requiring everyone to remain at home with exceptions for permitted purposes or activities, such as going to the grocery store or pharmacy, accessing health care services, for exercise or for work where the work cannot be done remotely. This order and other new and existing public health restrictions are aimed at limiting people's mobility and reducing the number of daily contacts with those outside an immediate household. In addition to limiting outings for these purposes, all businesses must ensure that any employee who can work from home, does work from home.

These new public health measures will help stop the spread of COVID-19 by reducing concerning levels of mobility as the province continues its vaccine rollout and ramps up to mass vaccination when the federal government is able to provide the necessary supply to do so.

Additional Public Health Restrictions

Since the implementation of the Provincewide Shutdown over two weeks ago, the latest modelling trends in key public health indicators have continued to worsen, forecasting an overwhelming of the health system unless drastic action is taken. Escalating case counts have led to increasing hospitalization rates and intensive care unit (ICU) occupancy which has resulted in cancellations of scheduled surgeries and procedures.

Provincial modelling shows growth in COVID-19 cases has accelerated, leading to increased hospitalization rates and ICU occupancy. ICU occupancy by COVID-19 patients is now over 400 beds and is projected to be as high as 1,000 beds by early February which has the potential to overwhelm Ontario's hospitals. The number of COVID-19-related deaths continues to rise and is expected to double from 50 to 100 deaths per day between now and the end of February. Notably, data shows that mobility and contacts between people have not decreased with the current restrictions. A new variant of COVID-19 emerged in November. If community transmission of this variant occurs, Ontario could experience much higher case counts, ICU occupancy and mortality.

In response to the alarming and exceptional circumstances at hand, and to further interrupt the deadly trend of transmission in Ontario communities, hospitals, and long-term care homes, the following additional public health measures will take effect January 13, 2021 at 12:01 a.m.:

- Outdoor organized public gatherings and social gatherings are further restricted to a limit of five people with limited exceptions. This is consistent with the rules during the lockdown during the first wave of COVID-19 in spring 2020 and will allow individuals and families to enjoy time outdoors safely.
- Individuals are required to wear a mask or face covering in the indoor areas of businesses or organizations that are open. Wearing a mask or face covering is now recommended outdoors when you can't physically distance more than two metres.
- All non-essential retail stores, including hardware stores, alcohol retailers, and those offering curbside pickup or delivery, must open no earlier than 7 a.m. and close no later than 8 p.m. The restricted hours of operation do not apply to stores that primarily sell food, pharmacies, gas stations, convenience stores, and restaurants for takeout or delivery.
- Non-essential construction is further restricted, including below-grade construction, exempting survey.

These measures will come into effect between Tuesday January 12, 2021 and Thursday, January 14, 2021, including the provincial declaration of emergency under the EMCPA, orders under that Act, and amendments to regulations under the *Reopening Ontario (A Flexible Response to COVID-19) Act, 2020*.

"Despite our best efforts, COVID-19 is continuing to spread in our communities, our hospitals, our long-term care homes, and our workplaces. We are continuing to see concerning trends across the province, including a tragic number of deaths," said Christine Elliott, Deputy Premier and Minister of Health. "We have made great strides in vaccinating tens of thousands of Ontarians, and we can't let these efforts go to waste. Urgent action is required to break this deadly trend of transmission, ensure people stay home, and save lives."

To help quickly identify and isolate cases of COVID-19 in workplaces and service providers permitted to remain open such as long-term care homes and schools, the province will provide up to 300,000 COVID-19 tests per week to support key sectors such as manufacturing, warehousing, supply chain and food processing, as well as additional tests for schools and long-term care homes. This volume of rapid tests would support antigen screening for up to 150,000 workers per week over the next 4-5 months in Ontario's most critical workplaces. The province is expecting to receive 12 million Panbio tests from the federal government over the next several months and continues to pursue opportunities to purchase additional rapid tests.

"The trends in key public health indicators are continuing to deteriorate, and further action is urgently required to save lives," said Dr. David Williams, Chief Medical Officer of Health. "By strictly adhering to all public health and workplace safety measures, we can reduce the transmission of COVID-19 and keep our loved ones and our communities safe. It will take the collective efforts of us all to defeat this virus."

The government knows that in order to keep Ontarians safe, it is important that they are not forced to leave their homes during the new state of emergency. Ontario is exploring all options available to put a temporary residential evictions moratorium in place, and will have more to say in the coming days.

The additional public health restrictions introduced expand on the existing measures put in place to keep Ontarians safe and healthy.

New Enforcement Measures

The province will provide authority to all provincial offences officers, including the Ontario Provincial Police, local police forces, bylaw officers, and provincial workplace inspectors to issue tickets to individuals who do not comply with the stay-at-home-order, or those not wearing a mask or face covering indoors in places open to the public, subject to limited exceptions, as well as retail operators and companies who do not enforce requirements under orders under the *Reopening Ontario (A Flexible Response to COVID-19) Act* (ROA) or EMPCA. Those who decide not to abide by orders will be subject to a set fine and/or prosecution under both the ROA and EMCPA as applicable.

In addition, all provincial offences officers will have the authority to temporarily close a premise and disperse individuals who are in contravention of gathering limits an order and will be able to disperse people who are gathering, regardless whether a premise has been closed or remains open such as a park.

"Strong, new measures will be enforced to stop the spread of COVID-19," said Solicitor General Sylvia Jones. "We are taking extraordinary action to provide law enforcement officers with the tools and support they need to protect the health and wellbeing of Ontarians."

Schools and Child Care Centres

Based on the advice of the Chief Medical Officer of Health, schools in the following public health units (PHUs) will not return to in-person instruction until February 10, 2021:

- Windsor-Essex

- Peel Region
- Toronto
- York
- Hamilton

By January 20, 2021, the Chief Medical Officer of Health will advise the Ministry of Education on which public health units (PHUs) will be permitted to resume in-person instruction, based on the most up-to-date data and modelling. Before- and after-school programs can be offered when in-person instruction resumes. Schools in northern PHUs will continue to remain open.

To continue to keep students, staff and communities safe, the following new health and safety measures will be put in place for in-person learning:

- Masking for Grade 1-3 and requirements for mask wearing outdoors;
- Enhanced screening protocols; and
- Expanded targeted testing.

The government will also implement new health and safety measures in Ontario child care settings, such as enhanced screening to align with school requirements, voluntary participation in targeted testing and additional infection prevention and control measures to align with schools. These enhancements are in addition to the existing health and safety measures already being implemented in child care settings across the province.

Child care centres for non-school aged children will remain open, and emergency child care for school-aged children will end in approved PHU regions on January 22, 2021 as these elementary schools return to in-person learning.During this extended period of online learning, in areas where in-person elementary learning is suspended, emergency child care will continue for eligible families in regions subject to school closures, as identified by the Chief Medical Officer of Health.

"At the heart of our continued efforts to protect against the spread of COVID-19 in our communities is a firm commitment to return kids to school safely," said Education Minister Stephen Lecce. "Protecting our students, staff and their families is our top priority, and these additional measures build on our comprehensive plan to reopen schools and keep young children in child care safe."

Workplace Safety

The Ministry of Labour, Training and Skills Development is taking additional steps to protect workers with the launch of the "Stay Safe All Day" campaign, focusing workplace inspections in areas of high transmission, including break rooms, and providing new educational materials to employers to

promote safe behaviour before, during and after work.

Evidence gathered from COVID-19 related workplace inspections to date shows the vast majority of employers and workers are following COVID-19 safety requirements when working. However, when in a break room, a vehicle or not on the clock, there is a tendency to forget about the importance of wearing masks, maintaining physical distance and hand hygiene.

As part of the "Stay Safe All Day" campaign, inspectors will use a data-driven approach to focus on workplaces with reported COVID-19 outbreaks, manufacturing businesses, warehouses, distribution centres, food processing operations, construction projects and publicly accessible workplaces deemed essential, such as grocery stores. The Ministry is also using a new data-sharing program, in conjunction with the Ministry of Long-Term Care and the Retirement Regulatory Authority, to focus onsite inspections of long-term-care homes and retirement homes.

"We know the majority of businesses are operating safely and responsibly to protect their workers and customers. But as COVID-19 cases continue to rise, we all need to step up and take additional measures to stop the spread," said Monte McNaughton, Minister of Labour, Training and Skills Development. "This includes increasing our inspections to look at everything workers do both while on the job and throughout the workday."

In the unfortunate event that an employee becomes infected with COVID-19, they may be entitled to federally funded paid sick leave of up to $500 a week for two weeks. Workers can also access Canada's Recovery Caregiver Benefit of up to $500 per week for up to 26 weeks if they are unable to work because they must care for their child under 12 years old or a family member who needs supervised care.

Over the summer, the government enacted a new regulatory amendment that put non-unionized employees on Infectious Disease Emergency Leave during the COVID-19 outbreak any time their hours of work are temporarily reduced by their employer due to COVID-19, ensuring businesses aren't forced to terminate employees after their ESA temporary layoff

periods have expired. As part of the Safe Restart Agreement, the federal government is funding a temporary income support program that allows workers to take up to 10 days of leave related to COVID-19, preventing the risk of further spread in the workplace and allowing workers to focus on their health.

Quick Facts

- The Government of Ontario declared its first provincial emergency in response to COVID-19 on March 17, 2020 which remained in effect until July 24, 2020 when the ROA came into force.
- An emergency declaration pursuant to s. 7.0.1 is terminated 14 days after being made and may be extended for up to a further 14 days by the Lieutenant Governor in Council. Thereafter, extensions require approval of the Legislature, which can extend the declared provincial emergency for additional periods of up to 28 days. Orders made during the declaration of emergency pursuant s. 7.0.2 (4) will automatically terminate after 14 days unless they are extended for additional periods of up to 14 days, while orders pursuant to s. 7.1 can be for a period of up to 90 days and renewed for additional periods of up to 90 days.
- The orders currently in force under the Reopening Ontario (A Flexible Response to COVID-19) Act, 2020 (ROA) remain in effect until January 20, 2021. Under the ROA, orders can be extended for up to 30 days at a time, and the government must continue to report on all order extensions to the Select Committee on Emergency Management Oversight.
- A full list of emergency orders under the EMPCA as well as orders under the ROA can be found on the e-Laws website and at Ontario.ca/alert.
- As of January 10, 2021, there have been 215,782 reported COVID-19 cases and 4,983 related deaths in Ontario.
- Ontario has implemented the largest immunization plan in its history and to date, a total of over 130,000 doses have been administered provincewide.
- Building on the efforts of the targeted testing in Phase 1, the Ministry of Education and the Ministry of Health will work together with Ontario Health, PHUs and school boards to expand access to COVID-19 testing.

NEWS RELEASE

Ontario Extending Stay-at-Home Order across Most of the Province to Save Lives

Public Health Units to Gradually Return to the COVID-19 Response Framework

February 08, 2021
Office of the Premier

TORONTO — In consultation with the Chief Medical Officer of Health, the government is moving to a regional approach and maintaining the shutdown in the majority of the public health regions in Ontario, including the Stay-at-Home order and all existing public health and workplace safety measures. When it is safe to do so, the province will gradually transition each region from the shutdown measures to a revised and strengthened *COVID-19 Response Framework: Keeping Ontario Safe and Open* (the "Framework").

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Solicitor General Sylvia Jones, and Dr. David Williams, Chief Medical Officer of Health.

"Our number one priority will always be protecting the health and safety of all individuals, families and workers across the province," said Premier Ford. "But we must also consider the severe impact COVID-19 is having on our businesses. That's why we have been listening to business owners, and we are strengthening and adjusting the Framework to allow more businesses to safely reopen and get people back to work."

To support the province's economic recovery, the government has updated the Framework to allow for a safer approach to retail. Limited in-person shopping in Grey-Lockdown zones will be permitted with public health and safety measures, such as limiting capacity to 25 per cent in most retail settings. In addition, public health and safety measures in retail settings will be strengthened for other levels of the Framework. Individuals will also be required to wear a face covering and maintain physical distance when indoors in a business, with limited exceptions.

Other measures include a requirement for individuals to wear a face covering when attending an organized public event or gathering (where permitted) if they are within two metres distance of another individual who is not part of their household (both indoor and outdoor). All other requirements for gatherings and organized public events would be maintained.

Based on the improving local trends of key indicators, including lower transmission of COVID-19, improving hospital capacity, and available public health capacity to conduct rapid case and contact management, the following three regions will be moving back to the Framework at the Green-Prevent level on Wednesday, February 10, 2021 at 12:01 a.m. and will no longer be subject to the Stay-at-Home order:

- Hastings Prince Edward Public Health;
- Kingston, Frontenac and Lennox & Addington Public Health; and
- Renfrew County and District Health Unit.

Due to the fact that public health trends are improving in some regions faster than others, the current Stay-at-Home order will be amended and individual orders making it applicable to each public health region will be made except for the three above. It is proposed that the Stay-at-Home order will continue to apply to 28 public health regions until Tuesday, February 16, 2021. For Toronto, Peel and York regions, it is proposed that the Stay-at-Home order will continue to apply until Monday, February 22, 2021. Final decisions will be subject to review of the trends in public health indicators at that time.

"While we have seen some progress in our fight against COVID-19, the situation in our hospitals remains precarious and the new variants pose a considerable threat to all of us," said Minister Elliott. "As we cautiously and gradually transition out of the provincewide shutdown, we have developed an emergency brake system giving us the flexibility to contain community spread quickly in a specific region, providing an extra layer of protection."

Recognizing the risk posed by new variants to the province's pandemic response, Ontario is introducing an "emergency brake" to allow for immediate action if a public health unit region experiences rapid acceleration in COVID-19 transmission or if its health care system risks becoming overwhelmed. If this occurs, the Chief Medical Officer of Health, in consultation with

the local medical officer of health, may advise immediately moving a region into Grey-Lockdown to interrupt transmission.

"While we are seeing our numbers trend in the right direction, our situation remains precarious as the variants of concern remain a serious risk," said Dr. Williams. "This is not a re-opening or a 'return to normal' and we must continue to limit close contact to our immediate households and stay at home except for essential reasons. By continuing to follow all public health and workplace safety measures, we can continue to reduce the number of new cases and the strain on our health system."

In addition, the provincial emergency declared under s 7.0.1 of the *Emergency Management and Civil Protection Act* (EMPCA) will be allowed to terminate at the end of February 9, 2021. While the provincewide Stay-at-Home order will cease to apply in some regions as of February 10, 2021, everyone is strongly advised to continue to stay at home, avoid social gatherings, minimize travel between areas with different rules, and limit close contacts to their household. Employers in all industries should continue to make every effort to allow employees to work from home.

Enforcement of residential evictions will remain paused in the public health unit regions where the provincial Stay-at-Home order remains in effect. This will ensure people are not forced to leave their homes. In regions where the Stay-at-Home order is lifted, the regular process for residential eviction enforcement will resume.

Orders currently in force under the EMCPA have been extended to February 23, 2021 and will be extended further if necessary. O.Reg.55/21 (Compliance Orders for Retirement Homes) is currently in effect until February 19, 2021.

"While the declaration of emergency will be ending, the risks posed by COVID-19 and the new variants remain serious concerns," said Solicitor General Jones. "That's why extending the stay-at-home orders for most of the province is necessary to protect our communities, our most vulnerable populations, and stop the spread of COVID-19. We continue to urge all Ontarians to follow public health guidelines and stay home, stay safe, and save lives."

The Chief Medical Officer of Health will continue to consult with public health and other experts, review data, and provide advice to the government on the appropriate and effective measures that are needed to protect the health of Ontarians. Municipalities and local medical officers of health may have additional restrictions or targeted requirements in their region.

Quick Facts

- Provincewide Shutdown measures went into effect on December 26, 2020 to stop the rapid spread of COVID-19 across the province.
- The government declared its second provincial emergency on January 12, 2021 and issued a Stay-at-Home order to reduce mobility and address hospital capacity concerns.
- Ontario has implemented a six-point plan to deal with the new variants which includes mandatory on-arrival testing of international travellers, enhanced screening and sequencing, maintaining public health measures to keep people safe, strengthening case and contact management to track the spread of new cases, enhanced protections for vulnerable populations, and leveraging the latest data to inform public health decisions.
- In January, Ontario's provincial offences officers visited 1,147 big-box stores and other essential retail businesses to ensure businesses are following the public health guidelines and properly protecting workers and customers from COVID-19. 112 tickets were issued to businesses and individuals during three inspection campaigns.
- To support the safe return of in-person learning, Ontario has introduced new measures to continue to protect students and staff against COVID-19 in the classroom.
- Once the shutdown is lifted, visitor restrictions for long-term care homes will once again apply to those homes in the public health regions that are in the Orange-Restrict level or higher. In addition, long-term care homes must implement enhanced testing requirements.
- A full list of emergency orders under the EMPCA as well as orders under the ROA can be found on the e-Laws website and at Ontario.ca/alert.

NEWS RELEASE

Ontario Returning 27 Public Health Regions to Strengthened COVID-19 Response Framework

Province Extending Shutdown and Stay-at-Home Order in Regions at Highest Risk

February 12, 2021
Health

TORONTO — In consultation with the Chief Medical Officer of Health, the Ontario government is transitioning twenty-seven public health regions out of the shutdown and into a revised and strengthened *COVID-19 Response Framework: Keeping Ontario Safe and Open* (the "Framework"). The four remaining public health regions, Toronto Public Health, Peel Public Health, York Region Public Health and North Bay Parry Sound District, will remain in the shutdown, and the Stay-at-Home order and all existing public health and workplace safety measures will continue to apply to these four public health regions.

"The health and safety of Ontarians remains our number one priority. While we are cautiously and gradually transitioning some regions out of shutdown, with the risk of new variants this is not a reopening or a return to normal," said Christine Elliott, Deputy Premier and Minister of Health. "Until vaccines are widely available, It remains critical that all individuals and families continue to adhere to public health measures and stay home as much as possible to protect themselves, their loved ones and their communities."

Based on a general improvement in trends of key indicators, including lower transmission of COVID-19, improving hospital capacity, and available public health capacity to conduct rapid case and contact management, the following public health regions will be moving back to the Framework on Tuesday, February 16, 2021 at 12:01 a.m. and will no longer be subject to the Stay-at-Home order:

Grey-Lockdown:

- Niagara Region Public Health

Red-Control:

- Chatham-Kent Public Health;
- City of Hamilton Public Health Services;
- Durham Region Health Department;
- Halton Region Public Health;
- Middlesex-London Health Unit;
- Region of Waterloo Public Health and Emergency Services;
- Simcoe-Muskoka District Health Unit;
- Southwestern Public Health;
- Thunder Bay District Health Unit;
- Wellington-Dufferin Guelph Public Health; and
- Windsor-Essex County Health Unit.

Orange-Restrict:

- Brant County Health Unit;

- Eastern Ontario Health Unit;
- Haldimand-Norfolk Health Unit;
- Haliburton, Kawartha, Pine Ridge District Health Unit;
- Huron Perth Public Health;
- Lambton Public Health;
- Ottawa Public Health;
- Porcupine Health Unit; and
- Public Health Sudbury and Districts.

Yellow-Protect:

- Algoma Public Health;
- Grey Bruce Health Unit;
- Northwestern Health Unit; and
- Peterborough Public Health.

Green-Prevent:

- Leeds, Grenville and Lanark District Health Unit; and
- Timiskaming Health Unit.

For North Bay Parry Sound District, Peel Public Health, Toronto Public Health and York Region Public Health, it is proposed that the shutdown measures and the Stay-at-Home order will continue to apply until at least Monday, February 22, 2021. Please visit Ontario.ca/covidresponse for the full list of public health region classifications.

After returning to the Framework, public health regions will stay in their level for at least two weeks at which time, the government will assess the impact of public health and workplace safety measures to determine if the region should stay where they are or be moved to a different level. Public health regions will move up through the levels, if necessary, based on the set indicators and thresholds outlined in the Framework.

Visitor restrictions for long-term care homes will once again apply to those homes in the public health regions that are in the Orange-Restrict level or higher. In addition, long-term care homes must implement enhanced testing requirements.

Recognizing the risk posed by new variants to the province's pandemic response, Ontario is introducing an "emergency brake" to allow the Chief Medical Officer of Health, in consultation with the local medical officer of health, to immediately advise moving a region into Grey-Lockdown to interrupt transmission. Local medical officers of health also have the ability to issue Section 22 orders under the *Health Protection and Promotion Act*, to target specific transmission risks in the community.

"While the trends in public health indicators are heading in the right direction, we still have work to do," said Dr. David Williams, Chief Medical Officer of Health. "Everyone is strongly advised to continue staying at home, avoid social gatherings, only travel between regions for essential purposes, and limit close contacts to your household or those you live with."

The Chief Medical Officer of Health will continue to consult with public health and other experts, review data, and provide advice to the government on the appropriate and effective measures that are needed to protect the health of Ontarians.

Quick Facts

- Find out what level and which regional public measures are in place for your area.
- On February 10, 2021, Hastings Prince Edward Public Health, Kingston, Frontenac and Lennox & Addington Public Health, and Renfrew County and District Health Unit moved to the Framework at the Green-Prevent level.

- To help stop the spread of COVID-19 and safeguard health system capacity, Ontarians are strongly urged to continue staying at home and limit trips outside their household and between other regions for essential reasons only, not to gather with individuals outside of their household, and to wear a face covering when within two metres distance of another individual who is not part of their household (both indoor and outdoor) or when required, with limited exceptions.
- Ontario has implemented a six-point plan to deal with the new variants of concern which includes mandatory on-arrival testing of international travelers, enhanced screening and sequencing, maintaining public health measures to keep people safe, strengthening case and contact management to track the spread of new cases, enhanced protections for vulnerable populations, and leveraging the latest data to inform public health decisions.
- To support the province's economic recovery, the government has updated the Framework to allow for a safer approach to retail. Limited in-person shopping in Grey-Lockdown zones will be permitted with public health and safety measures, such as limiting capacity to 25 per cent in most retail settings.
- Digital tools have been an important part of the provincial response to COVID-19. To date, almost 6 million self-assessments have been completed using Ontario's health screening tool to help Ontarians navigate their symptoms and decide on next steps. Now, revised and updated screening tools for workers/employees and customer/visitors will help keep Ontarians safe and healthy by pre-screening for symptoms before leaving for work or to visit a business as the province re-opens. The tools help workplaces and businesses meet screening requirements.
- To support the safe return of in-person learning, Ontario has introduced new measures to continue to protect students and staff against COVID-19 in the classroom.

NEWS RELEASE

Stay-at-Home Order Extended in Toronto and Peel Public Health Regions Along with North Bay-Parry Sound

York Region to Return to Strengthened COVID-19 Response Framework

February 19, 2021
Health

TORONTO — In consultation with the Chief Medical Officer of Health and the local medical officers of health, the Ontario government is maintaining the shutdown, the Stay-at-Home order and all existing public health and workplace safety measures for an additional two weeks in the Toronto and Peel Public Health Regions, along with the North Bay-Parry Sound District. The York Public Health Region will transition out of the shutdown and into the revised and strengthened *COVID-19 Response Framework: Keeping Ontario Safe and Open*.

"Our government's number one priority is the safety of all individuals and families, and that's why we are taking a gradual, cautious approach to returning regions to the Framework," said Christine Elliott, Deputy Premier and Minister of Health. "These are difficult but necessary decisions, in order to protect against COVID-19 variants and maintain the progress we have all made together. Until vaccines are widely available, we continue to urge all Ontarians to follow public health advice and measures, and stay home, stay safe, and save lives."

In the Toronto and Peel Public Health Regions, and the North Bay-Parry Sound District, the shutdown measures and the Stay-at-Home order will continue to apply until at least Monday, March 8, 2021, based on key public health indicators and following consultation with the local medical officers of health. While the Peel and Toronto regions have seen a reduction in COVID-19 transmission from the period of February 8 to 17, 2021, rates still remain too high in the regions, with case rates of 83.4 cases per 100,000 people for Peel and 67.9 cases per 100,000 people for Toronto, both well above the provincial average. During this same period of time, North Bay Parry Sound District has also seen its case rate increase by 11.5 per cent to 14.6 cases per 100,000 people. Variants of concern also remain a serious risk to community transmission and health system capacity.

Based on a general improvement in trends of key indicators, York Region Public Health will be moving back to the Framework at the Red-Control level and will no longer be subject to the Stay-at-Home order. In addition, Lambton Public Health will be moving from the Orange-Restrict level to the Red-Control level as a result worsening public health trends in the region over the past week. These changes will come into effect on Monday, February 22, 2021 at 12:01 a.m.

After returning to the Framework, public health regions are required to stay in their level for at least two weeks. The government will then assess the impact of public health and workplace safety measures to determine if the region should stay where it is or be moved to a different level. Public health regions may be moved to a higher level within the two-week window, if necessary, based on the set indicators and thresholds outlined in the Framework. In addition, Ontario has introduced an "emergency brake" to allow the Chief Medical Officer of Health, in consultation with the local medical officer of health, to immediately advise moving a region into Grey-Lockdown to interrupt transmission.

"While the health indicators have improved enough to allow us to return an additional region to the Framework, we are not yet at the point where we can safely transition back the remainder of the province," said Dr. David Williams, Chief Medical Officer of Health. "Everyone is strongly advised to continue staying at home, avoid social gatherings, only travel between regions for essential purposes, and limit close contacts to your household or those you live with regardless of which level of the Framework you are in."

The Chief Medical Officer of Health will continue to consult with public health and other experts, review data, and provide advice to the government on the appropriate and effective measures that are needed to protect the health of Ontarians.

Quick Facts

- Find out what level and which regional public measures are in place for your area.

- On February 8th the government announced an extension of the shutdown in the majority of public health regions in Ontario and a gradual transition of each region to a revised and strengthened COVID-19 Response Framework when it is safe to do so.
- In addition to the Stay-at-Home orders that apply to the North Bay-Parry Sound District, Toronto and Peel public health regions, the following orders currently in force under the Emergency Management and Civil Protection Act (EMCPA) will be extended to March 8, 2021 and further if necessary: O.Reg 55/21 (Compliance Orders for Retirement Homes), O.Reg 8/21 (Enforcement of COVID-19 Measures), O.Reg. 11/21 (Stay-at-Home Order), O.Reg. 13/21 (Residential Evictions).
- Enforcement of residential evictions will remain paused in the public health regions where the provincial Stay-at-Home order remains in effect.
- Local medical officers of health continue to have the ability to issue Section 22 orders under the Health Protection and Promotion Act, to target specific transmission risks in the community.
- Ontario has implemented a six-point plan to prevent and stop the spread of COVID-19 variants.
- To support the safe return of in-person learning, Ontario has introduced new measures to continue to protect students and staff against COVID-19 in the classroom.

Additional Resources

- Please visit Ontario.ca/covidresponse for the full list of public health region classifications.
- To find the right supports, visit COVID-19: Support for People, which has information about the many available and free mental health services and supports.
- Get tested if you have COVID-19 symptoms, or if you have been advised of exposure by your local public health unit or through the COVID Alert App. Visit Ontario.ca/covidtest to find the nearest testing location.
- Visit Ontario's COVID-19 vaccine web page to view the latest provincial data and information on COVID-19 vaccines.

NEWS RELEASE

Ontario Activates Emergency Brake in Thunder Bay District Health Unit and Simcoe-Muskoka District Health Unit

Nine Public Health Regions Moving to New Levels in the COVID-19 Response Framework

February 26, 2021
Health

TORONTO — The Ontario government, in consultation with the Chief Medical Officer of Health, is moving nine public health regions to new levels in the *Keeping Ontario Safe and Open Framework* (the "Framework"). This includes activating an "emergency brake" in Thunder Bay District Health Unit and Simcoe-Muskoka District Health Unit to move the regions to Grey-Lockdown to immediately interrupt transmission and contain community spread. Decisions were made in consultation with the local medical officers of health and are based on the trends in public health indicators and local context and conditions.

"While we continue to see the number of cases and other public health indicators lowering in many regions across the province, the recent modelling shows us that we must be nimble and put in place additional measures to protect Ontarians and stop the spread of COVID-19," said Christine Elliott, Deputy Premier and Minister of Health. "With COVID-19 variants continuing to spread in our communities, it is critically important that everyone continues strictly adhering to all public health and workplace safety measures to help contain the virus and maintain the progress we have made to date."

Based on the latest data, the following public health regions will move from their current level in the Framework to the following levels effective Monday, March 1, 2021 at 12:01 a.m.:

Grey-Lockdown

- Simcoe-Muskoka District Health Unit; and
- Thunder Bay District Health Unit.

Red-Control

- Niagara Region Public Health.

Orange-Restrict

- Chatham-Kent Public Health;
- Middlesex-London Health Unit; and
- Southwestern Public Health.

Yellow-Protect

- Haldimand-Norfolk Health Unit; and
- Huron Perth Public Health.

Green-Prevent

- Grey Bruce Health Unit.

Based on the latest assessment of data the "emergency brake" is being used to place Thunder Bay District Health Unit and Simcoe-Muskoka District Health Unit into Grey-Lockdown, helping to stop the spread of the virus and protect public health and health system capacity in the regions. This is due to a rapid worsening in key public health indicators, as well as a high presence of variants in the Simcoe-Muskoka District Health Unit that continue to increase - the highest in the province. As of February 23, 2021, there has been a total of 170 confirmed cases of a variant of concern in this region.

In Peel Public Health, Toronto Public Health, and North Bay Parry Sound District, the Shutdown measures and the Stay-at-Home order will continue to apply until at least Monday, March 8, 2021, with final decisions to be based on key public health indicators and consultation with the local medical officers of health. All other public health regions will remain at their current level. Please visit Ontario.ca/covidresponse for the full list of public health region classifications.

Based on the latest modelling data, the efforts of Ontarians in following public health measures and advice are working to decrease the number of new cases, deaths and hospitalizations across the province. However, with variants of concern continuing to spread, the number of patients requiring hospitalization and intensive care may rise once again if public health measures are not relaxed carefully and gradually. The actions of everyone over the coming weeks will be critical to maintaining the progress communities have made across the province to date.

"Quickly implementing stronger measures to interrupt transmission of COVID-19 is a key component of the government's plan to safely and gradually return public health regions to the Framework," said Dr. David Williams, Chief Medical Officer of Health. "Due to data and local context and conditions in the Simcoe-Muskoka and Thunder Bay Districts, it was necessary to tighten public health measures in these regions to ensure the health and safety of the region at large and stop the spread of the virus."

The Chief Medical Officer of Health will continue to consult with public health and other experts, review data, and provide advice to the government on the appropriate and effective measures that are needed to protect the health of Ontarians.

Quick Facts

- Find out what level and which public health and workplace safety measures are in place for your area.
- To help stop the spread of COVID-19 and safeguard health system capacity, everyone is strongly urged to continue staying at home and limit trips outside their household and between other regions for essential reasons only, not to gather with individuals outside of their household, and to wear a face covering when within two metres distance of another individual who is not part of their household (both indoor and outdoor) or when required, with limited exceptions.
- Recognizing the risk posed by new variants to the province's pandemic response, Ontario has introduced an "emergency brake" to allow the Chief Medical Officer of Health, in consultation with the local medical officer of health, to immediately advise moving a region into Grey-Lockdown to interrupt transmission.
- Local medical officers of health continue to have the ability to issue Section 22 orders under the Health Protection and Promotion Act, and municipalities may enact by-laws, to target specific transmission risks in the community.
- Ontario has implemented a six-point plan to prevent and stop the spread of COVID-19 variants.

Additional Resources

- Stay-at-Home Order Extended in Toronto and Peel Public Health Regions Along with North Bay-Parry Sound.
- To find the right supports, visit COVID-19: Support for People, which has information about the many available and free mental health services and supports.
- Get tested if you have COVID-19 symptoms, or if you have been advised of exposure by your local public health unit or through the COVID Alert App. Visit Ontario.ca/covidtest to find the nearest testing location.
- Visit Ontario's COVID-19 vaccine web page to view the latest provincial data and information on COVID-19 vaccines.
- Visit Ontario's COVID-19 information website to learn more about how the province continues to protect the people of Ontario from the virus.

NEWS RELEASE

Toronto, Peel and North Bay-Parry Sound Public Health Regions Returning to Strengthened COVID-19 Response Framework

Seven Other Public Health Regions Moving to New Levels in the Framework

March 05, 2021
Health

TORONTO — The Ontario Government, in consultation with the Chief Medical Officer of Health, is transitioning Toronto, Peel and North Bay Parry Sound District public health regions out of the shutdown and into the revised and strengthened *COVID-19 Response Framework: Keeping Ontario Safe and Open* (the "Framework"), with the Stay-at-Home order no longer in effect. In addition, seven other public health regions are being moved to new levels in the Framework. All decisions were made in consultation with the local medical officers of health and are based on the latest trends in public health indicators and local context and conditions.

"Our government is taking a safe and cautious approach to returning to the Framework and due to our progress, all regions of the province will soon be out of the provincewide shutdown," said Christine Elliott, Deputy Premier and Minister of Health. "Despite this positive step forward, a return to the Framework is not a return to normal. As we continue vaccinating more Ontarians, it remains critical for everyone to continue to follow public health measures and stay home as much as possible to protect themselves, their loved ones and their communities."

Based on a general improvement in trends of key indicators, North Bay Parry Sound District will be returning to the Framework at the Red-Control level. Toronto Public Health and Peel Public Health are also making progress, but as their case rates still remain high, they will return to the Framework at the Grey-Lockdown level.

In addition, based on the latest data, the following seven public health regions will also be moving to the following levels in the Framework:

Red-Control

- Peterborough Public Health;
- Public Health Sudbury and Districts; and
- Simcoe-Muskoka District Health Unit.

Orange-Restrict

- Haldimand-Norfolk Health Unit; and
- Timiskaming Health Unit.

Yellow-Protect

- Haliburton, Kawartha, Pine Ridge District Health Unit; and
- Renfrew County and District Health Unit.

All changes will be effective Monday, March 8, 2021 at 12:01 a.m. Please visit Ontario.ca/covidresponse for the full list of public health region classifications.

Based on the latest modelling data, the efforts of Ontarians in following public health measures and advice are working to decrease the number of new cases, deaths and hospitalizations across the province. However, with COVID-19 variants of concern continuing to spread, the actions of everyone over the coming weeks will be critical to maintaining the progress communities have made across the province to date.

"While all regions have returned to the Framework, everyone must remain vigilant to help prevent any further increases in transmission," said Dr. David Williams, Chief Medical Officer of Health. "The best defense against the virus and all of its variants of concern remains continuing to stay at home, avoiding social gatherings, only travelling outside of your community for essential purposes, and limiting close contacts to your household or those you live with."

The Chief Medical Officer of Health will continue to consult with public health and other experts, review data, and provide advice to the government on the appropriate and effective measures that are needed to protect the health of Ontarians.

Quick Facts

- Find out what level and which public health and workplace safety measures are in place for your area.
- From the period of February 23 to March 2, 2021, case rates in North Bay Parry Sound District have decreased by 84.6 per cent to 3.1 cases per 100,000 people and the number of hospitalizations has shrunk from 1 to 0.
- In Toronto Public Health the case rates have decreased by 15.7 per cent to 66.4 cases per 100,000 people and hospitalizations have seen an 11.2 per cent decrease. During this same period of time, Peel Public Health has seen its case rates increase by 6.6 per cent to 91.4 cases per 100,000 people. Peel Region has also seen the number of patients with COVID-19 in intensive care decrease from 26 to 19.
- To help stop the spread of COVID-19 and safeguard health system capacity, everyone is strongly urged to continue staying at home and limit trips outside their household and to other regions for essential reasons only, and not to gather with individuals outside of their household. In addition, people are required to wear a face covering when within two metres distance of another individual who is not part of their household (both indoor and outdoor), with limited exceptions.
- Recognizing the risk posed by new variants to the province's pandemic response, Ontario has introduced an "emergency brake" to allow the Chief Medical Officer of Health, in consultation with the local medical officer of health, to immediately advise moving a region into Grey-Lockdown to interrupt transmission.
- Local medical officers of health continue to have the ability to issue Section 22 orders under the Health Protection and Promotion Act, and municipalities may enact by-laws, to target specific transmission risks in the community.
- Emergency orders O.Reg 8/21 (Enforcement of COVID-19 Measures) and O.Reg 55/21 (Compliance Orders for Retirement Homes) currently in force under the Emergency Management and Civil Protection Act (EMCPA) will be extended to March 22, 2021. Emergency orders O.Reg 11/21 (Stay-at-Home Order), O.Reg.89/21 (Stay-at-Home Order Toronto Public Health), O.Reg. 76/21 (Stay-at-Home Order North Bay Parry Sound District), O.Reg. 73/21 (Stay-at-Home Order Peel Public Health) and O.Reg 13/21 (Residential Evictions) will expire and no longer be in effect as of March 8, 2021.

NEWS RELEASE

Ontario Activates Emergency Brake in Sudbury Public Health Region

Immediate action required to interrupt transmission, contain community spread and save lives

March 11, 2021
Health

TORONTO — On the advice of the Chief Medical Officer of Health, the Ontario Government is activating an "emergency brake" in the Public Health Sudbury and Districts region, and moving it to the Grey-Lockdown level in the *Keeping Ontario Safe and Open Framework*. The decision was made due to the concerning trends in public health indicators and in consultation with the local medical officer of health.

"Implementing an emergency brake to immediately interrupt transmission of COVID-19 is a key component of our government's plan to safely and gradually return public health regions to the Framework," said Christine Elliott, Deputy Premier and Minister of Health. "We have seen a rapid rise in the case rate in the Sudbury area, and swift action is needed to protect individuals, families and businesses and save lives."

Based on the latest assessment of data, the "emergency brake" is being used to stop the spread, guard against variants and protect public health and health system capacity in the region. From March 3 to 9, 2021, the region's case rate increased by 54.1 per cent to 75.9 cases per 100,000 people.

The public health region will move to Grey-Lockdown effective Friday, March 12, 2021 at 12:01 a.m.

"As a result of the rapid deterioration of trends in key indicators, the emergency brake is being applied to move Public Health Sudbury and Districts to Grey-Lockdown to help reduce further spread of the virus in the region," said Dr. David Williams, Chief Medical Officer of Health. "We must remain vigilant in adhering to all public health and workplace safety measures to combat the threat posed by variants of concern."

The Chief Medical Officer of Health will continue to consult with public health and other experts, review data, and provide advice to the government on the appropriate and effective measures that are needed to protect the health of Ontarians.

Update on COVID-19 Projections

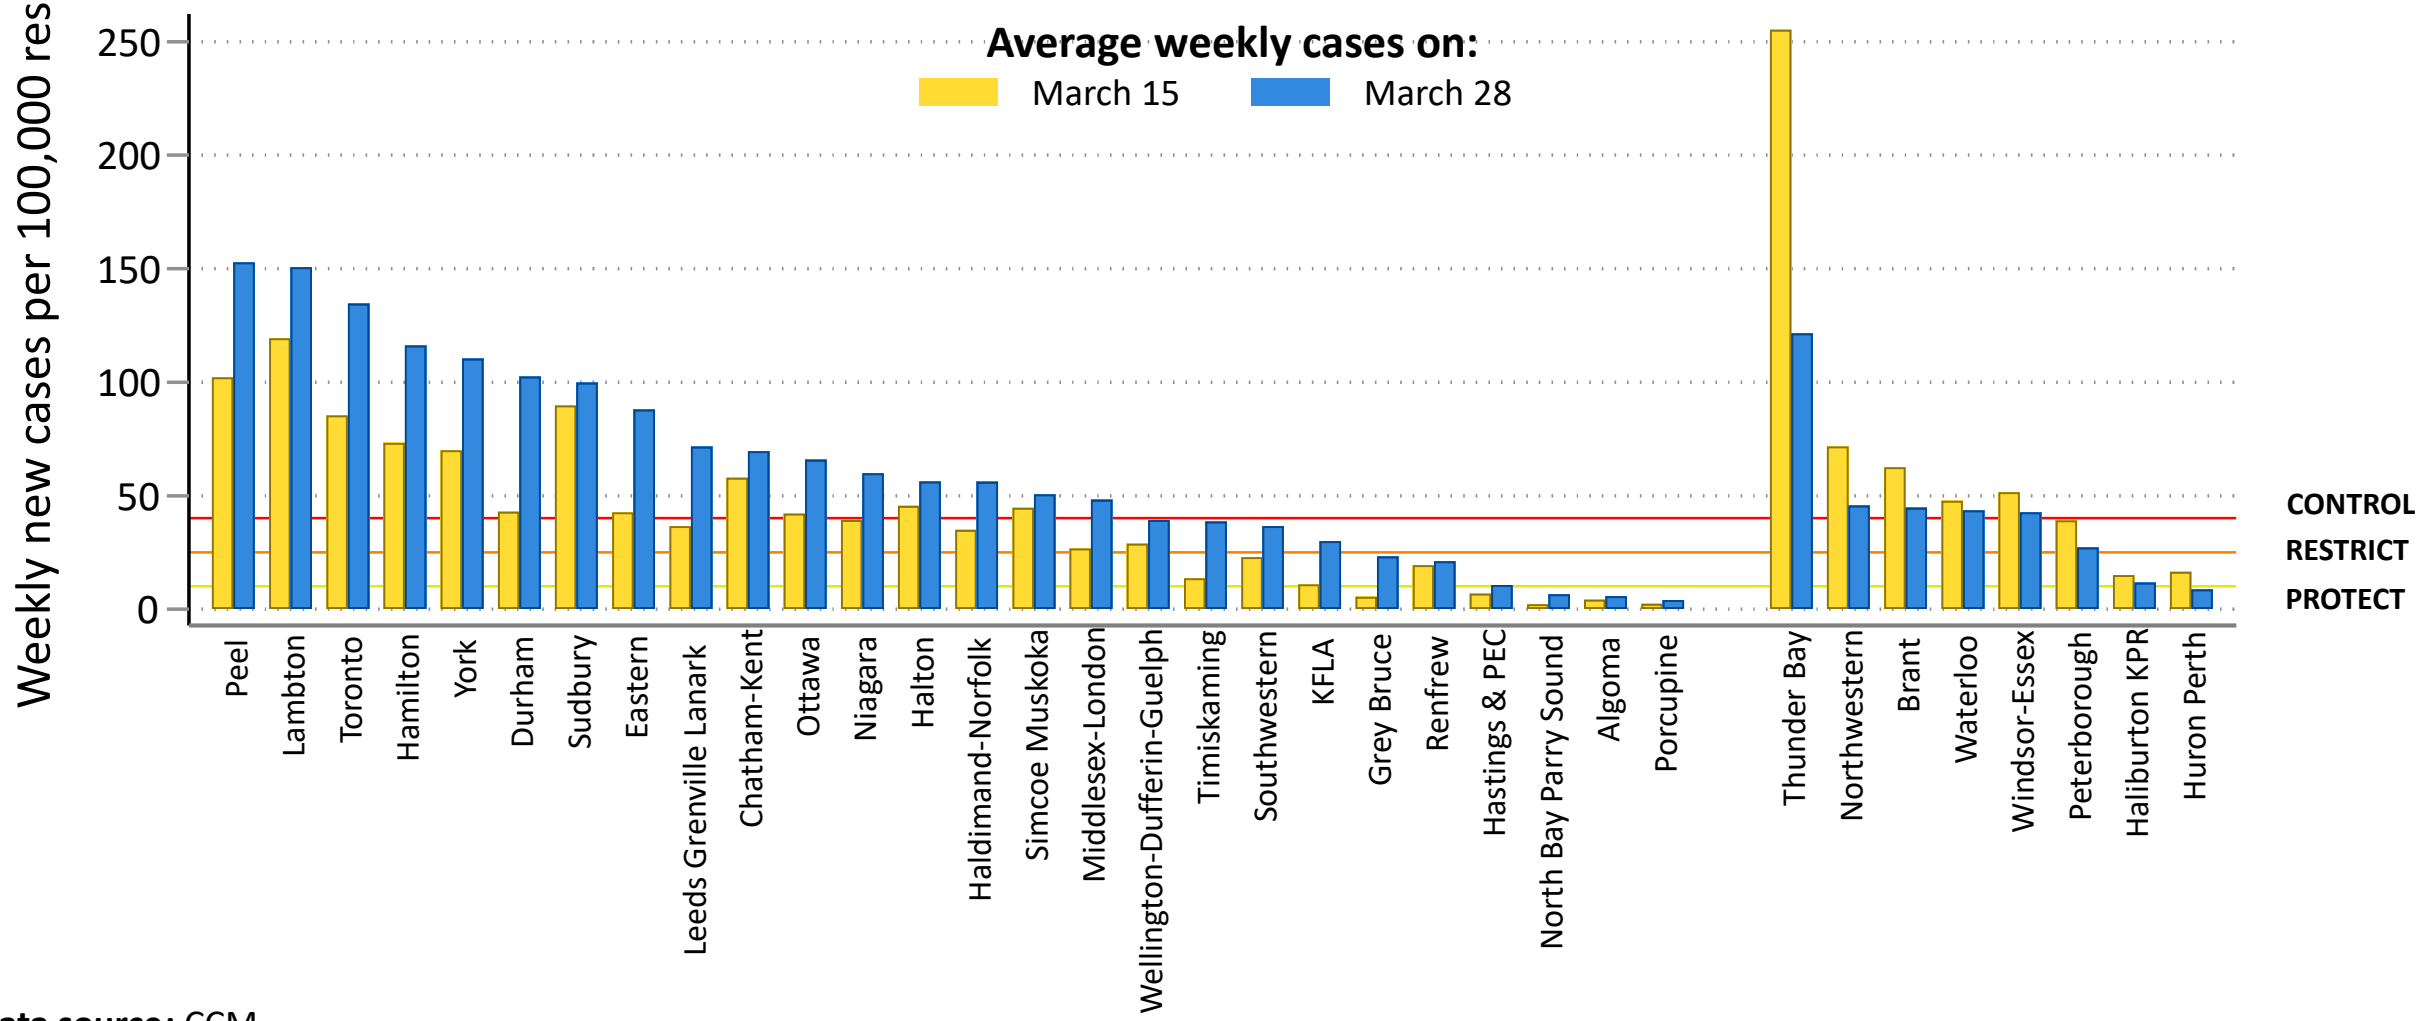
Science Advisory and Modelling Consensus Tables

April 1, 2021

Key Findings

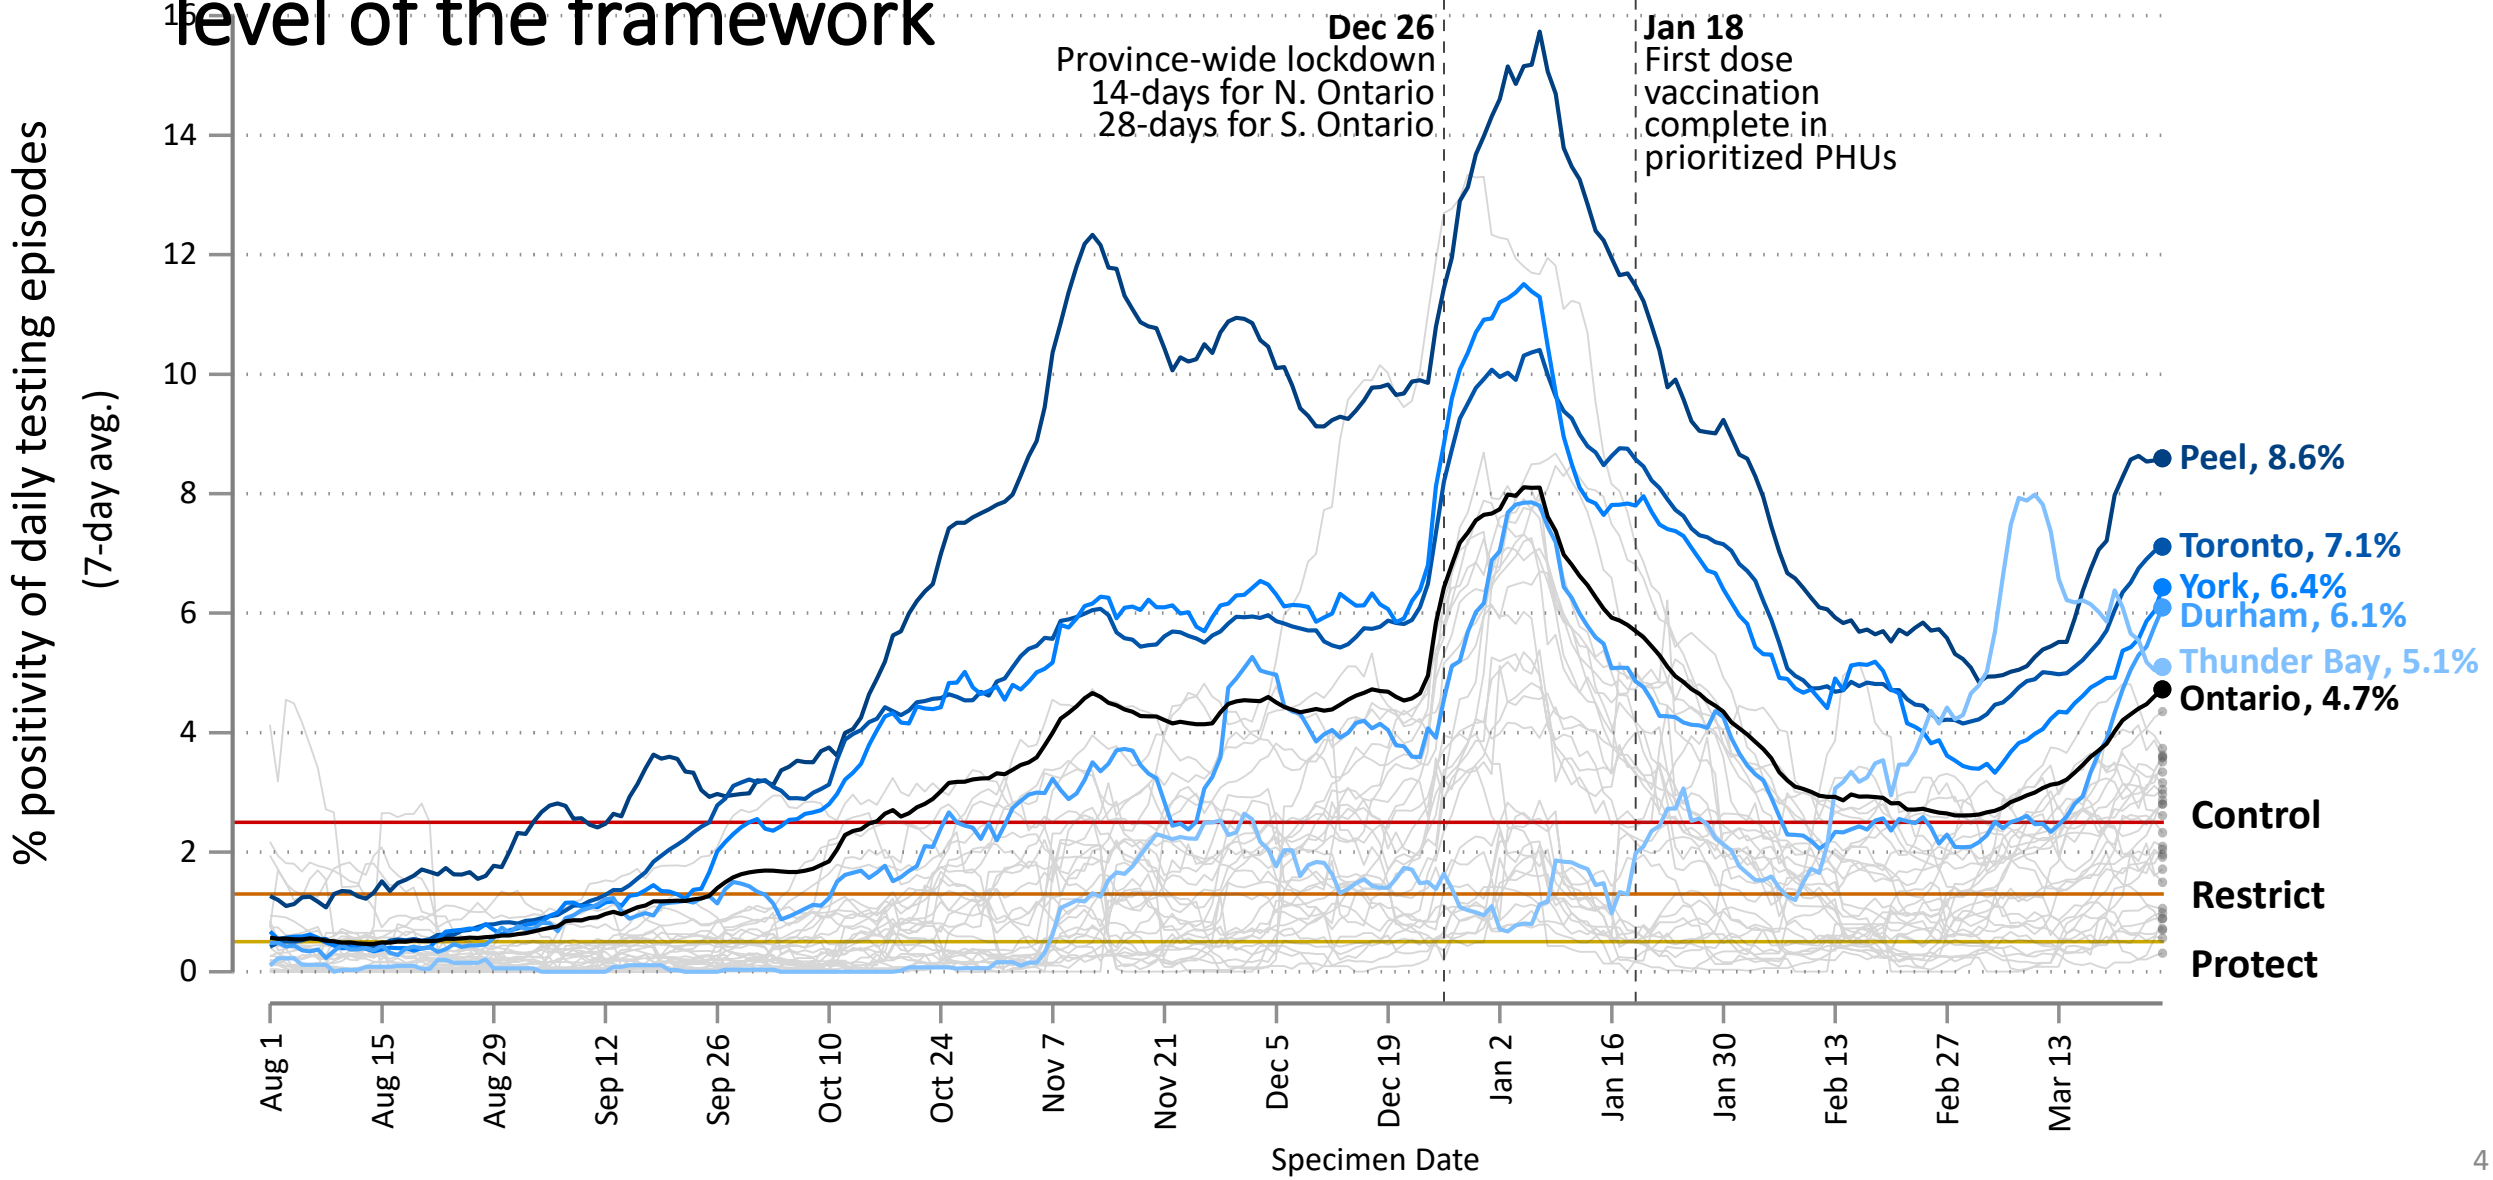
- The **third wave** is here and being **driven by variants of concern**.
- **Younger Ontarians are ending up in hospital.** Risk of ICU admission is **2 x higher** and risk of death is **1.5 x higher** for the B.1.1.7 variant.
- COVID-19 **threatens health system ability to deal with regular ICU admissions** and the ability to care for all patients.
- Vaccination is **not reaching the highest risk communities**, delaying its impact as an effective strategy.
- School disruptions have a significant and highly inequitable **impact** on students, parents and society. Further disruptions should be minimized.
- Stay-at-home orders will control the surge, protect access to care, and increase the chance of the summer Ontarians want.

Cases have increased and are above the second highest level of the framework in most Public Health Units



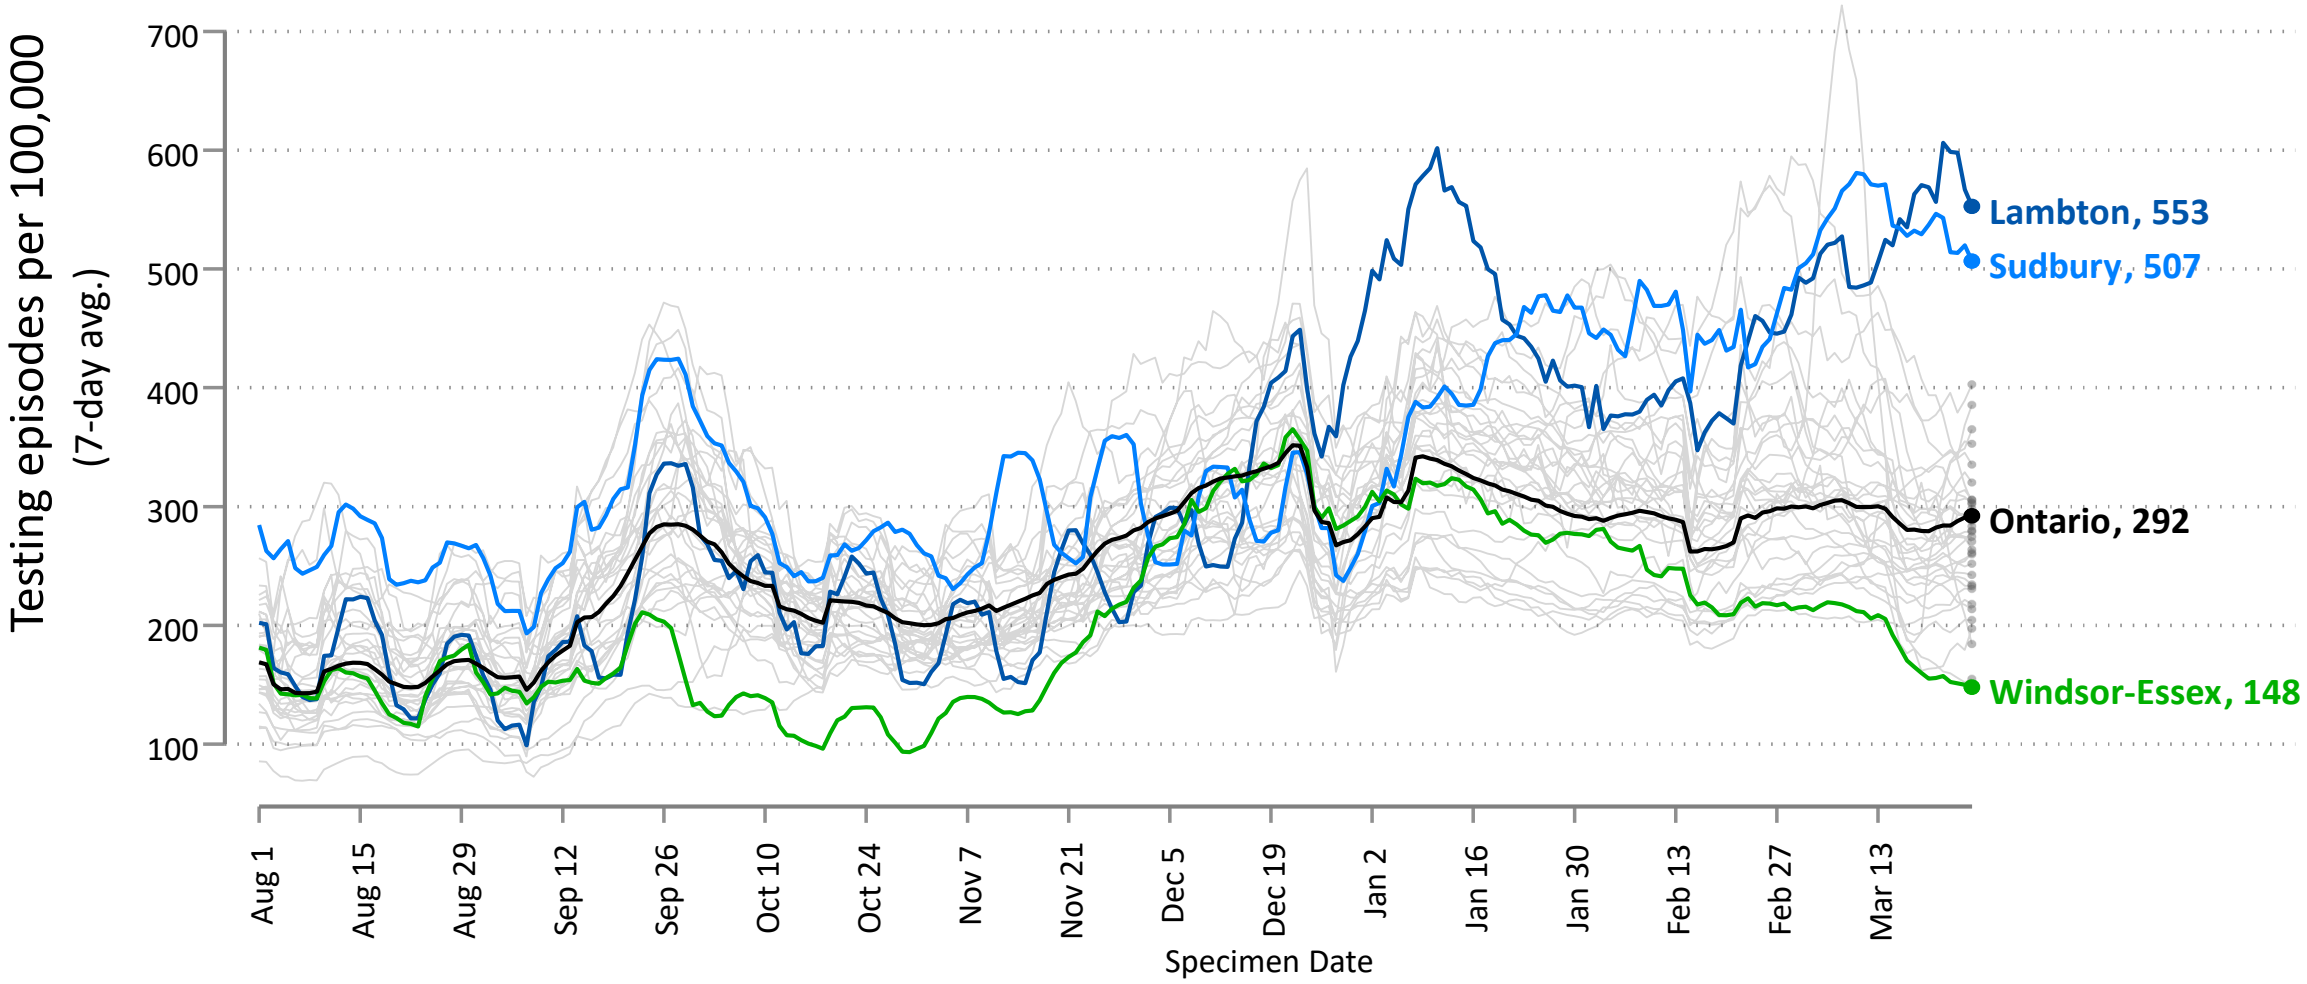
Data source: CCM
Data note: Data for the most recent day have been censored to account for reporting delays

Testing % positivity has increased and is above the second highest level of the framework



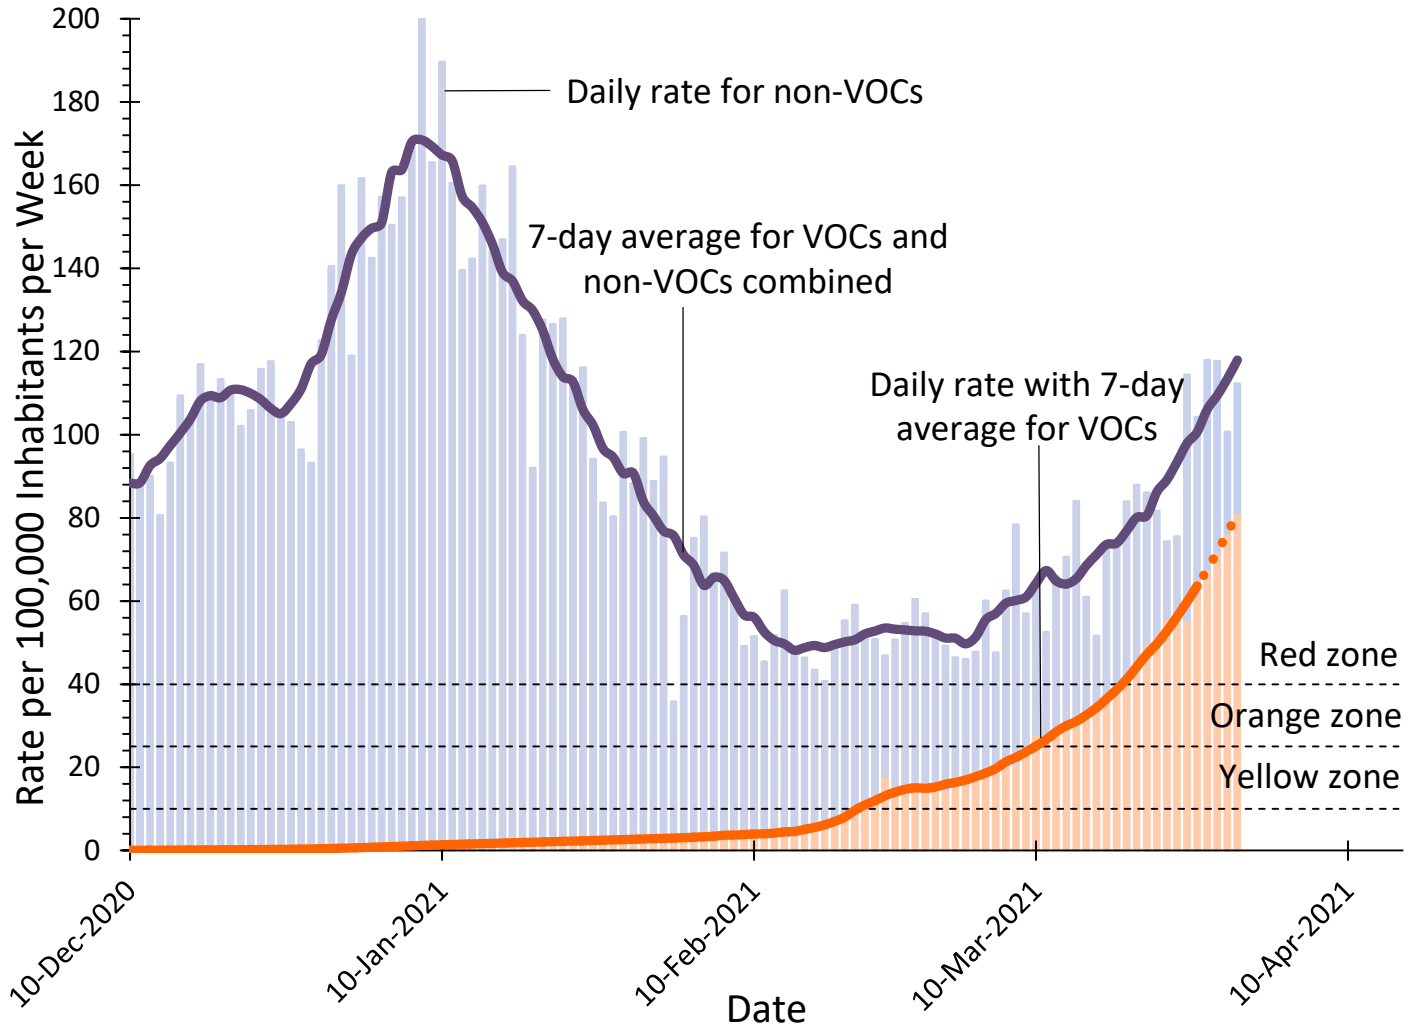
Data source: Ontario Laboratory Information System (OLIS), data up to March 26

Testing rates are flat so case growth is not a result of more testing



Data source: Ontario Laboratory Information System (OLIS), data up to March 26

Cases are increasing. Most new cases are variants of concern.



Variants of concern have more severe consequences and are more fatal

Compared to people infected with the earlier variants, more people with COVID-19 are hospitalized, admitted to ICU, and die if they are infected with the variants of concern.

Short-term case projections depend entirely on system-level public health measures and vaccination

Figure shows example, representative of predictions across 4 models, 3-5 scenarios each.

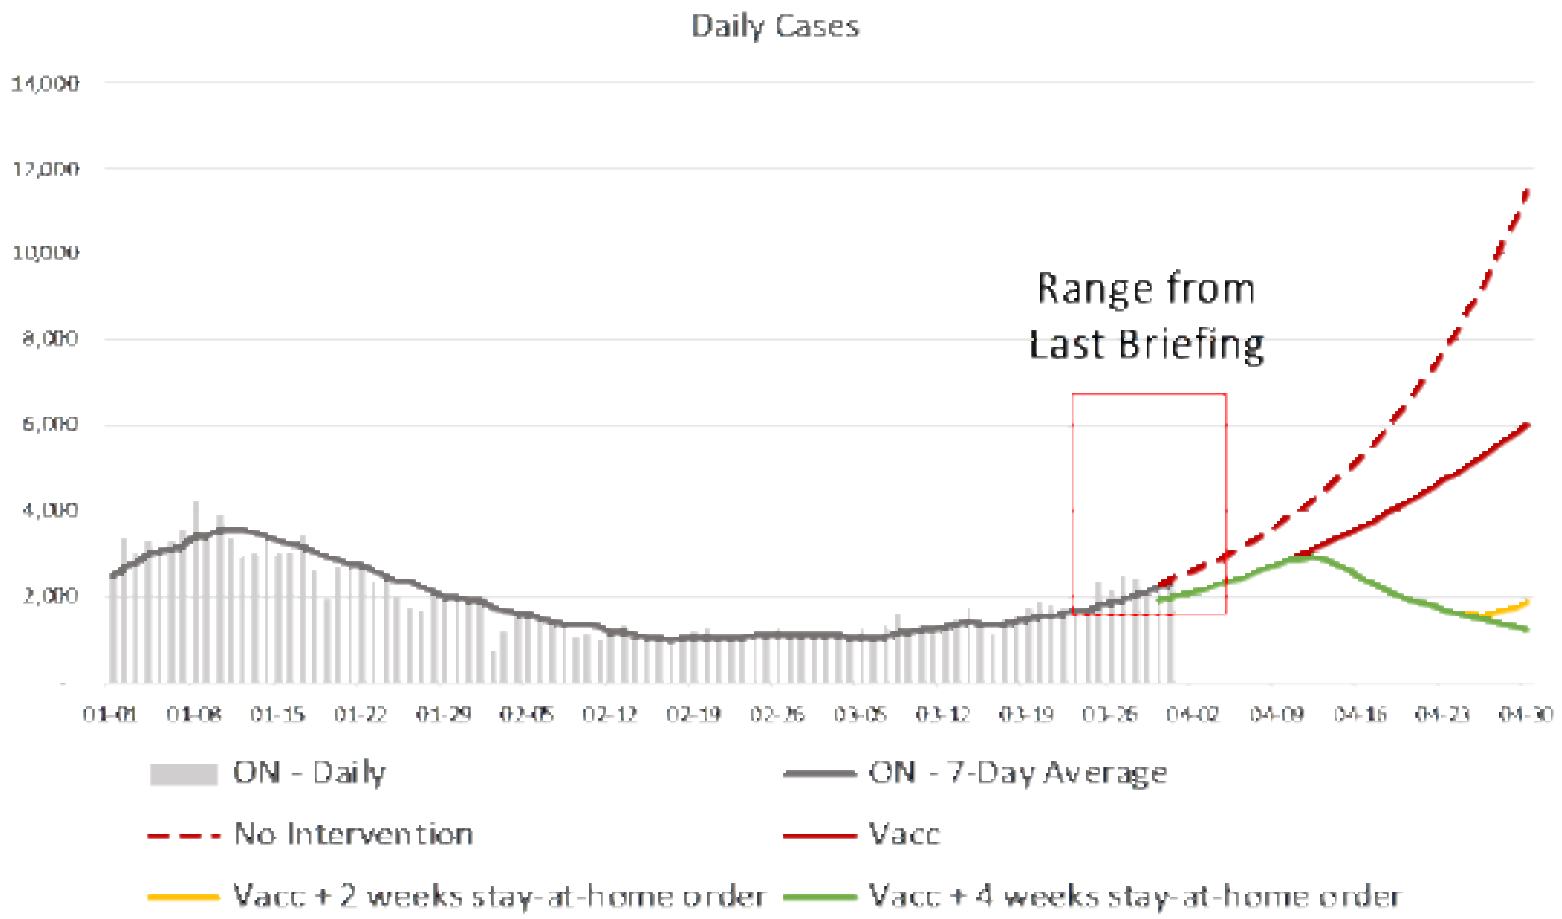
Scenarios:

Stay-at-home order assumptions:

- No stay-at-home
- 2 weeks starting Apr 5
- 4 weeks starting Apr 5

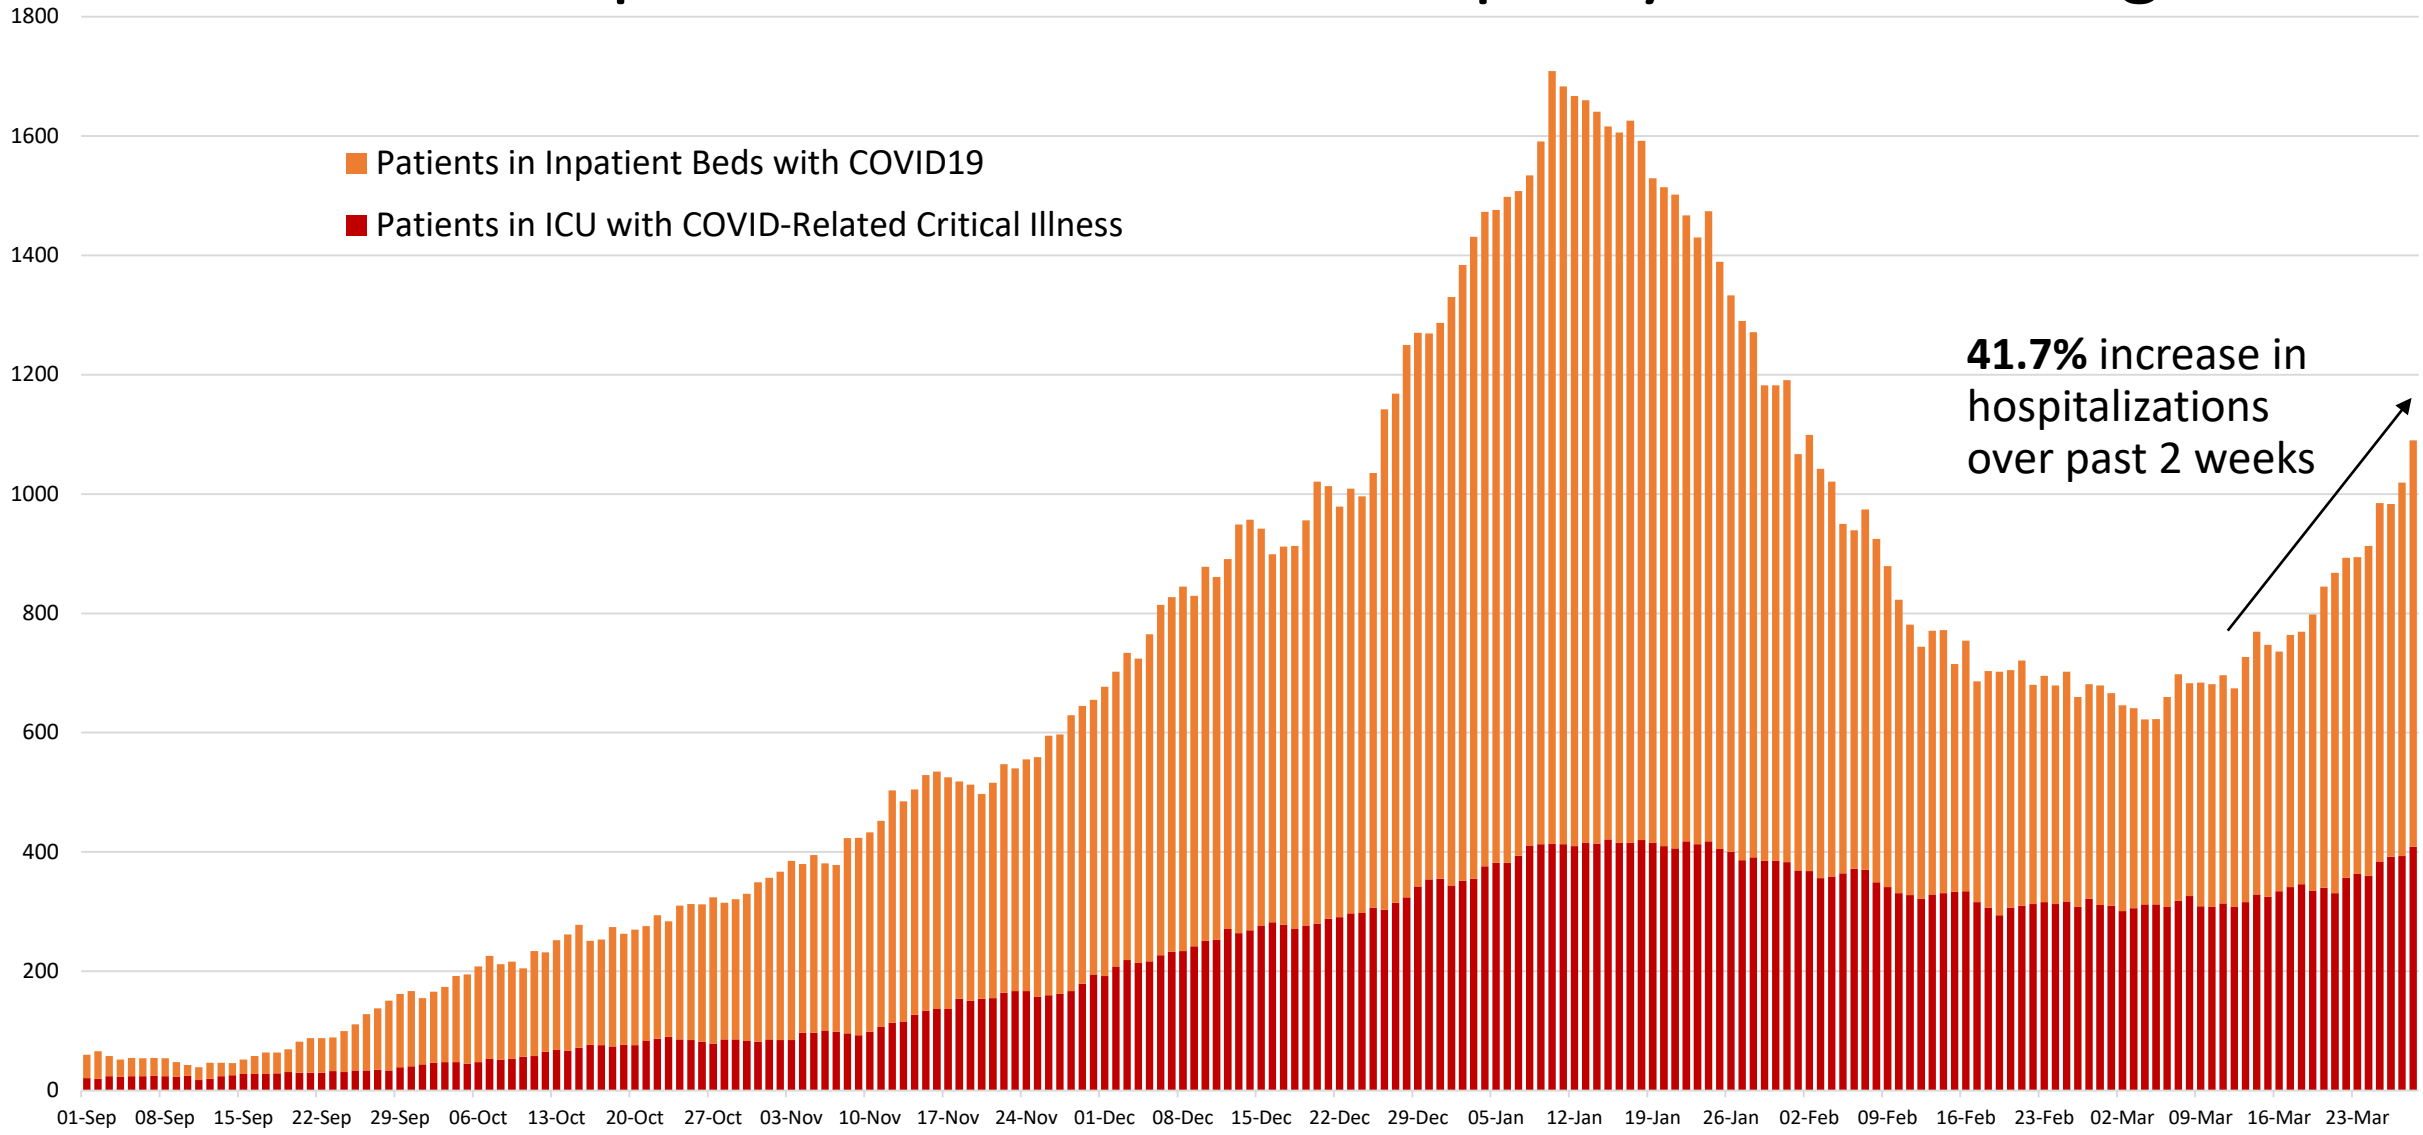
Vaccine assumptions:

- 70% effective in preventing infection
- Administered at constant rate
- Administered randomly to population



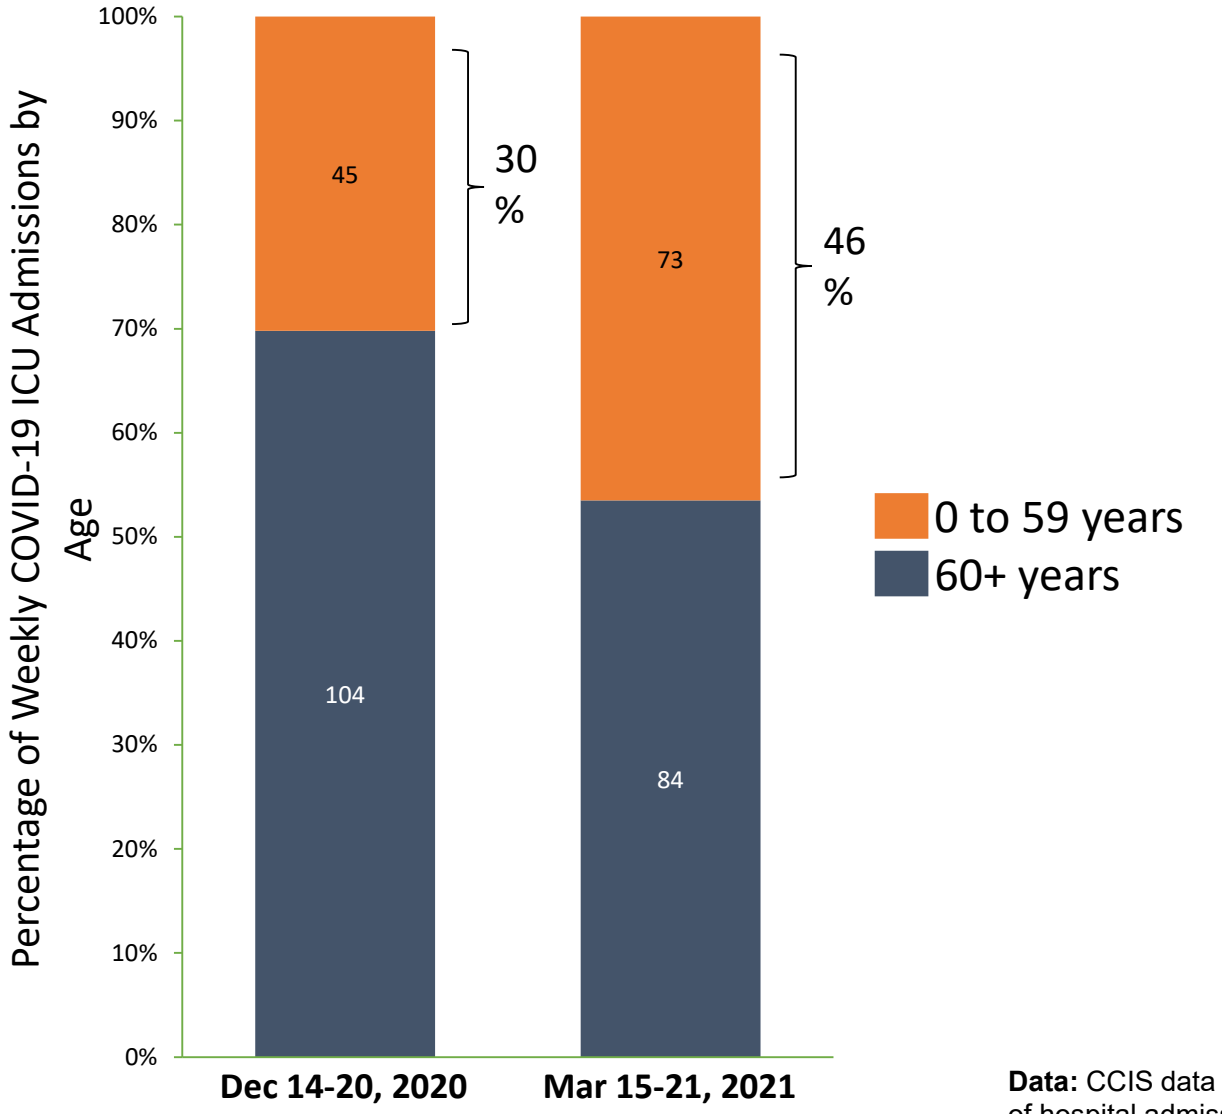
Predictions informed by modeling from COVID-19 ModCollab, Fields Institute, McMasterU, PHO, YorkU
Data (Observed Cases): covid-19.ontario.ca

COVID-19 Hospitalizations and ICU occupancy are increasing



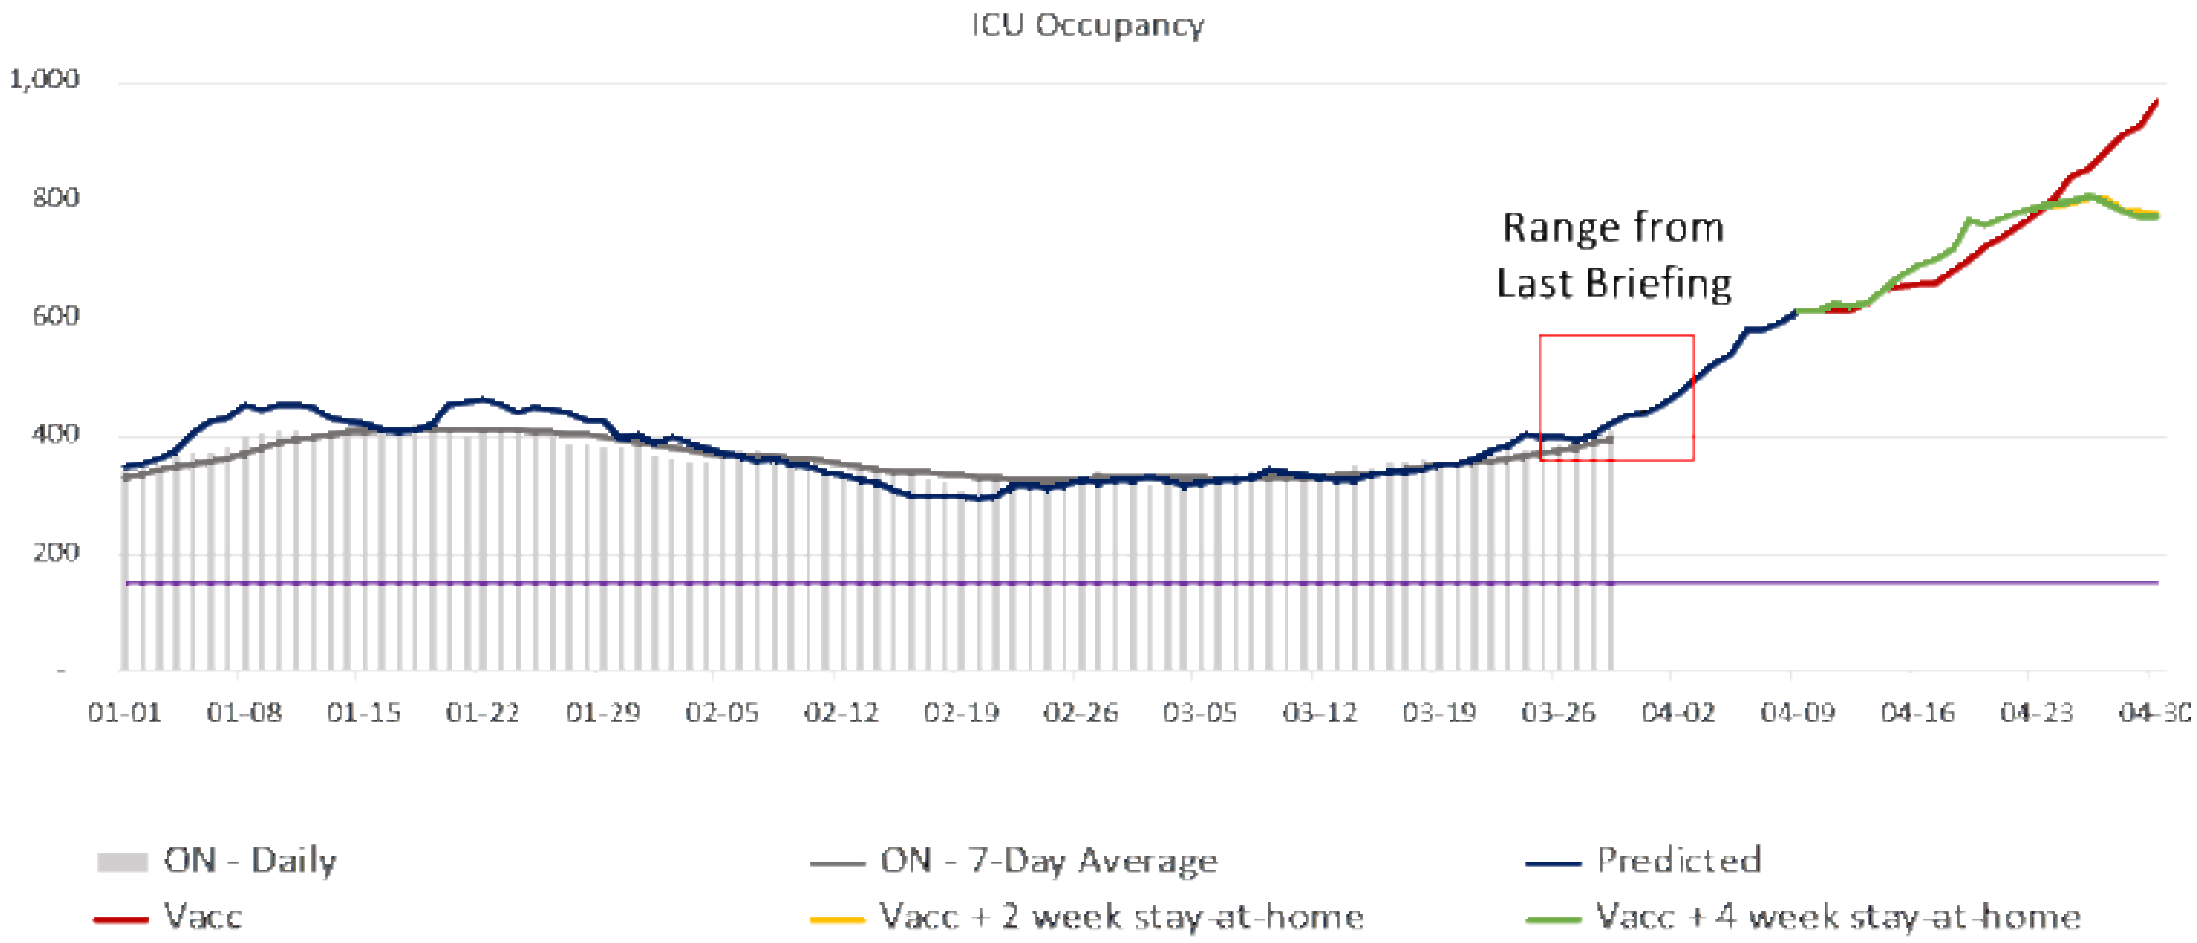
Data Sources: MOH COVID Census and Critical Care Information System

COVID-19 patients admitted to ICU continue to get younger



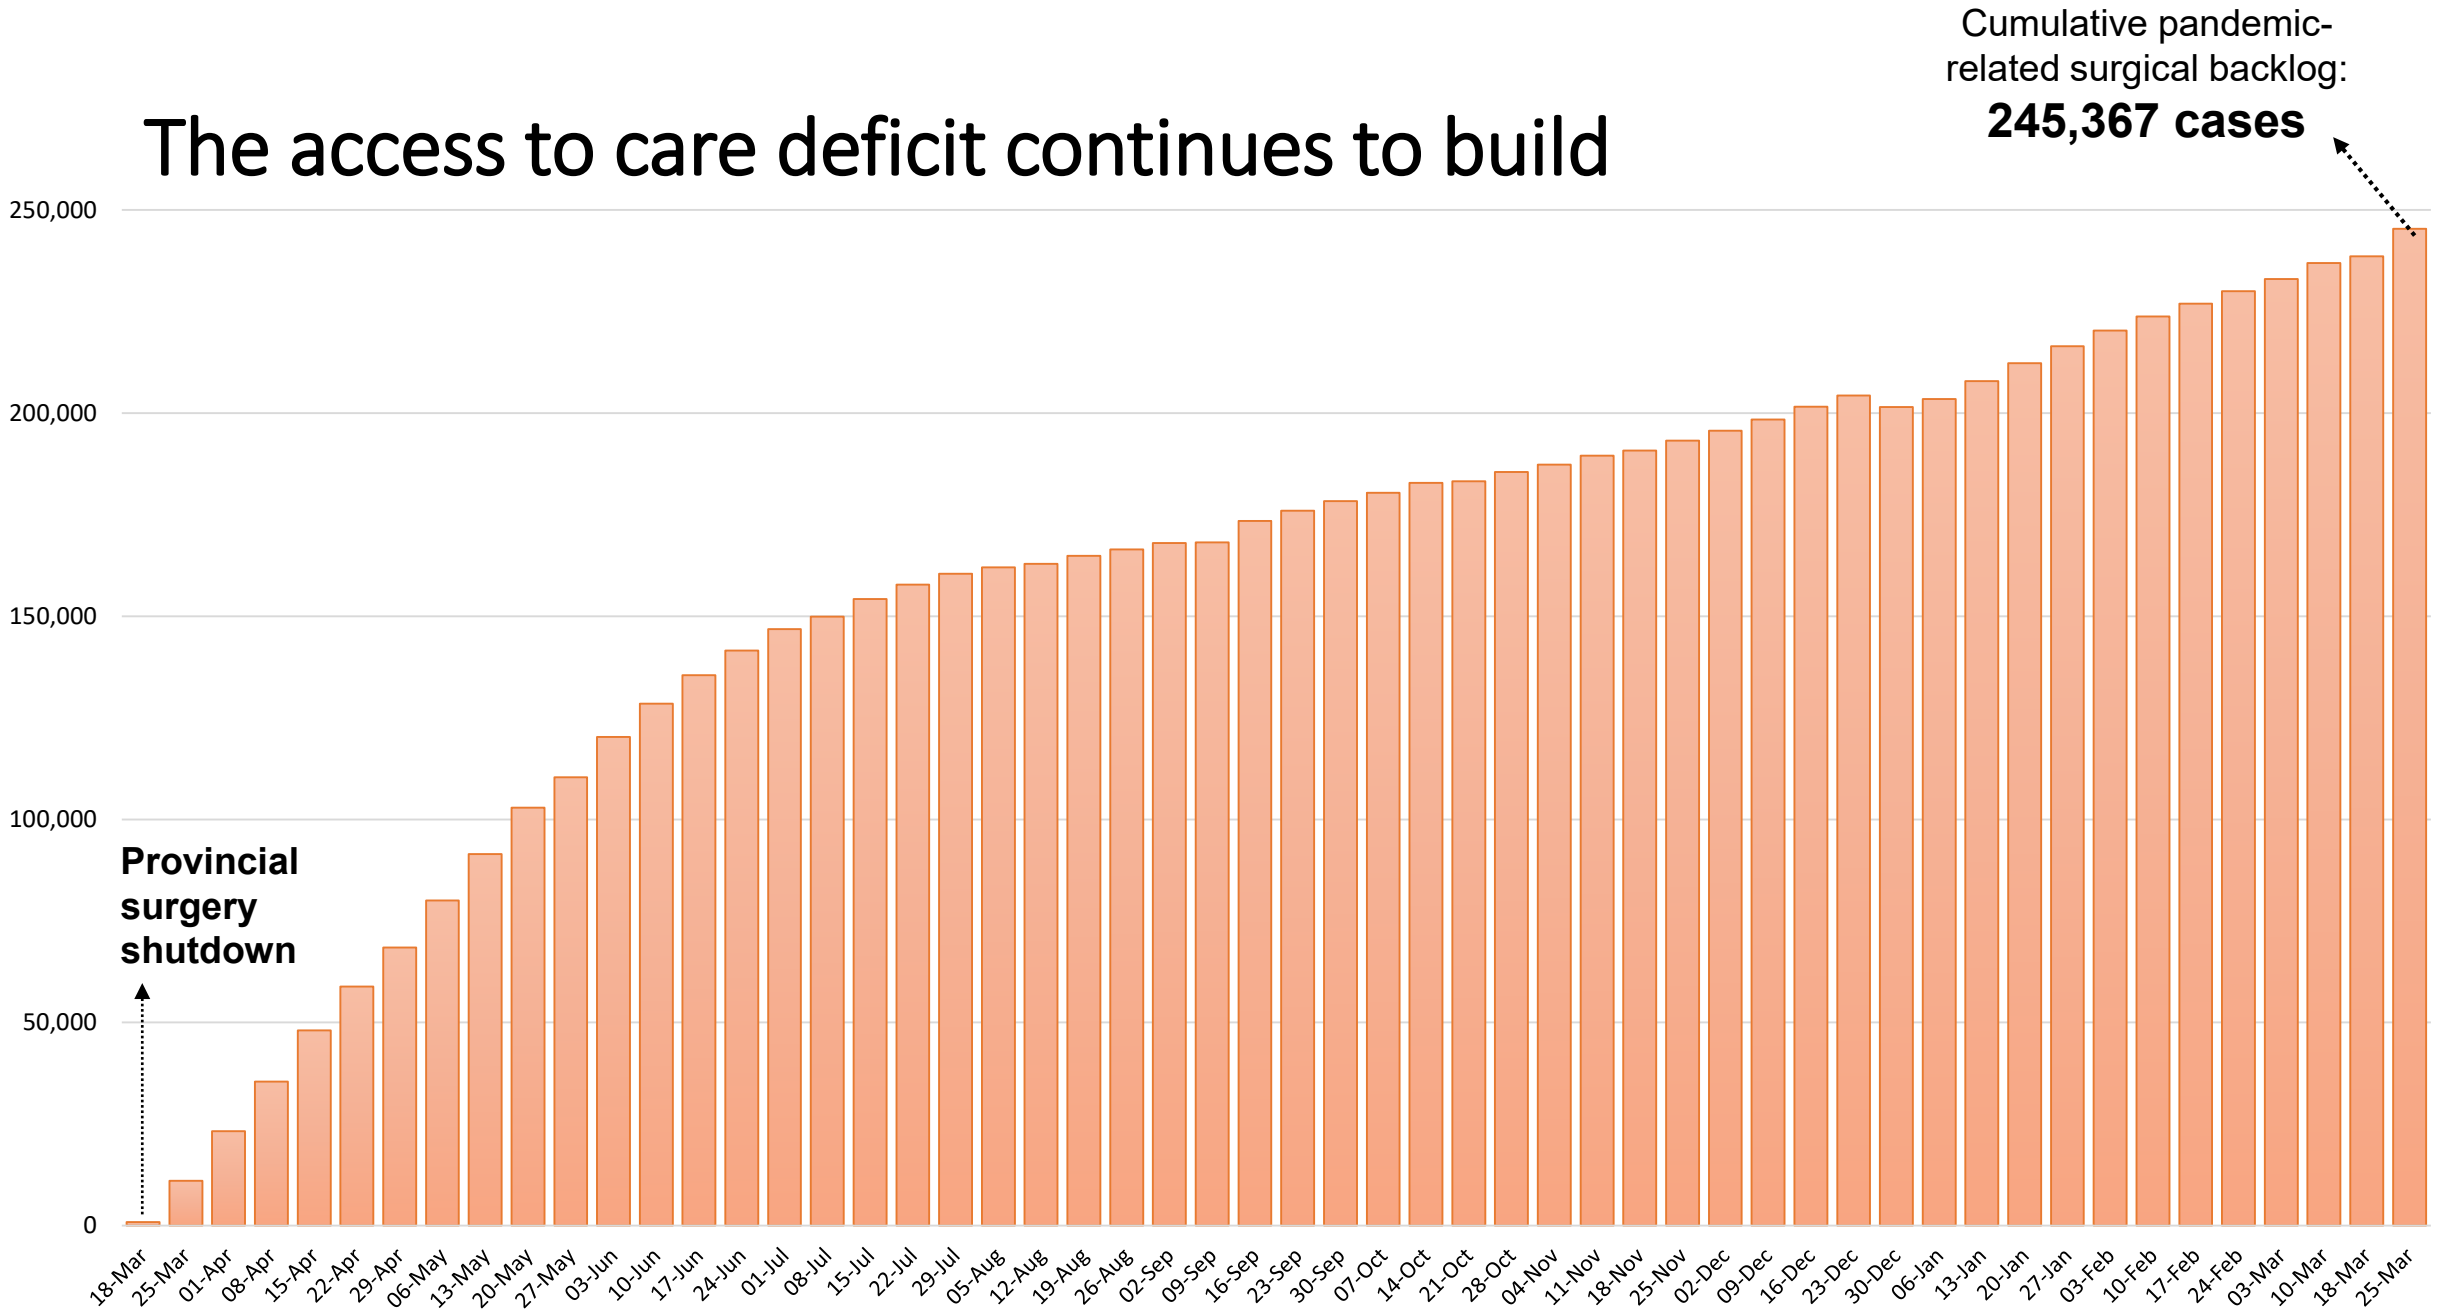
Data: CCIS data up to March 28. Based on date of hospital admission

As with cases, ICU projections depend entirely on system-level public health measures



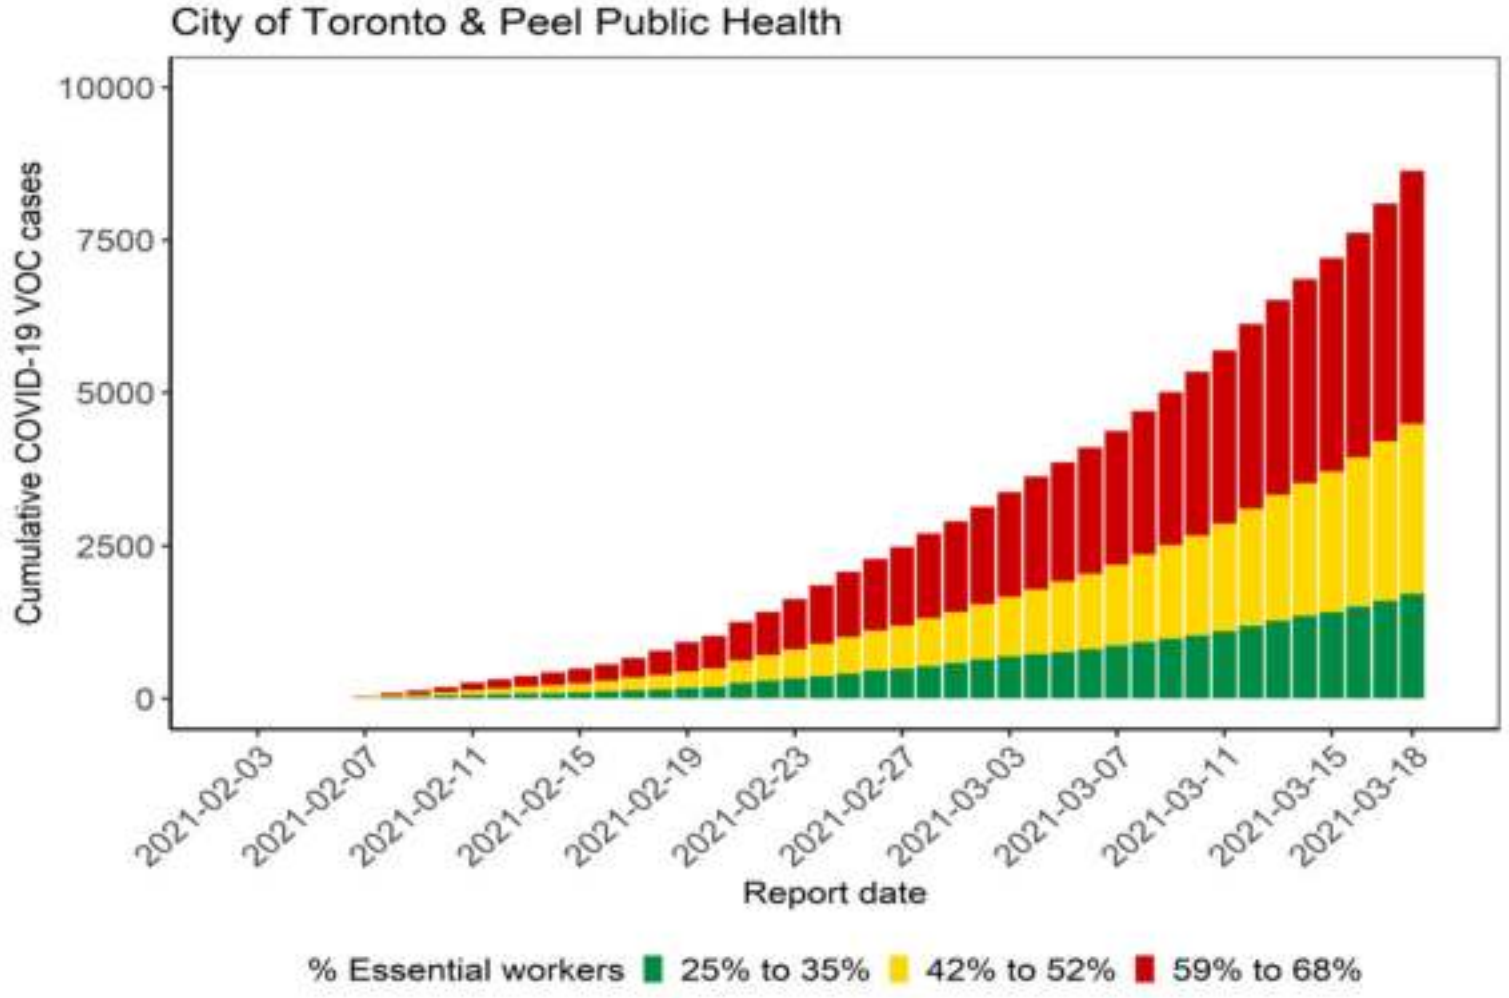
Predictions: COVID-19 ModCollab.
Data (Observed ICU Occupancy): CCSO

The access to care deficit continues to build



Data Source: Wait Times Information System. Backlog estimated based on comparison of 2020/21 with 2019/20 surgical volumes

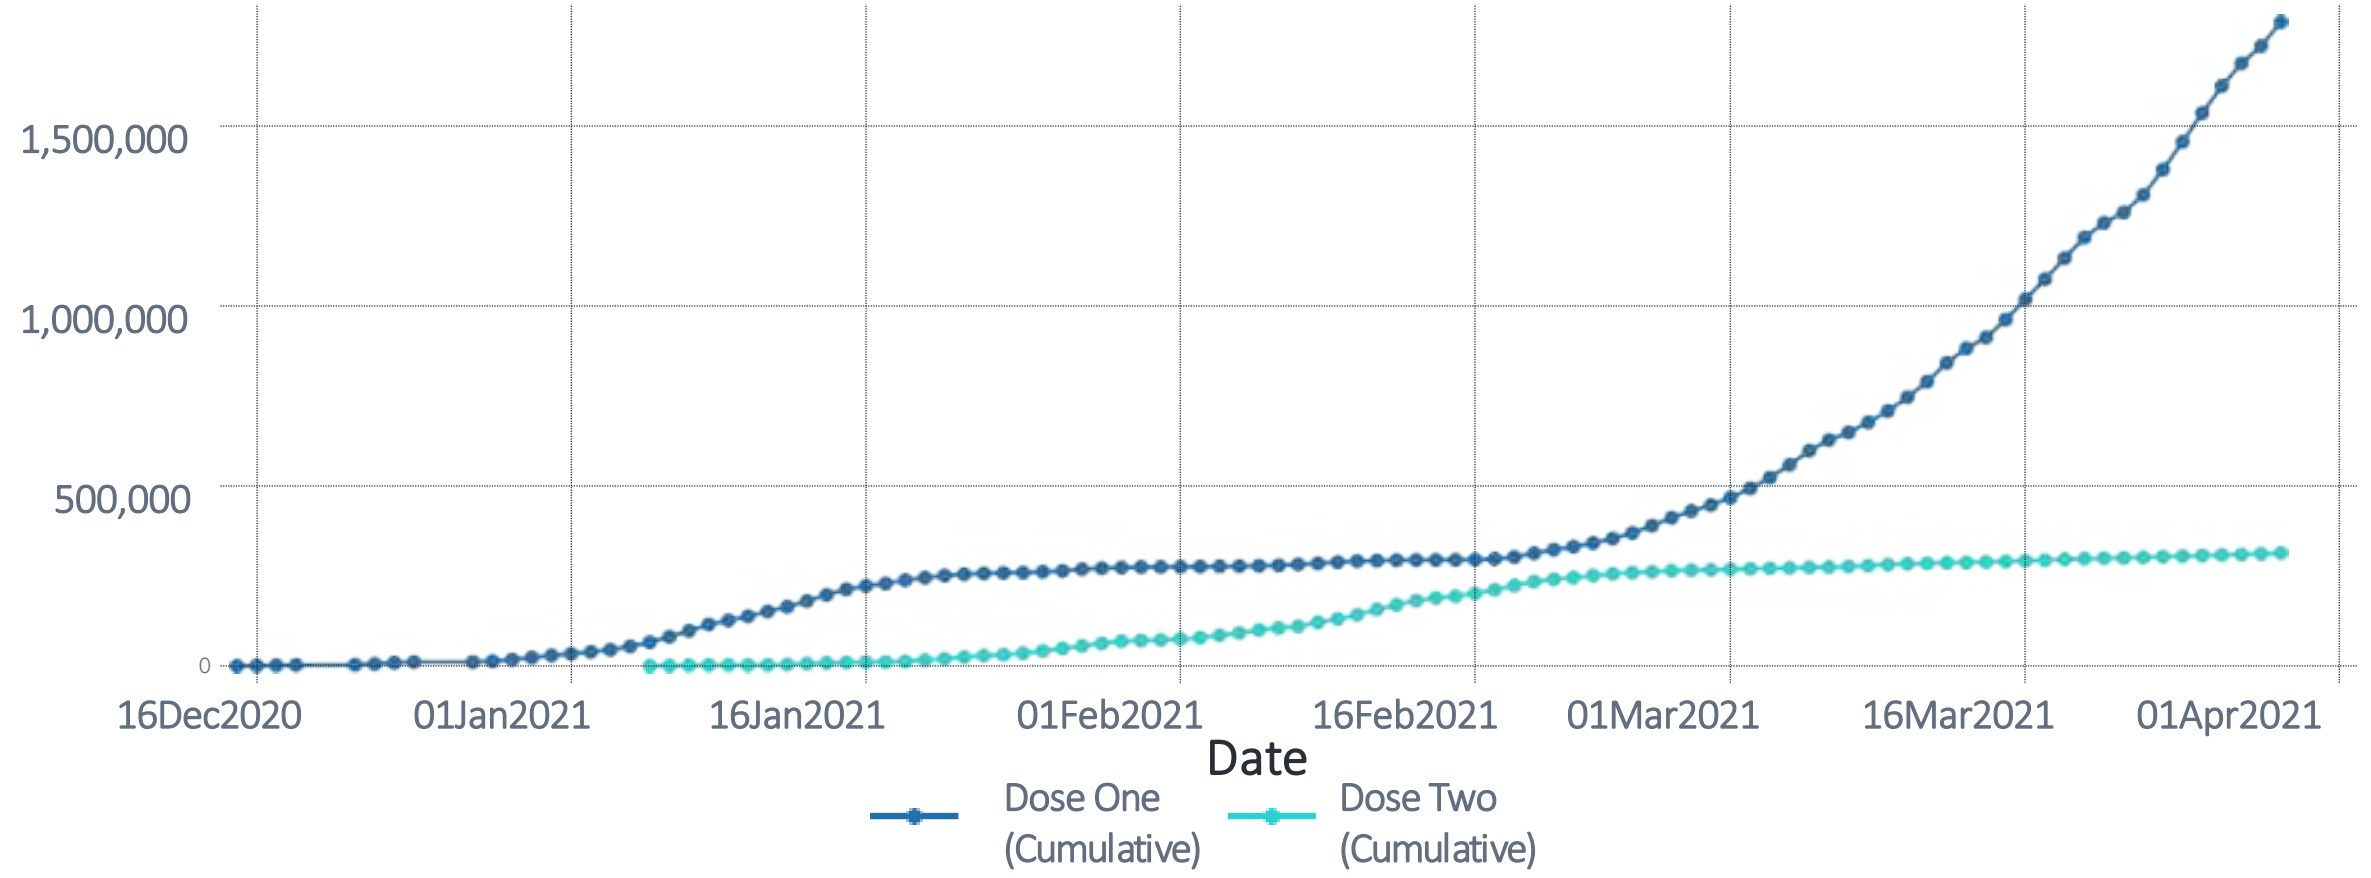
Essential workers are keeping things moving and bearing the brunt of the pandemic. Vaccination and control of workplace outbreaks will be critical.



Source: Chagla Z, Ma H, Sander B, Baral S, Mishra S. (2021). Characterizing the disproportionate burden of SARS-CoV-2 variants of concern among essential workers in the Greater Toronto Area, Canada. https://www.medrxiv.org/content/10.1101/2021.03.22.21254127v1.full.pdf

First dose vaccine coverage expanding but remains incomplete

80 years and older - 17% incomplete; 75-79 years – 40% incomplete; 70-74 years – 72% incomplete



Dose 1 Administered was determined based on the first Time Given for each client.
Dose 2 Administered was determined based on the last Time Given for each client where there is more than 1 dose administered

Vaccination is not reaching the highest risk populations

Figure excludes long-term care vaccination

	Neighbourhood Risk‡ **1** = high incidence of COVID-19 infections → **10** = low incidence of COVID-19 infections										
Age group	1	2	3	4	5	6	7	8	9	10	**Overall**
80+	50%	55%	59%	66%	66%	66%	65%	72%	69%	70%	**64%**
75-79	37%	43%	43%	46%	45%	46%	40%	40%	30%	29%	**39%**
70-74	13%	19%	19%	18%	19%	21%	17%	17%	10%	9%	**16%**
65-69	8%	10%	10%	11%	10%	11%	10%	10%	7%	8%	**9%**
60-64	18%	23%	22%	21%	21%	21%	19%	18%	14%	20%	**20%**
55-59	7%	9%	9%	10%	11%	11%	10%	11%	10%	12%	**10%**
50-54	6%	7%	7%	8%	9%	8%	9%	9%	10%	11%	**8%**
45-49	6%	7%	6%	8%	8%	8%	8%	9%	10%	11%	**8%**
40-44	5%	6%	6%	7%	8%	7%	8%	8%	9%	10%	**7%**
16-39	4%	5%	5%	6%	6%	6%	6%	6%	7%	8%	**6%**
Overall	**8%**	**10%**	**10%**	**11%**	**11%**	**12%**	**11%**	**12%**	**11%**	**13%**	**13%**

School interruptions will have significant impacts on students, families, and society

Economic modeling suggests schooling impacts will have long term economic effects:

- A ~3% drop in lifetime earnings for these cohorts;
- Lost GDP for Canada estimated at 1.6 trillion dollars

Non-COVID health risks include:

- Loneliness & social isolation,
- Loss of structure affecting physical activity, sleep and mental health, and
- Decreased ability to detect neglect or abuse.

All negative impacts are highly inequitable with greater learning loss for students facing greater disadvantage

NEWS RELEASE

Ontario Implements Provincewide Emergency Brake

All 34 Public Health Unit Regions to Move into Shutdown

April 01, 2021
Office of the Premier

TORONTO —The Ontario government, in consultation with the Chief Medical Officer of Health and other health experts, is imposing a provincewide emergency brake as a result of an alarming surge in case numbers and COVID-19 hospitalizations across the province. The provincewide emergency brake will be effective Saturday, April 3, 2021, at 12:01 a.m. and the government intends to keep this in place for at least four weeks.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Dr. David Williams, Chief Medical Officer of Health, and Dr. Adalsteinn (Steini) Brown, Co-Chair of the Ontario COVID-19 Science Advisory Table.

"We are facing a serious situation and drastic measures are required to contain the rapid spread of the virus, especially the new variants of concern," said Premier Ford. "I know pulling the emergency brake will be difficult on many people across the province, but we must try and prevent more people from getting infected and overwhelming our hospitals. Our vaccine rollout is steadily increasing, and I encourage everyone who is eligible to get vaccinated. That is our best protection against this deadly virus."

Ontario's key indicators and latest modelling show that additional measures must be taken. From March 26 to 28, 2021, provincial case rates have increased by 7.7 per cent to 101.1 cases per 100,000 people. Current COVID-19 related ICU admissions are already over the peak of wave two and hospitals in regional hotspots will need to further ramp down scheduled surgeries. COVID-19 related ICU admissions are projected to exceed 650 beds in a few weeks. These increases are being driven by COVID-19 variants, which are transmitted easily and result in a higher risk of death and hospitalization, including in younger populations.

The provincewide emergency brake would put in place time-limited public health and workplace safety measures to help to stop the rapid transmission of COVID-19 variants in communities, protect hospital capacity and save lives. Measures include, but are not limited to:

- Prohibiting indoor organized public events and social gatherings and limiting the capacity for outdoor organized public events or social gatherings to a 5-person maximum, except for gatherings with members of the same household (the people you live with) or gatherings of members of one household and one other person from another household who lives alone.
- Restricting in-person shopping in all retail settings, including a 50 per cent capacity limit for supermarkets, grocery stores, convenience stores, indoor farmers' markets, other stores that primarily sell food and pharmacies, and 25 per cent for all other retail including big box stores, along with other public health and workplace safety measures;
- Prohibiting personal care services;
- Prohibiting indoor and outdoor dining. Restaurants, bars and other food or drink establishments will be permitted to operate by take-out, drive-through, and delivery only;
- Prohibiting the use of facilities for indoor or outdoor sports and recreational fitness (e.g., gyms) with very limited exceptions;
- Requiring day camps to close; and,
- Limiting capacity at weddings, funerals, and religious services, rites or ceremonies to 15 per cent occupancy per room indoors, and to the number of individuals that can maintain two metres of physical distance outdoors. This does not include social gatherings associated with these services such as receptions, which are not permitted indoors and are limited to five people outdoors.

On the advice of the Chief Medical Officer of Health, all Ontarians are asked to limit trips outside the home to necessities such as food, medication, medical appointments, supporting vulnerable community members, or exercising outdoors with members of their household. Employers in all industries should make every effort to allow employees to work from home.

"Ontario, like many other provinces and jurisdictions around the world, is in the third wave of the COVID-19 pandemic and immediate action is required to help turn the tide," said Christine Elliott, Deputy Premier and Minister of Health. "Implementing a provincewide emergency brake was not an easy decision to make and is not one we take lightly. As we continue to vaccinate more Ontarians, the end is in sight, but right now these necessary measures will help to stop the spread of variants in our communities, protect capacity in our health care system, and save lives."

The current *COVID-19 Response Framework: Keeping Ontario Safe and Open*, will be paused when the provincewide emergency brake comes into effect. The impacts of these time-limited measures will be evaluated throughout the next four weeks to determine if it is safe to lift any restrictions or if they need to be extended. With more than $1.6 billion invested to protect against COVID-19, schools remain safe for students and staff. Keeping schools open is critical to the mental health and well-being of Ontario youth. During the emergency shutdown, schools will remain open for in-person learning with strict safety measures in place. The spring break will continue as planned for the week of April 12. In order to support working families, child care will remain open during the shutdown. Child care settings will continue to adhere to stringent health and safety measures so that they remain safe places for children and staff.

"In the last few weeks a significant increase in COVID-19 cases and variants of concern has been observed across Ontario which has put considerable strain on our public health and health care systems," said Dr. David Williams, Chief Medical Officer of Health. "Implementing a provincewide shutdown is needed to bring the third wave of this pandemic under control so that we can save lives, keep our education system open and allow our vaccination program to take hold."

Quick Facts

- Based on the latest modelling data, variants of concern are continuing to grip the province and drive this third wave of the pandemic. Case rates are rising, younger Ontarians are becoming sicker and ICU capacity is at risk of becoming overwhelmed without stronger public health and workplace safety measures in place.
- The 2021 Budget, *Ontario's Action Plan: Protecting People's Health and Our Economy*, brings the government's total investments to protect the economy to $23.3 billion. This includes an estimated $3.4 billion to support approximately 120,000 small businesses across Ontario via two rounds of the Ontario Small Business Support Grant. Applications for the Ontario Small Business Support Grant have been extended for one week through April 7 and all eligible businesses are encouraged to apply.
- Additionally, the new Ontario Tourism and Hospitality Small Business Support Grant will provide an estimated $100 million in one-time payments of $10,000 to $20,000 to eligible small businesses in the tourism and hospitality sector. Businesses required to close or significantly restrict services due to provincial public health measures can continue to apply for property tax and energy cost rebates. Visit Ontario.ca/COVIDsupport for more information on Ontario's supports for businesses.
- To ensure that every person who requires care in a hospital can access a bed, the government has invested more than $5.1 billion to support hospitals since the start of the pandemic, creating more than 3,100 additional hospital beds and 500 critical care and high intensity medicine beds. This includes $1.8 billion in 2021–22 to continue providing care for COVID-19 patients, addressing surgical backlogs and keeping pace with patient needs through its *Ontario's Action Plan: Protecting People's Health and Our Economy.*
- The province continues to deploy rapid testing in workplaces, including up to 300,000 COVID-19 tests per week for asymptomatic staff in key sectors such as manufacturing, warehousing, supply chain, mining, construction and food processing. More than 4.7 million rapid antigen tests have been sent to over 1,150 workplaces, including 89 essential industry sites, under the Provincial Antigen Screening Program.
- The Ontario government continues to implement its High Priority Communities Strategy to provide targeted supports to communities hardest hit by COVID-19. In these communities 1,000 Community Ambassadors have been mobilized, 30 community testing sites have been opened and nearly 36,000 PPE kits have been distributed to community members.
- Get tested if you have COVID-19 symptoms, or if you have been advised of exposure by your local public health unit or through the COVID Alert App. Visit Ontario.ca/covidtest to find the nearest testing location.
- Emergency orders O. Reg. 55/21 (Compliance Orders for Retirement Homes) and O. Reg. 8/21 (Enforcement of COVID-19 Measures) currently in force, under the Emergency Management and Civil Protection Act, have been extended until April 19, 2021, as the province continues to deal with the impacts of COVID-19.

NEWS RELEASE

Ontario Enacts Provincial Emergency and Stay-at-Home Order

Additional measures needed to protect health system capacity and save lives during third wave of COVID-19

April 07, 2021
Office of the Premier

TORONTO — The Ontario government, in consultation with the Chief Medical Officer of Health and other health experts, is immediately declaring a third provincial emergency under s 7.0.1 (1) of the *Emergency Management and Civil Protection Act* (EMPCA). These measures are being taken in response to the rapid increase in COVID-19 transmission, the threat on the province's hospital system capacity, and the increasing risks posed to the public by COVID-19 variants.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Solicitor General Sylvia Jones, and Dr. David Williams, Chief Medical Officer of Health.

"The COVID-19 situation is at a critical stage and we must act quickly and decisively to stay ahead of these deadly new variants," said Premier Ford. "By imposing these strict new measures we will keep people safe while allowing our vaccination program to reach more people, starting with our high risk population and identified hot spots. Although this is difficult, I urge everyone to follow these public health measures and together we will defeat this deadly virus."

Case rates, hospitalizations, and ICU occupancy are increasing rapidly, threatening to overwhelm the health care system. The number of COVID-19 hospitalizations in the province have increased by 28.2 per cent between the period of March 28 and April 5, 2021. In addition, between March 28 and April 5, 2021, Ontario has seen the number of COVID-19 patients in intensive care escalate by 25 per cent. While every action possible is being taken to increase capacity and continue daily surgeries and procedures, the province is reaching a tipping point.

Effective Thursday, April 8, 2021 at 12:01 a.m., the government is issuing a province-wide Stay-at-Home order requiring everyone to remain at home except for essential purposes, such as going to the grocery store or pharmacy, accessing health care services (including getting vaccinated), for outdoor exercise , or for work that cannot be done remotely. As Ontario's health care capacity is threatened, the Stay-at-Home order, and other new and existing public health and workplace safety measures will work to preserve public health system capacity, safeguard vulnerable populations, allow for progress to be made with vaccinations and save lives.

Retail

In addition, the province is also strengthening public health and workplace safety measures for non-essential retail under the provincewide emergency brake. Measures include, but are not limited to:

- Limiting the majority of non-essential retailers to only operate for curbside pick-up and delivery, via appointment, between the hours of 7 a.m. and 8 p.m., with delivery of goods to patrons permitted between 6:00 am and 9:00 pm, and other restrictions;
- Restricting access to shopping malls to limited specified purposes, including access for curbside pick-up and delivery, via appointment, with one single designated location inside the shopping mall, and any number of designated locations outside the shopping mall, along with other restrictions;
- Restricting discount and big box stores in-person retail sales to grocery items, pet care supplies, household cleaning supplies, pharmaceutical items, health care items, and personal care items only;
- Permitting the following stores to operate for in-person retail by appointment only and subject to a 25 per cent capacity limit and restricting allowable hours of operation to between 7 a.m. and 8 p.m. with the delivery of goods to patrons permitted between 6 a.m. and 9 p.m.:
    - Safety supply stores;
    - Businesses that primarily sell, rent or repair assistive devices, aids or supplies, mobility devices, aids or supplies or medical devices, aids or supplies;

    - Rental and leasing services including automobile, commercial and light industrial machinery and equipment rental;
    - Optical stores that sell prescription eyewear to the public;
    - Businesses that sell motor vehicles, boats and other watercraft;
    - Vehicle and equipment repair and essential maintenance and vehicle and equipment rental services; and
    - Retail stores operated by a telecommunications provider or service, which may only permit members of the public to enter the premises to purchase a cellphone or for repairs or technical support.
- Permitting outdoor garden centres and plant nurseries, and indoor greenhouses that engage in sales to the public, to operate with a 25 per cent capacity limit and a restriction on hours of operation to between 7 a.m. and 8 p.m.

These additional and strengthened public health and workplace safety measures will be in effect as of Thursday, April 8, 2021 at 12:01 a.m.

Education

Keeping schools and child care open is critical to the mental health and well-being of Ontario children and youth. Schools and child care will remain open for in-person care and learning in public health regions where it is permitted, with strict safety measures in place.

In addition, beginning next week, education workers who provide direct support to students with special education needs across the province, and all education workers in select hot spot areas, will be eligible to register for vaccination. Vaccinations will commence during the April break starting with priority neighborhoods in Toronto and Peel, then rolling out to priority neighborhoods in other hot spot regions, including York, Ottawa, Hamilton, Halton and Durham. This will be followed by a rollout across the province as supply allows.

"While our government took decisive action by implementing the provincewide emergency brake, more needs to be done to protect against the threats to our health system resources and the continued health and safety of individuals and families across the province," said Christine Elliott, Deputy Premier and Minister of Health. "By further strengthening public health and workplace safety measures, we can work to reduce transmission of the virus while we work to rollout Phase 2 of our vaccine distribution plan, and put more needles in the arms of Ontarians."

"The rapid and increasing spread of COVID-19 and the variants of concern pose significant threats to our health care system and the well-being of Ontarians, requiring immediate and decisive action," said Solicitor General Sylvia Jones. "The declaration of a third provincial emergency is necessary to provide the government with the tools needed to help protect the public, reduce the spread of the virus and save lives."

Vaccinations

As part of Phase Two of its COVID-19 vaccine distribution plan, people living in regions with the highest rates of transmission will be prioritized to receive a vaccine, starting with the most at-risk in the Peel and Toronto public health regions. This initiative will be expanded to additional "hot spot" regions based on established patterns of transmission, severe illness, and mortality.

To support this expanded vaccination effort, mobile teams are being organized to administer vaccines in high-risk congregate settings, residential buildings, faith-based locations, and locations occupied by large employers in hot spot neighbourhoods to individuals aged 18 or over. Pop-up clinics will also be set-up in highly impacted neighborhoods, including at faith-based locations and community centres in those hot spots, in collaboration with public health units and community organizations within those communities. The province will provide additional resources to support these mobile and pop-up clinics in the hardest-hit neighbourhoods.

The government will also extend booking for COVID-19 vaccination appointments to more age groups through its provincial booking system, for public health regions with highly impacted neighbourhoods, on Friday, April 9, 2021. Booking eligibility will be extended to include individuals aged 50 and over for COVID-19 vaccination appointments at mass immunization clinics in high-risk areas as identified by postal code, using the provincial booking system.

Workplace Inspections

Health and safety inspectors and provincial offenses officers will increase inspections and enforcement at essential businesses in regional hot zones to continue protecting essential workers while on the job. There have been 19,500 COVID-related workplace inspections and investigations across the province since the beginning of 2021. During those visits, over 450 COVID-19 related tickets have been issued and OHS inspectors have issued over 14,446 OHS orders and stopped unsafe work related to COVID-19 a total of 24 times.

Rapid Testing

Rapid testing continues to be deployed in workplaces for asymptomatic staff in key sectors such as manufacturing, warehousing, supply chain, mining, construction and food processing. Approximately 5.4 million rapid antigen tests have been sent to over 1,150 workplaces, including 100 essential industry sites, under the Provincial Antigen Screening Program. To encourage the use of these tests under the program, additional outreach will occur to employers in regions with highest rates of transmission to increase access to testing, and the process for enrollment in the screening program will be streamlined to allow for quick access to these supports.

"As we continue to see COVID-19 variants of concern drive this third wave of COVID-19, it is evident stronger public health and workplace measures are needed to help interrupt the spread of the virus," said Dr. David Williams, Chief Medical Officer of Health. "By all of us staying at home, while still taking some time to enjoy the outdoors with the people we live with in our local neighbourhoods and maintaining two metres physical distance from others, we can reduce our mobility, minimize transmission, protect our loved ones and our communities, safeguard health system capacity, and save lives."

Quick Facts

- Over the past week, the province's positivity rate is 5.1 per cent, well above the high-alert threshold of 2.5 per cent, and as of April 6, 2021, there has been a total of 2,483 cases with one of the three variants of concern (VoC). The percent of cases in the last week that tested positive for a mutation or VOC was 63.1 per cent.
- On Saturday April 3, 2021, in response to an alarming surge in case numbers and COVID-19 hospitalizations across the province and in consultation with the Chief Medical Officer of Health, the government imposed a provincewide emergency brake, implementing additional time-limited public health and workplace safety measures, including encouraging remote work in all industries to the greatest extent possible and the closure of additional workplaces, further capacity limits on some essential businesses which are able to remain open, and strengthened advice on limiting trips outside of the home for essential reasons.
- On the advice of the Chief Medical Officer of Health, all Ontarians are asked to limit trips outside the home to necessities such as food, medication, medical appointments, supporting vulnerable community members, or exercising outdoors with members of their household in our their communities. Individuals should remain in their local communities and avoid all non-essential travel – even within the province – and to stay home when ill even with mild symptoms. Employers in all industries should make every effort to allow employees to work from home.
- To ensure that every person who requires care in a hospital can access a bed, the government has invested more than $5.1 billion to support hospitals since the start of the pandemic, creating more than 3,100 additional hospital beds and 500 critical care and high intensity medicine beds. This includes $1.8 billion in 2021–22 to continue providing care for COVID-19 patients, addressing surgical backlogs and keeping pace with patient needs through its Ontario's Action Plan: Protecting People's Health and Our Economy.
- The Ontario government continues to implement its High Priority Communities Strategy to provide targeted supports to communities hardest hit by COVID-19. In these communities 1,000 Community Ambassadors have been mobilized, 30 community testing sites have been opened and nearly 36,000 PPE kits have been distributed to community members.
- Get tested if you have COVID-19 symptoms, or if you have been advised of exposure by your local public health unit or through the COVID Alert App. Visit Ontario.ca/covidtest to find the nearest testing location.

NEWS RELEASE

Ontario Moves Schools to Remote Learning Following Spring Break

Continued Rise in COVID-19 Cases Demands Shift to Protect Students and Staff and Slow Community Spread

April 12, 2021
Office of the Premier

TORONTO — The Ontario government, in consultation with the Chief Medical Officer of Health, has made the difficult decision to move elementary and secondary schools to remote learning following the April break. This move has been made in response to the rapid increase in COVID-19 cases, the increasing risks posed to the public by COVID-19 variants, and the massive spike in hospital admissions.

Details were provided today by Premier Doug Ford, Christine Elliott, Deputy Premier and Minister of Health, Stephen Lecce, Minister of Education, and Dr. David Williams, Chief Medical Officer of Health.

"We are seeing a rapidly deteriorating situation with a record number of COVID cases and hospital admissions threatening to overwhelm our health care system," said Premier Ford. "As I have always said we will do whatever it takes to ensure everyone stays safe. By keeping kids home longer after spring break we will limit community transmission, take pressure off our hospitals and allow more time to rollout our COVID-19 vaccine plan."

With appropriate measures in place, schools have been safe places for learning throughout the pandemic, as confirmed by the Chief Medical Officer of Health and local medical officers of health and have demonstrated low rates of in-school transmission. However, increasing rates of community spread pose a threat to the health and safety of school communities. As a result, all publicly funded and private elementary and secondary schools in the province are to move to teacher-led remote learning when students return from the April break on April 19, 2021. Private schools operating in-person this week are to transition to remote learning by April 15, 2021. This action is being taken in support of the Government's broader efforts to limit the spread of COVID-19. Data will be assessed on an ongoing basis and health officials will be consulted to determine when it will be safe to resume in-person learning.

Child care for non-school aged children will remain open, before and after school programs will be closed and free emergency child care for the school-aged children of eligible health care and frontline workers will be provided. To protect the most vulnerable, boards will make provisions for continued in-person support for students with special education needs who require additional support that cannot be accommodated through remote learning.

"This was not a decision we made lightly, as we know how critical schools are to Ontario students. Our priority has always been to keep schools open, however sharply rising community transmission can put our schools and Ontario families at risk," said Minister Lecce. "While Ontario's plan has kept schools safe, as confirmed by the Chief Medical Officer of Health, we are taking decisive and preventative action today to ensure students can safely return to learning in our schools."

Case rates, hospitalizations, and ICU occupancy are increasing rapidly, threatening to overwhelm the health care system. The number of COVID-19 hospitalizations in the province have increased by 22.1 per cent between the period of April 4 and 10, 2021. In addition, during this same period of time, Ontario has seen the number of COVID-19 patients in intensive care increase from 494 to 605.

Since April 8, the province has been under a provincewide Stay-at-Home order, requiring everyone to remain at home except for essential purposes, such as going to the grocery store or pharmacy, accessing health care services (including getting vaccinated), for outdoor exercisewith your household in your home community, or for work that cannot be done remotely. As Ontario's health care capacity is threatened, the Stay-at-Home order, and other new and existing public health and workplace safety measures, will work to preserve public health system capacity, safeguard vulnerable populations, allow for progress to be made with vaccinations and save lives.

With students moving to remote learning, vaccine prioritization of education workers who provide direct support to students with special education needs across the province, and all education workers in select hot spot areas, starting with Peel and Toronto, will continue. Starting today, special education workers across the province and education workers in Peel and Toronto hot spots will be eligible to register for vaccination by calling the provincial vaccine booking line at 1-833-943-3900. More information is available at Ontario.ca/covidvaccine.

It is critically important that as Ontarians receive the vaccine, everyone continues to wear a mask, maintain physical distancing when outside of their immediate household and frequently wash their hands. As well, continue to monitor for symptoms of COVID-19 and get tested if symptoms are present.

"As we continue to see rapid growth in community transmission across the province, it is necessary to take extra precautions and measures to ensure the continued health and safety of students, teachers and their families," said Dr. David Williams, Chief Medical Officer of Health. "As the fight against this third wave of the pandemic continues, everyone must continue following all public health and workplace safety measures and stay at home to prevent further transmission of the virus, so we can once again resume in person learning in our schools."

Quick Facts

- As of April 10, 2021, Ontario currently has 1,646 COVID-19 patients requiring acute care, which includes 605 patients in ICU, with 382 on a ventilator.
- Based on the latest modelling data, cases across the province are continuing to grow and the number of people requiring an intensive care bed is projected to rise to approximately 800 people within the next 10 days.
- Some jurisdictions around the world, including those in Canada have implemented similar time-limited measures to respond to a dramatic resurgence in cases. Based on their experiences, measures of four to six weeks are expected to interrupt transmission of COVID-19 in Ontario.
- Municipalities and local medical officers of health may have additional restrictions or targeted requirements in their region.
- Get tested if you have symptoms compatible with COVID-19, or if you have been advised of exposure by your local public health unit or through the COVID Alert App. Visit Ontario.ca/covidtest to find the nearest testing location.
- Prior to April break, more than 99 per cent of students and staff did not have a current case of COVID-19. Since September, 99.2 per cent of students and 98.6 per cent of staff never reported a COVID-19 case.

Update on COVID-19 Projections

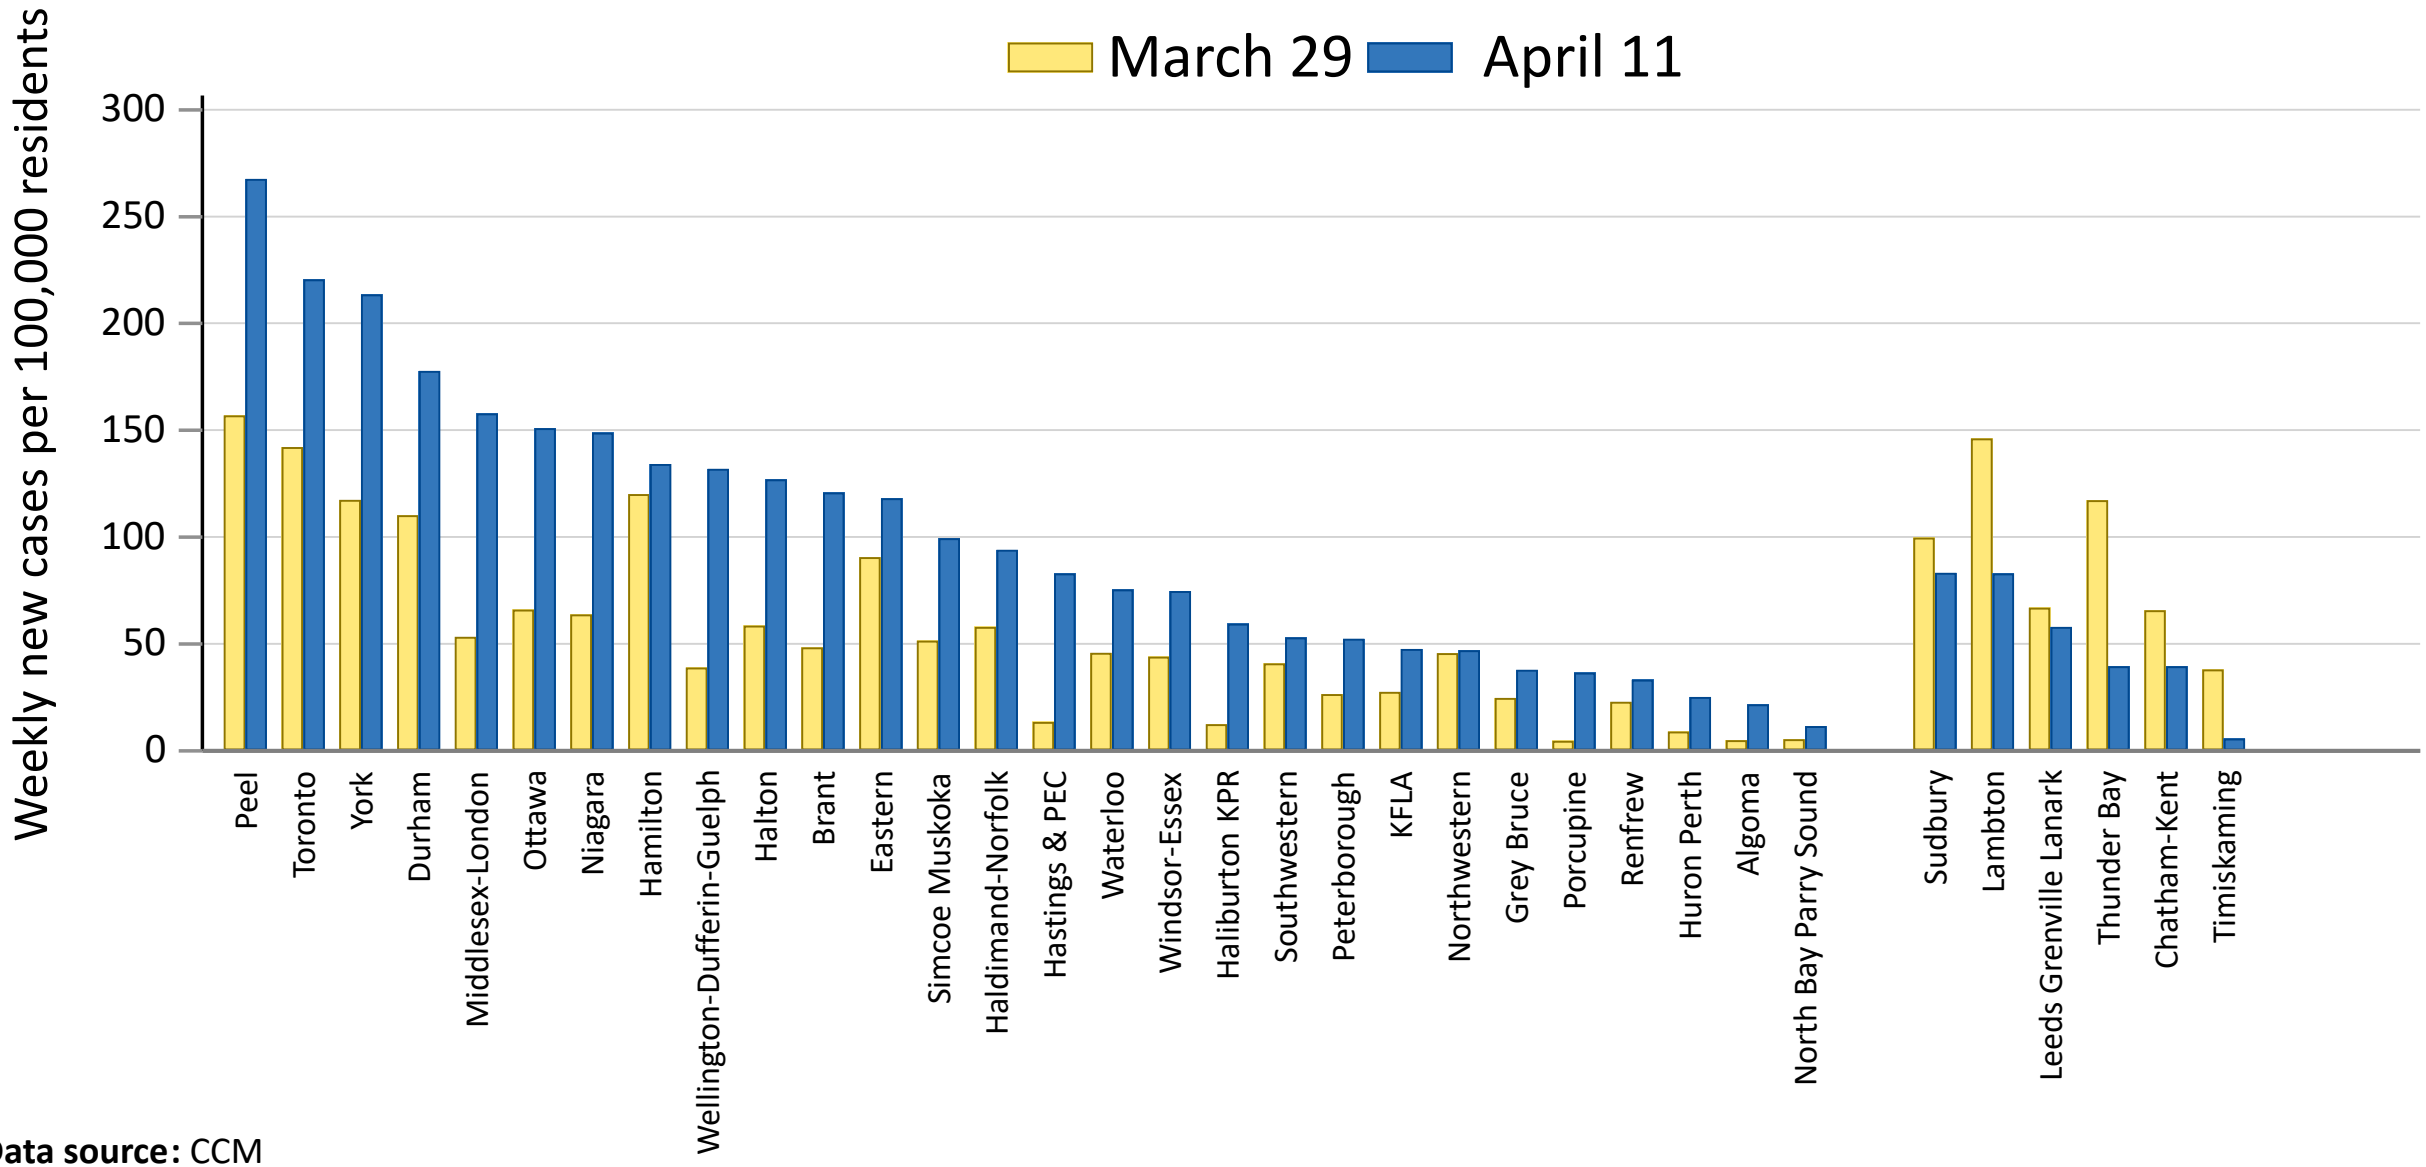
Science Advisory and Modelling Consensus Tables

April 16, 2021

Key Findings

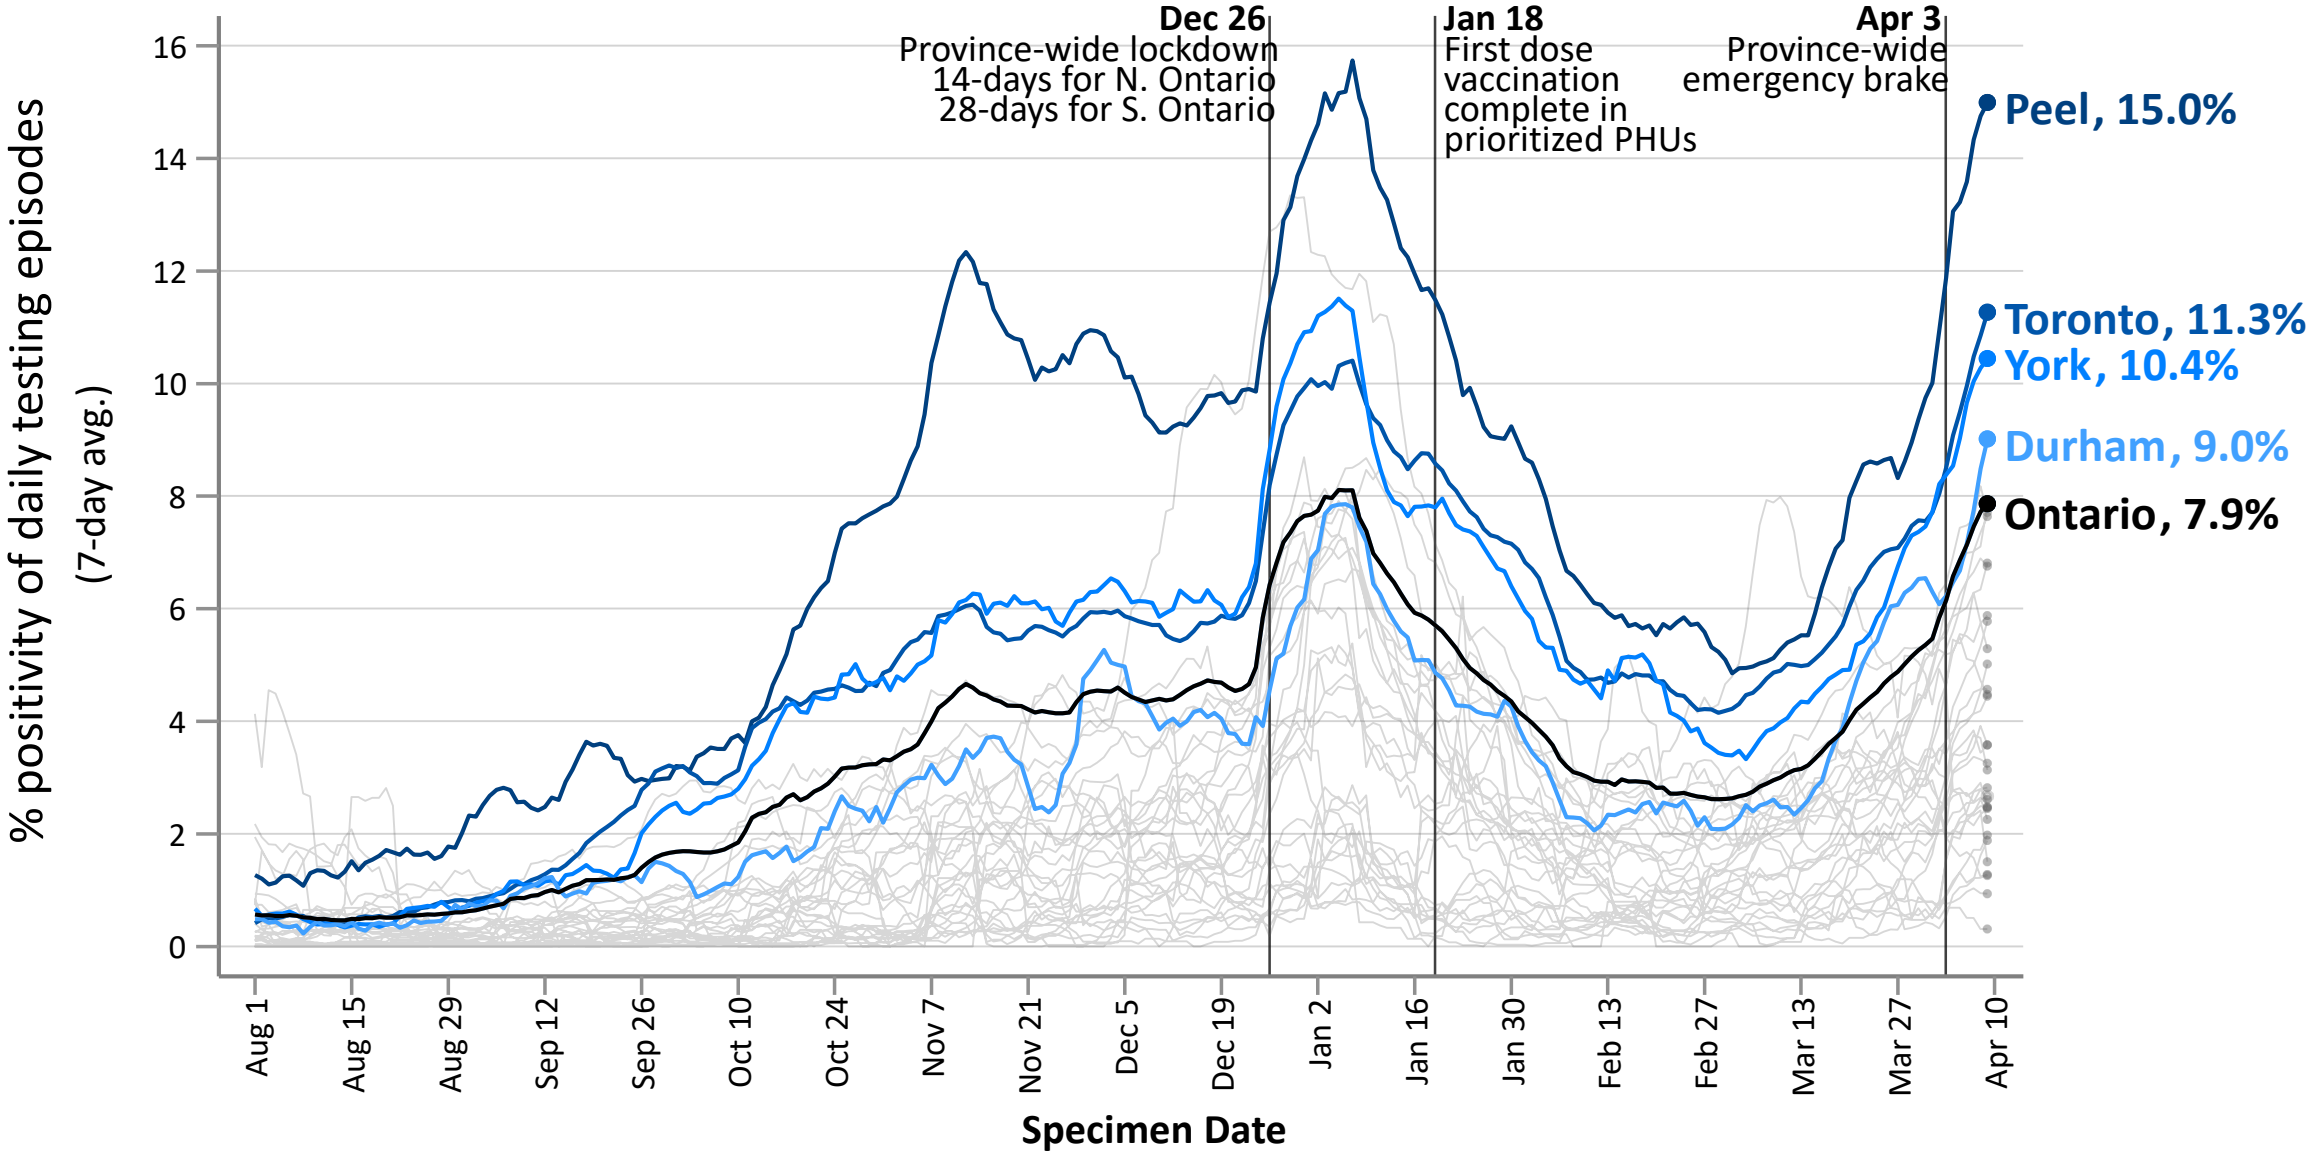
- COVID-19 cases, hospitalizations and ICU occupancy are **at their highest levels since March 2020** and variant cases continue to rise sharply.
- ICU occupancy is **compromising care for all patients.**
- Ontarians can help themselves and others by limiting mobility to truly necessary trips and **always wearing a mask and keeping 6 feet distant** when in contact with anyone outside their household.
- Although improving, vaccination is not reaching people at high-risk fast enough to overcome the level of serious illness in our communities and our hospitals.
- Without stronger system-level measures and immediate support for essential workers and high-risk communities, **high case rates will persist through the summer.**

Cases are **rapidly** increasing in most Public Health Units



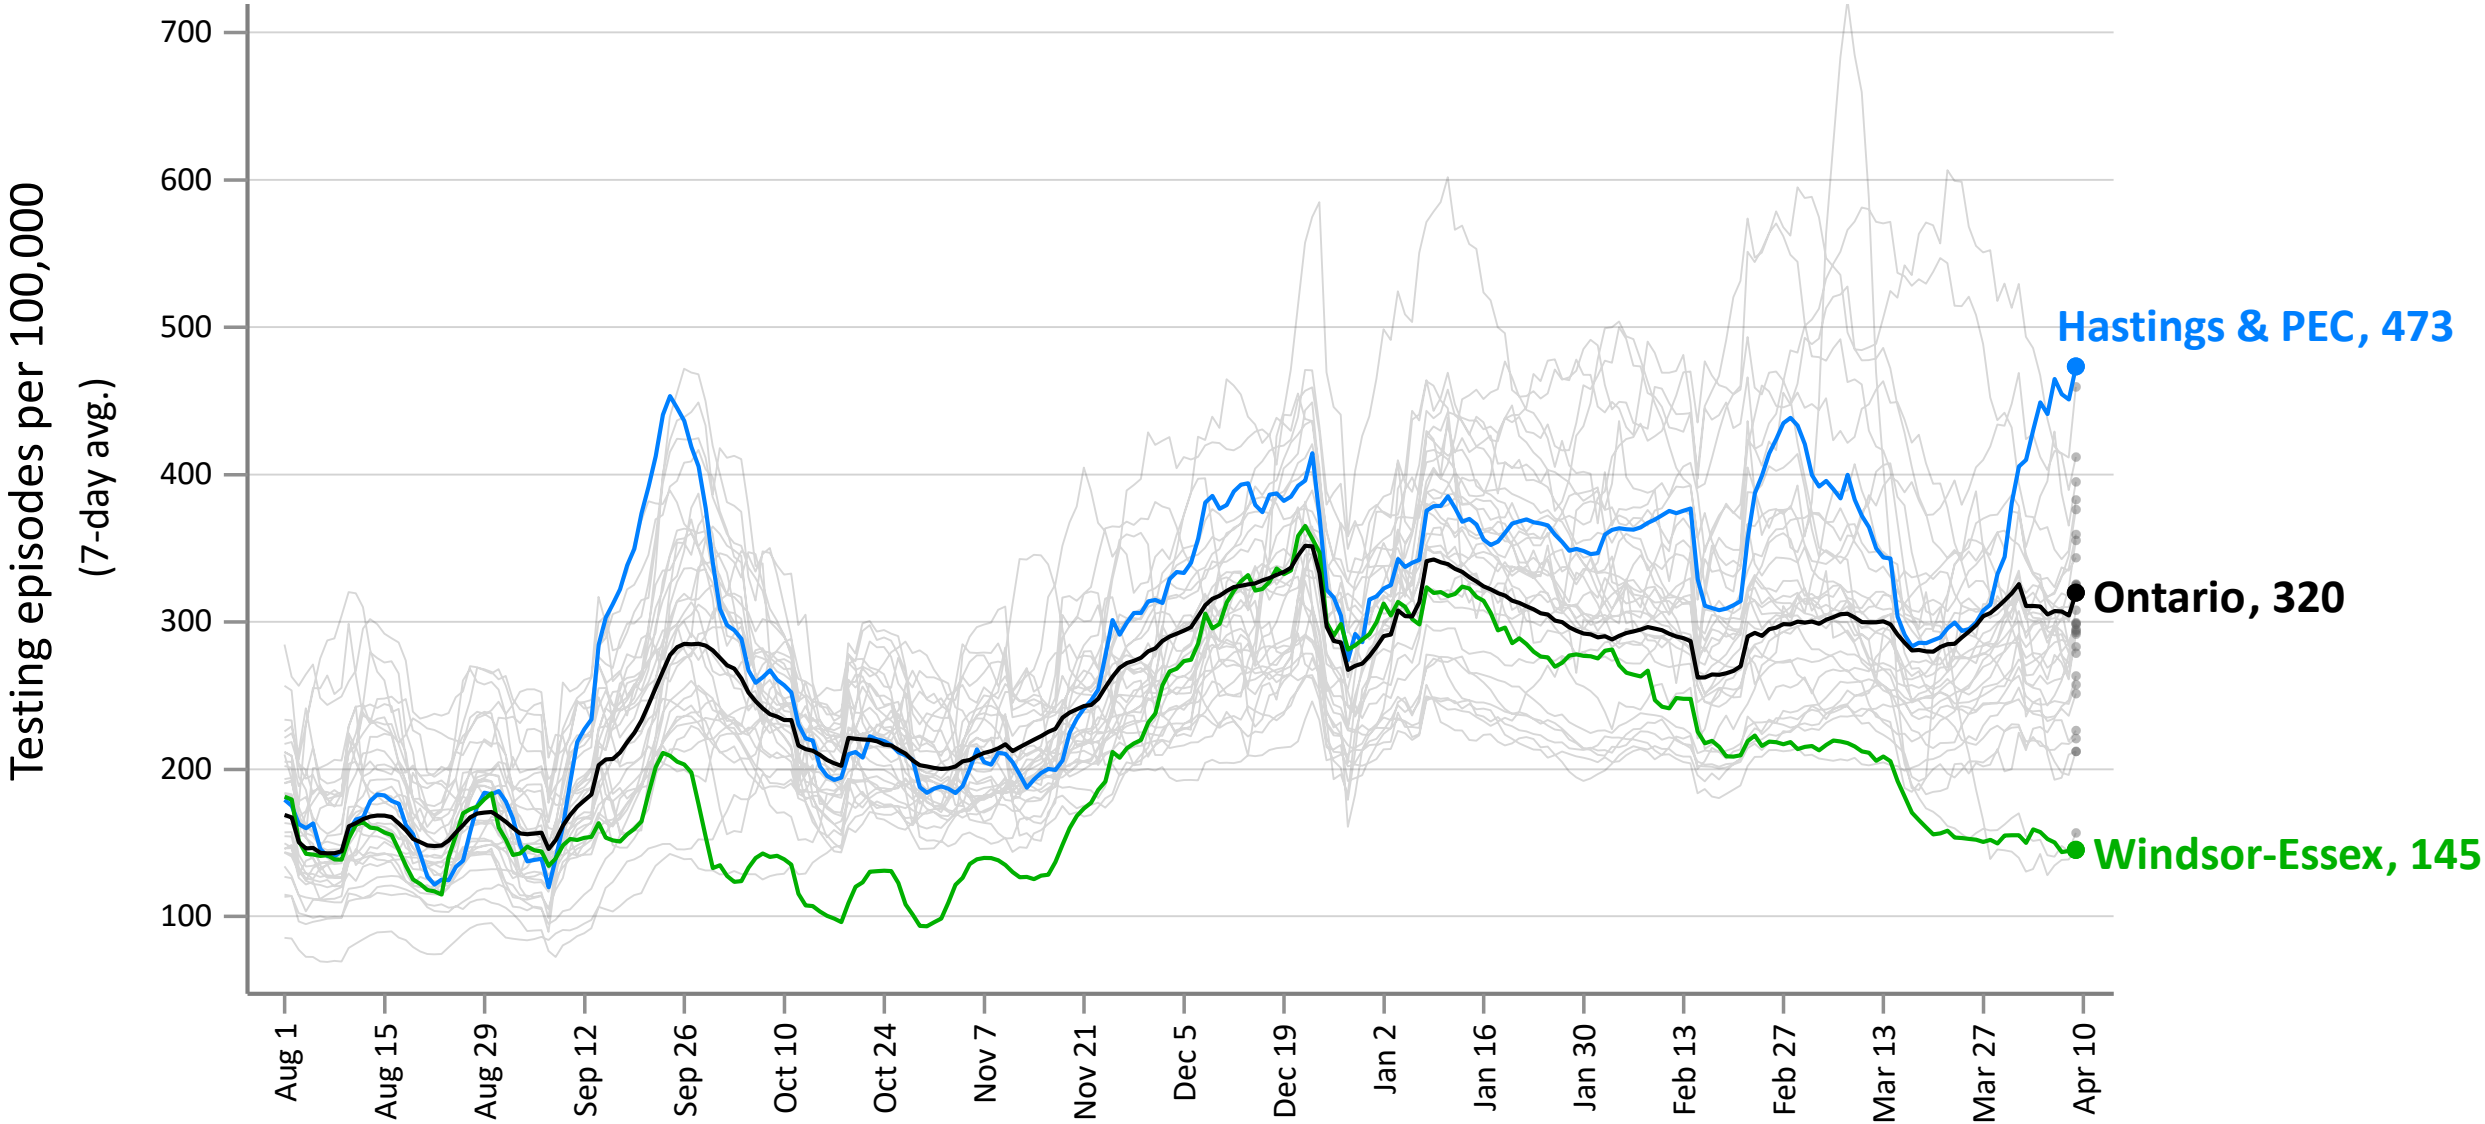
Data source: CCM
Data note: Data for the most recent day have been censored to account for reporting delays

Test positivity rates are increasing across Ontario



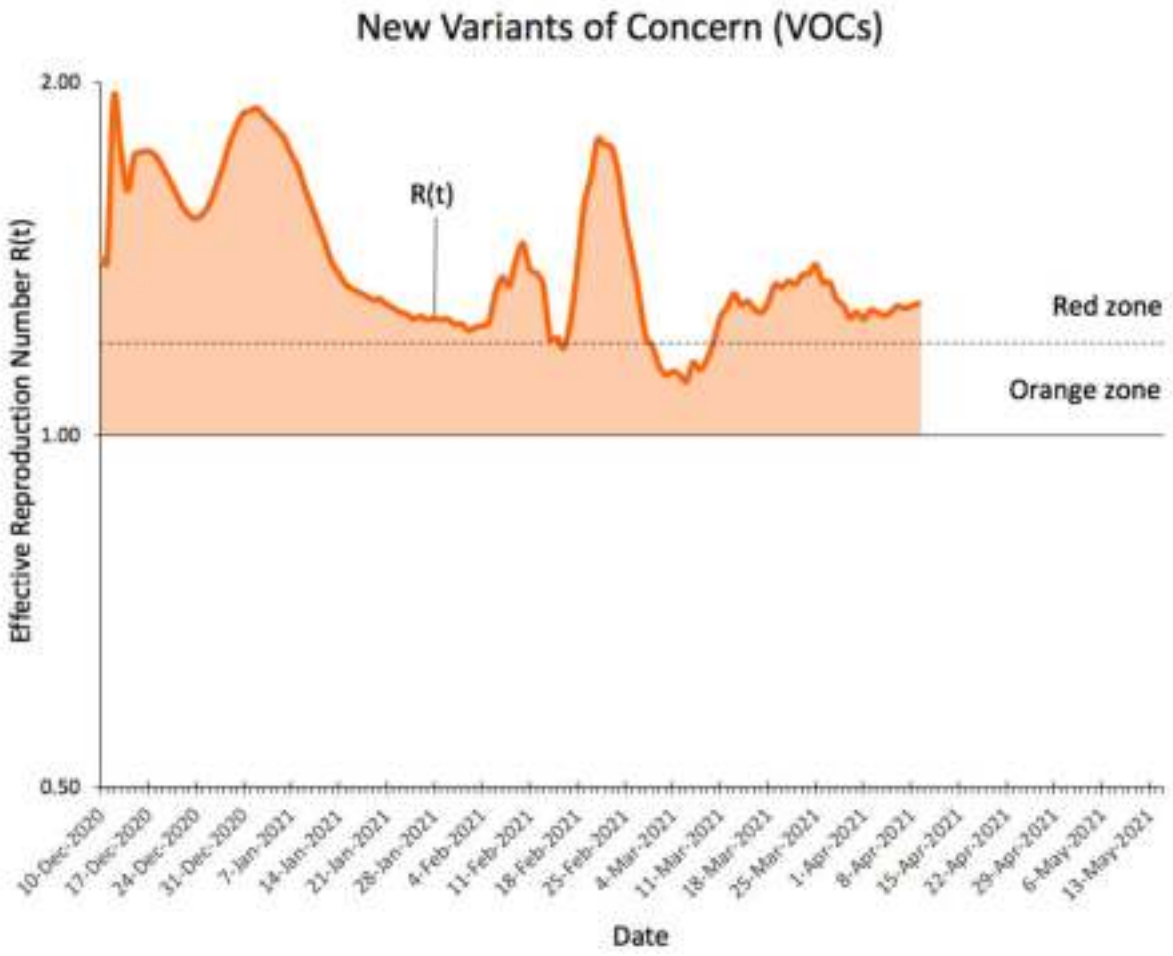
Data source: Ontario Laboratory Information System (OLIS), data up to April 9

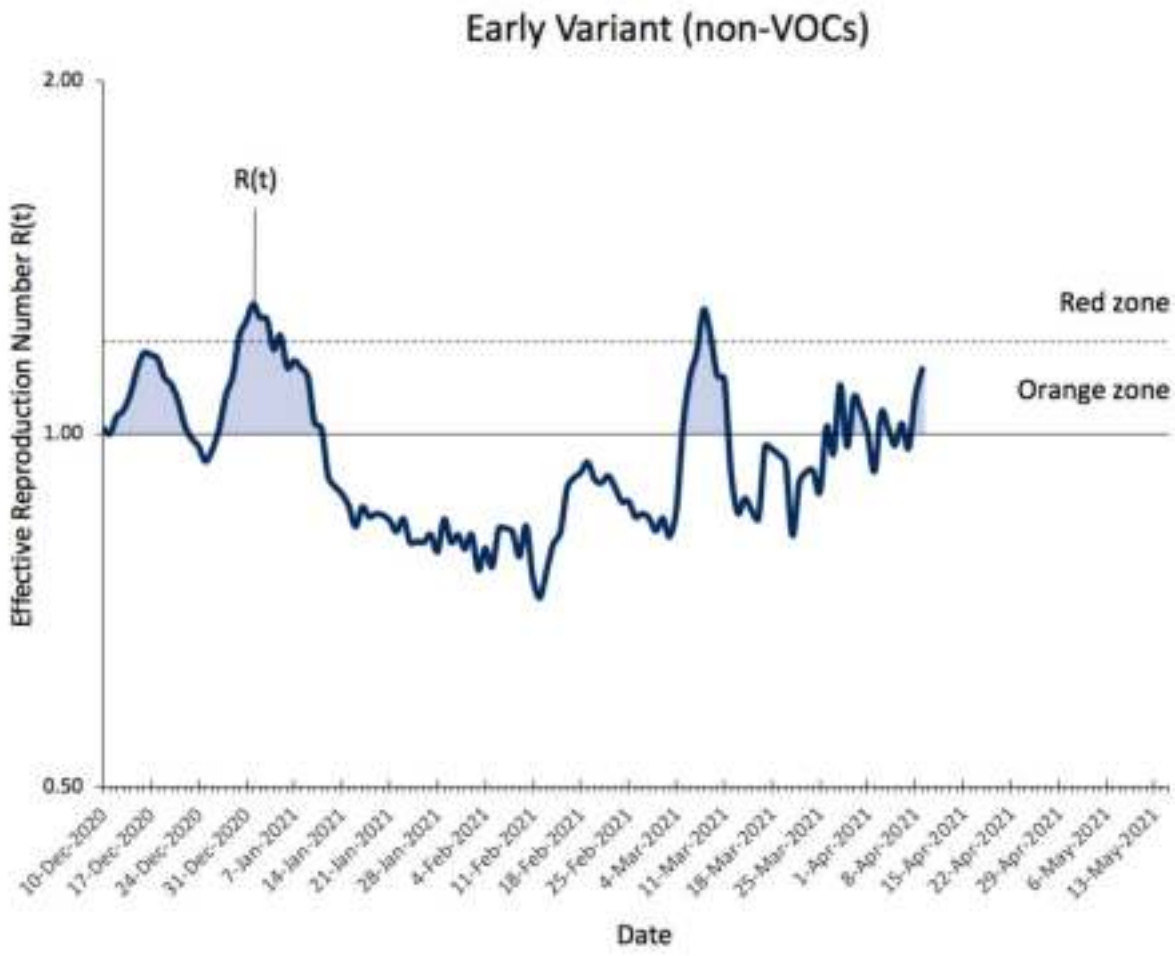
Ontario testing rates are flat – the increase in cases is because there are more cases, not more tests being done



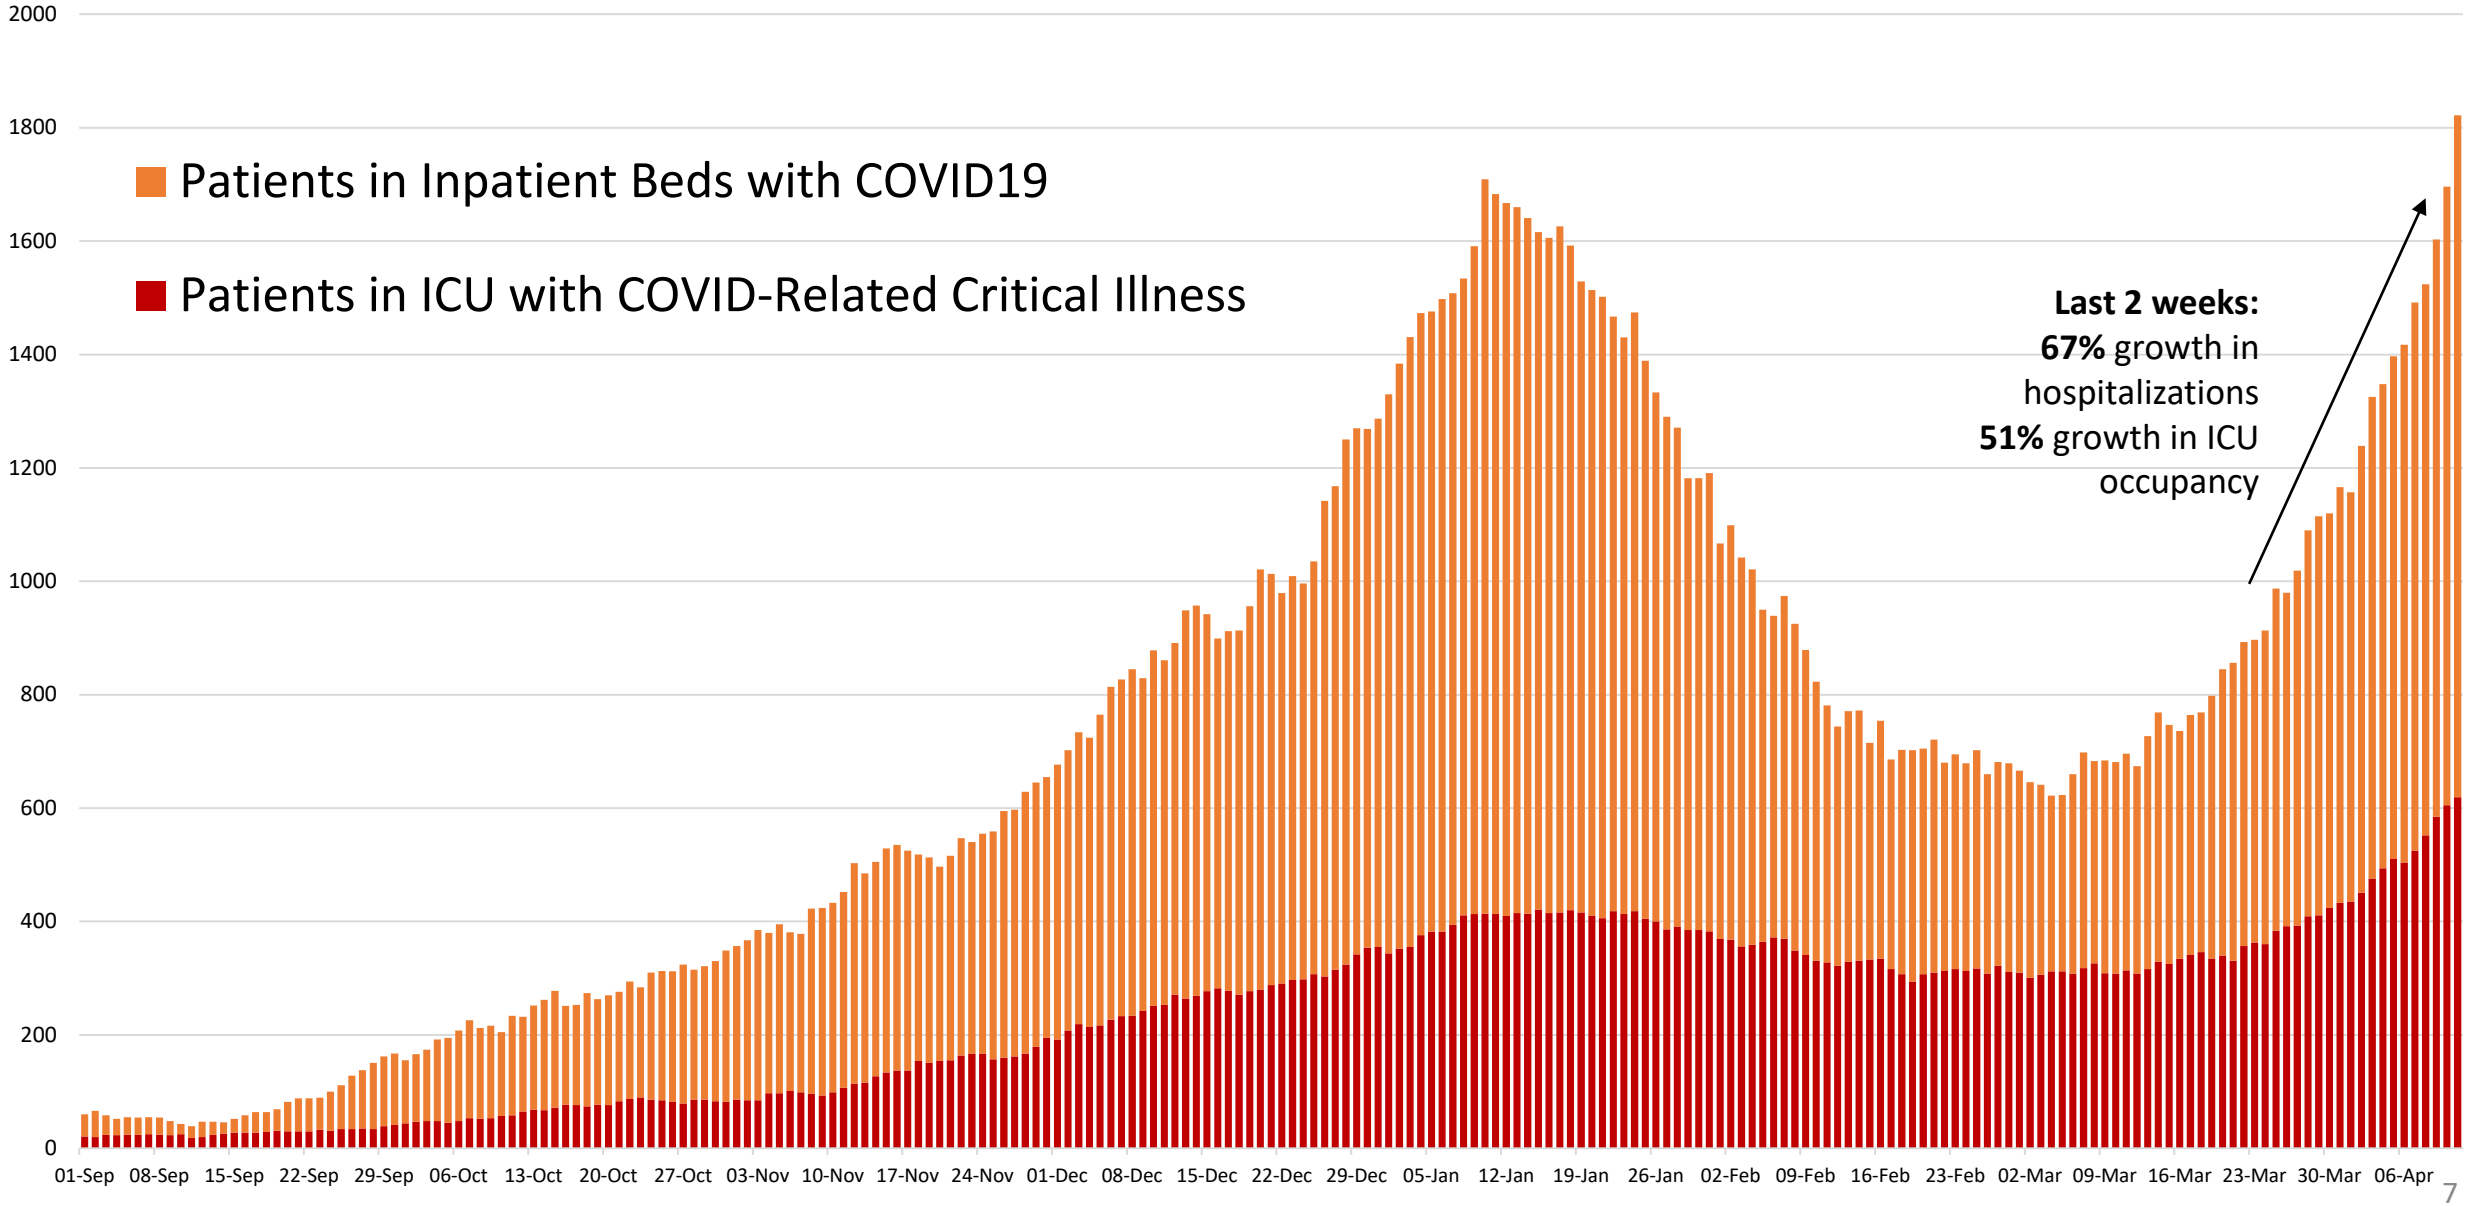
Data source: Ontario Laboratory Information System (OLIS), data up to April 9

The number of variant cases continues to rise and variants now dominate, but even the original strain is rising.





A record number of Ontarians are in hospital due to COVID-19



Data Sources: MOH COVID Inpatient Census and Critical Care Information System

A 6 week stay-at-home order with a vaccination rate of at least 100K doses per day is the only way to flatten the curve.

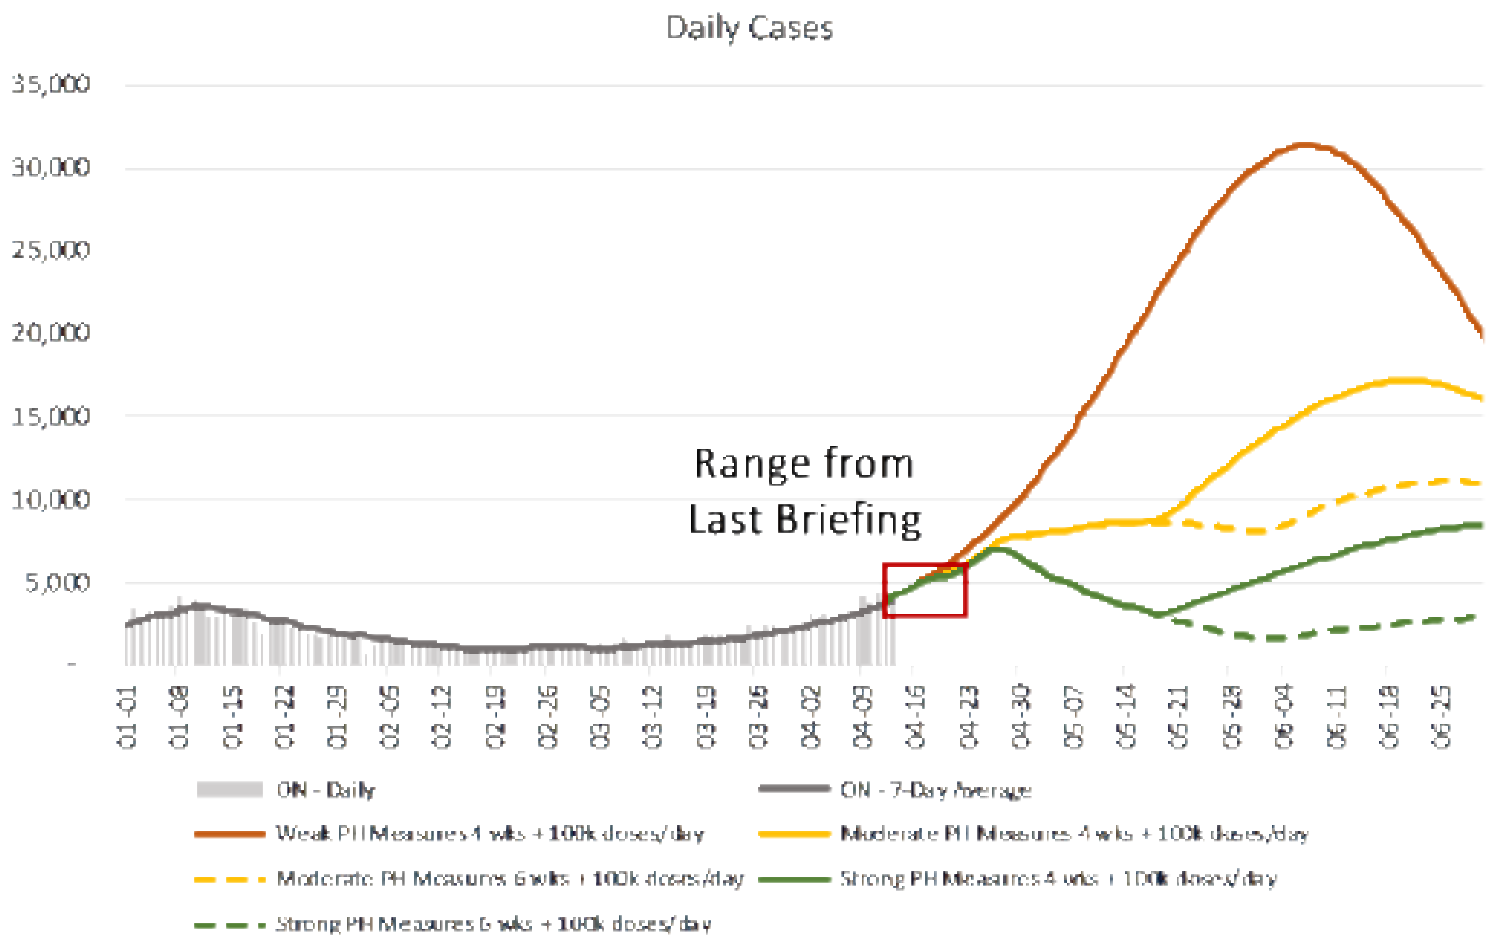
Figure summarizes predictions across 4 models with many scenarios.

Stay-at-home order assumptions:

- 4 or 6 weeks starting Apr 8
- Weak to strong effect on transmission

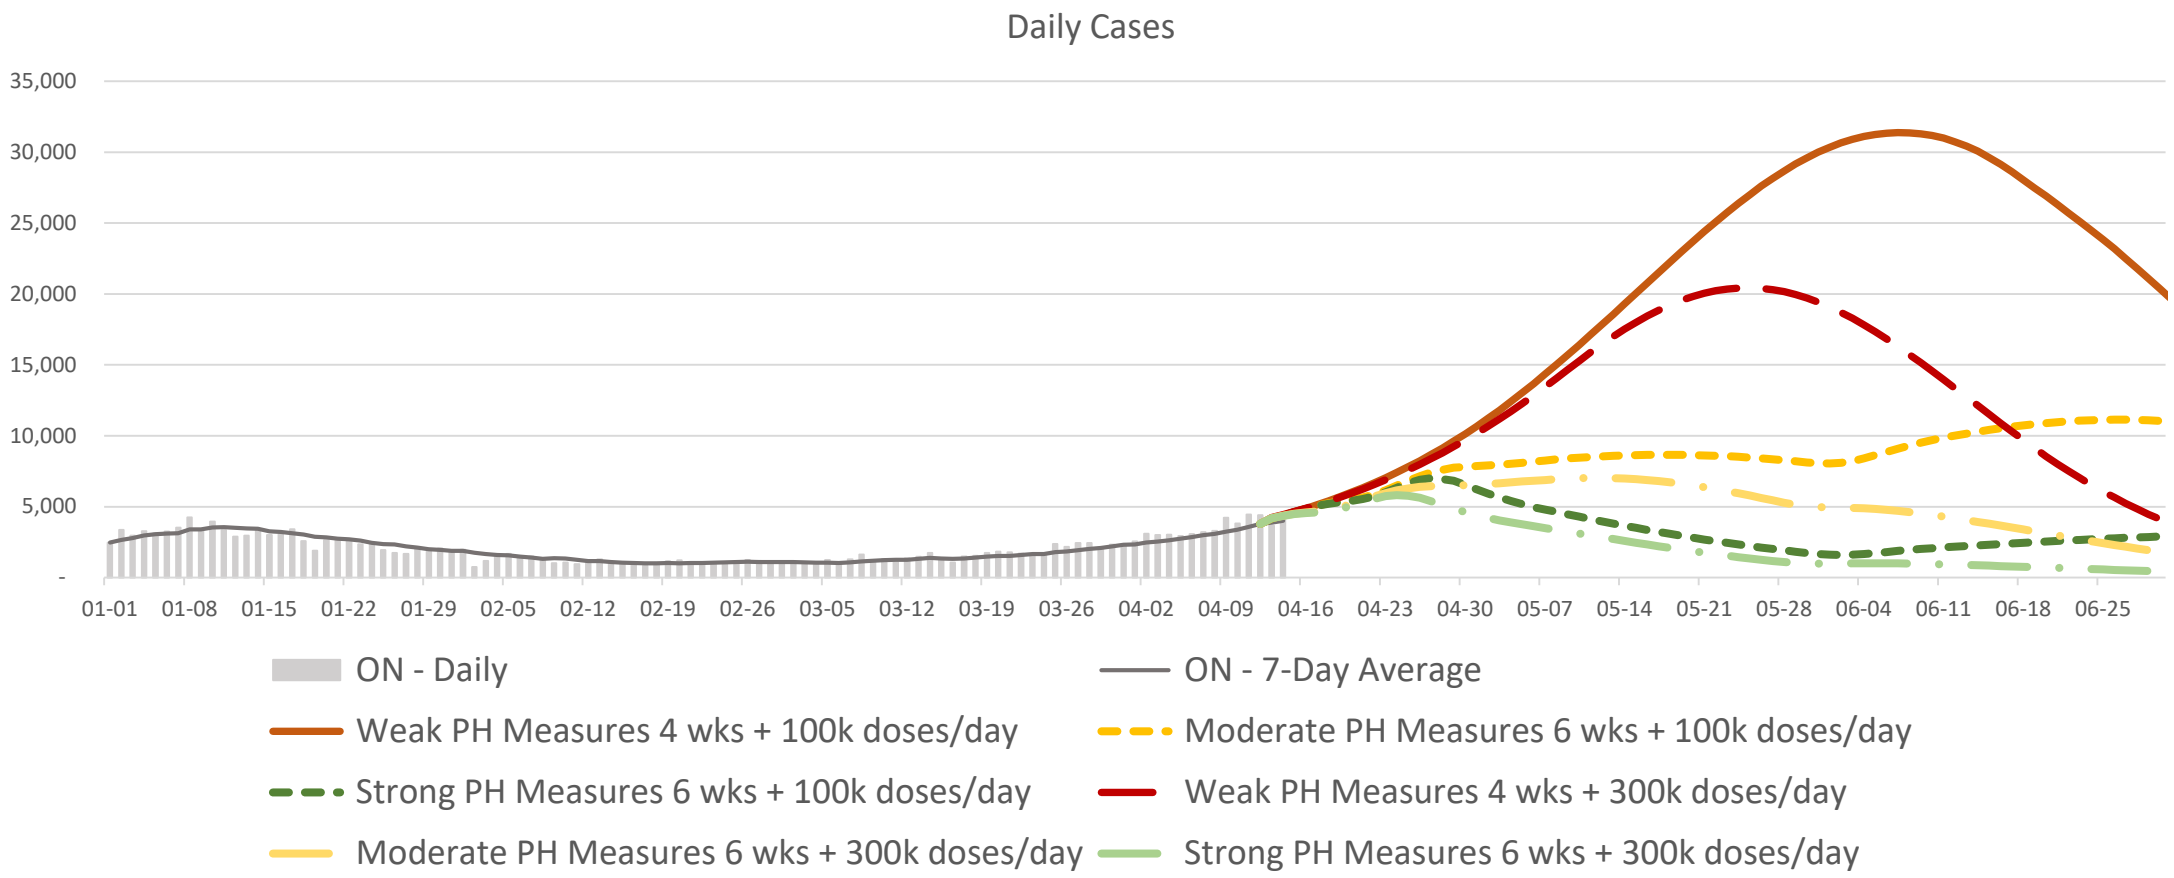
Vaccine assumptions:

- 60% effective in preventing infection
- 100,000 doses/day
- Administered at random

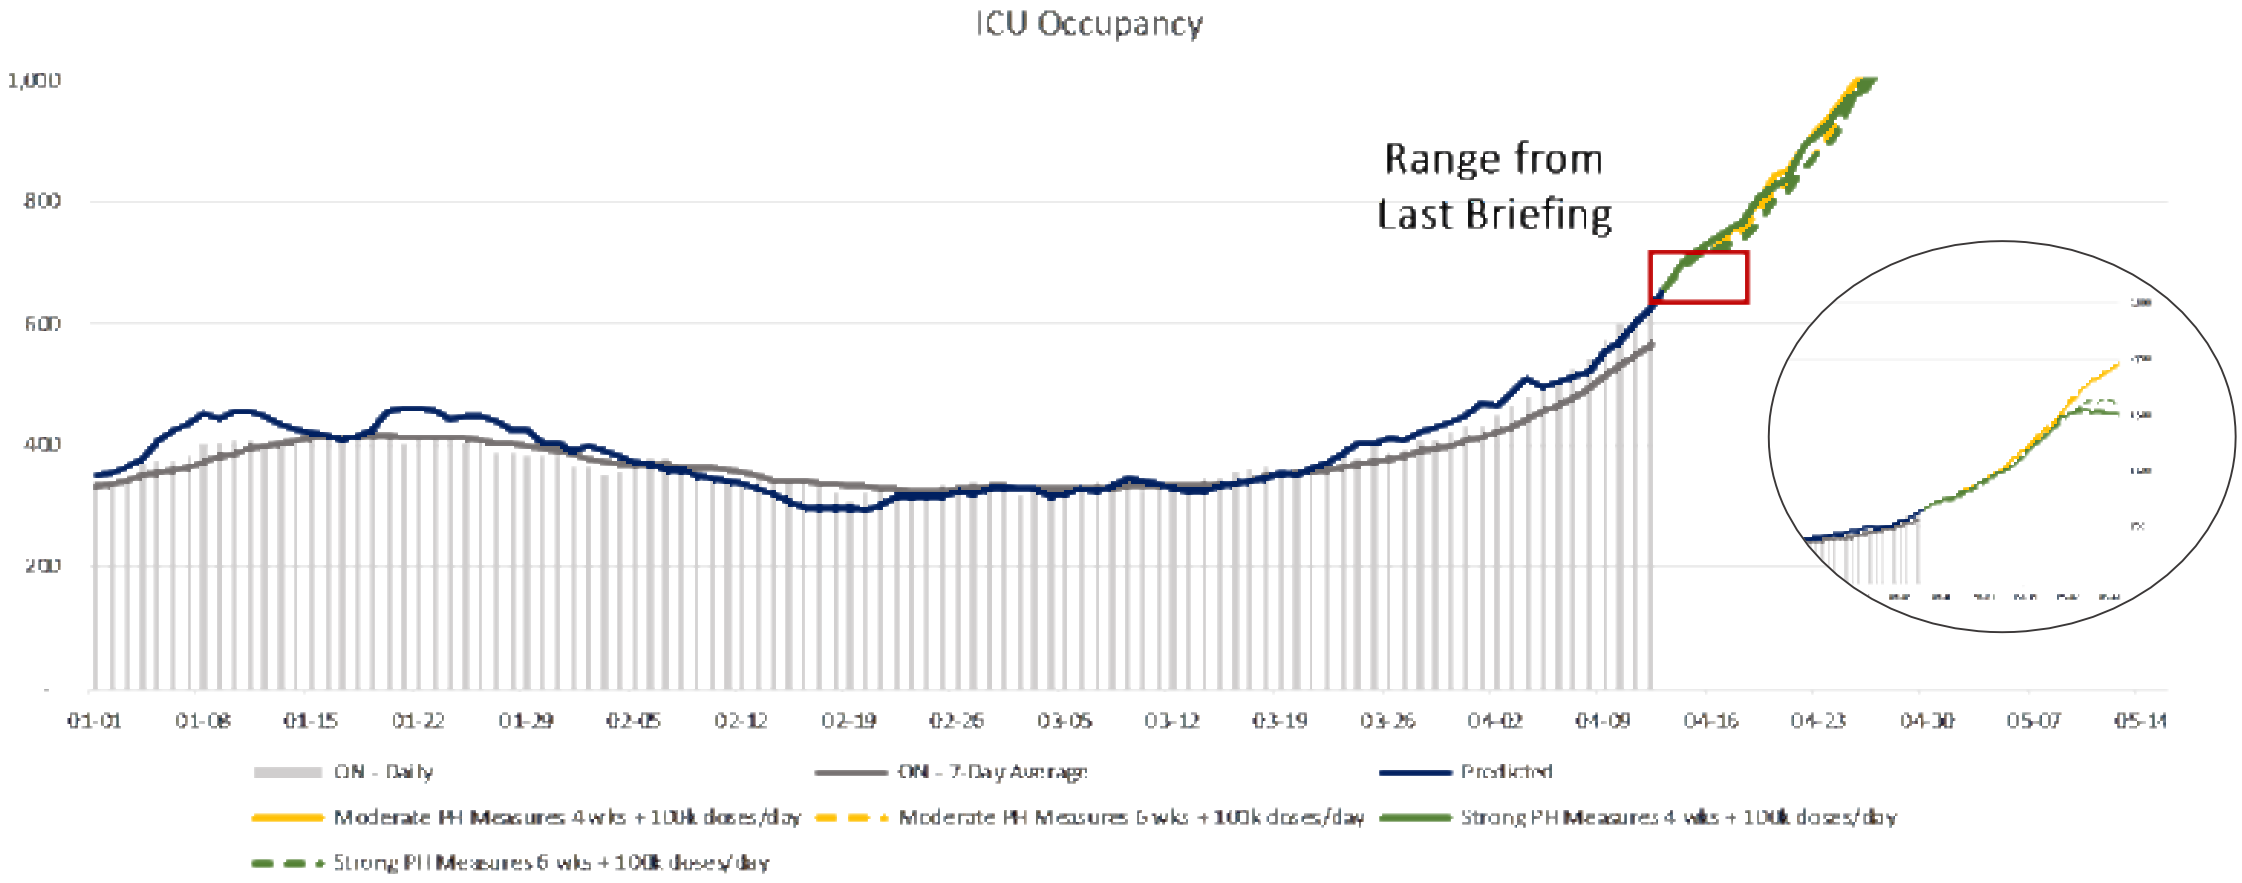


Predictions informed by modeling from COVID-19 ModCollab, Fields Institute, McMasterU, PHO, YorkU
Data (Observed Cases): covid-19.ontario.ca

Under every scenario, more vaccines mean a faster resolution in the long-run

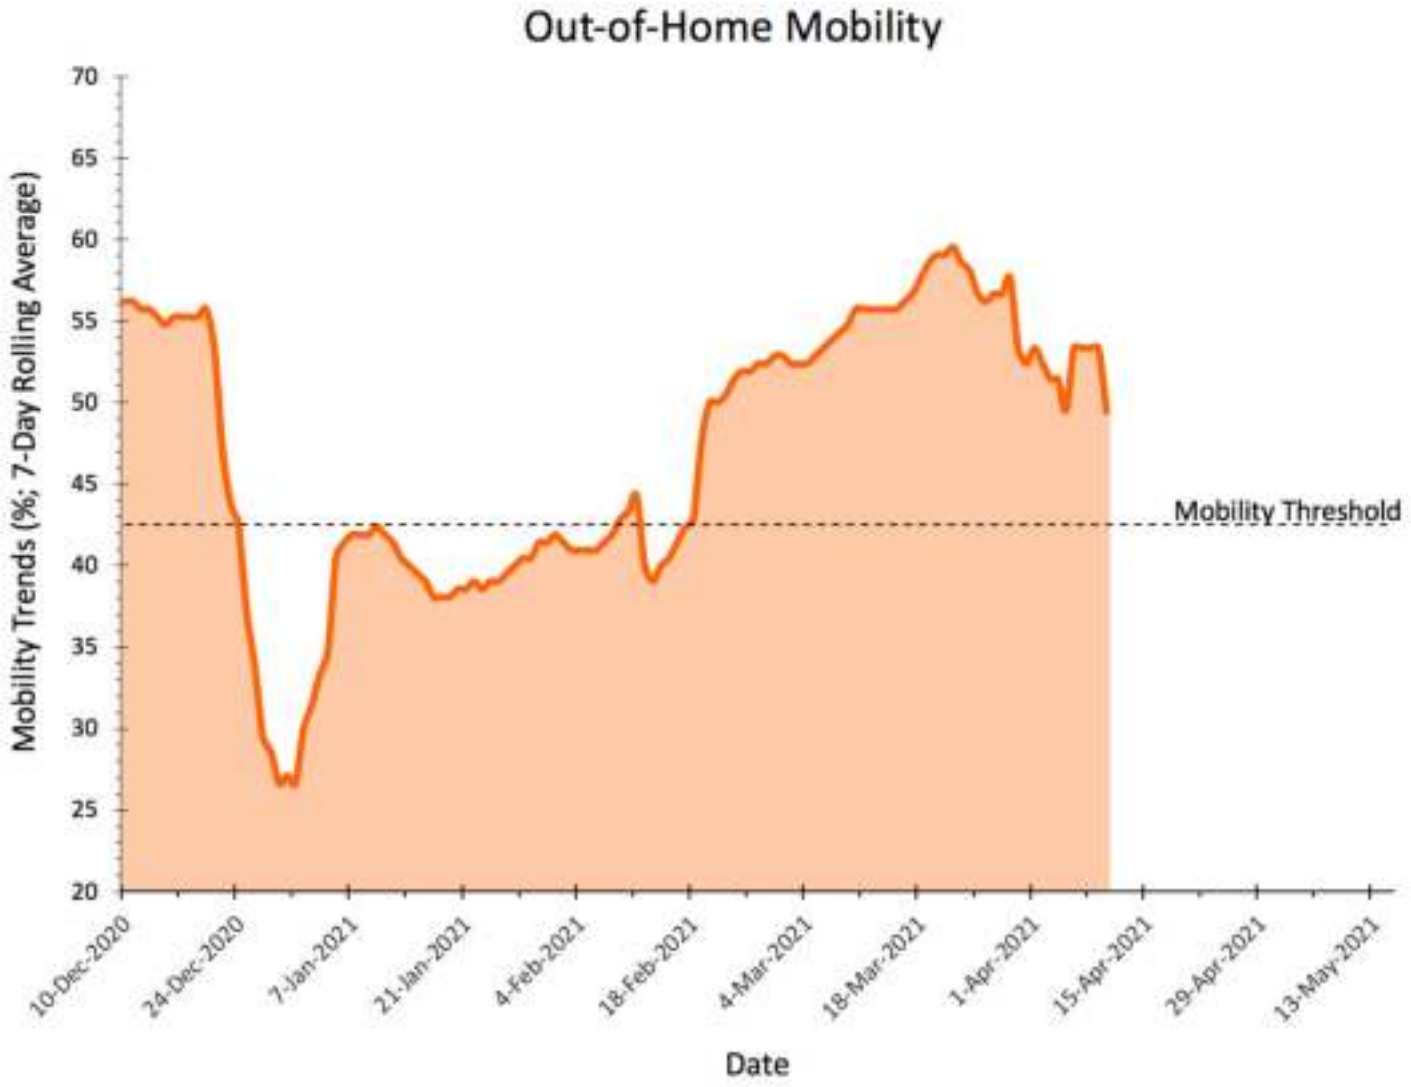


As predicted, ICU occupancy is rising dramatically. System-level public health measures will help blunt some of the impact.



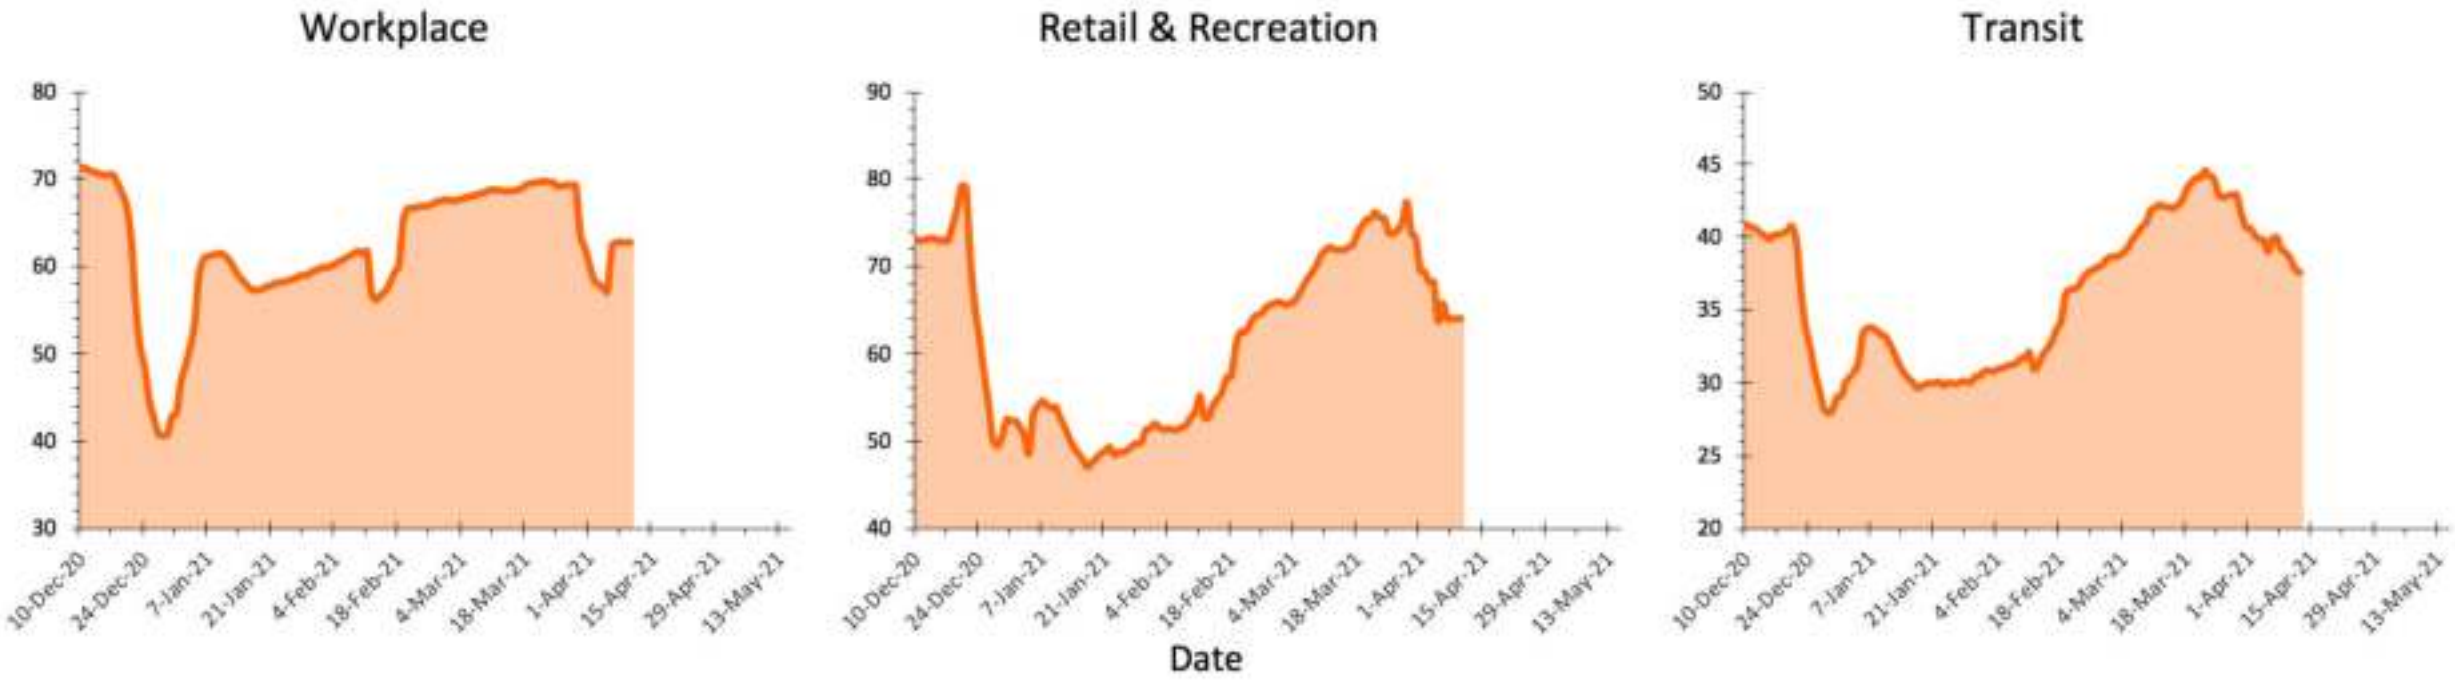
Predictions: COVID-19 ModCollab.
Data (Observed ICU Occupancy): CCSO

Mobility has declined slightly but not enough to bring current growth under control.



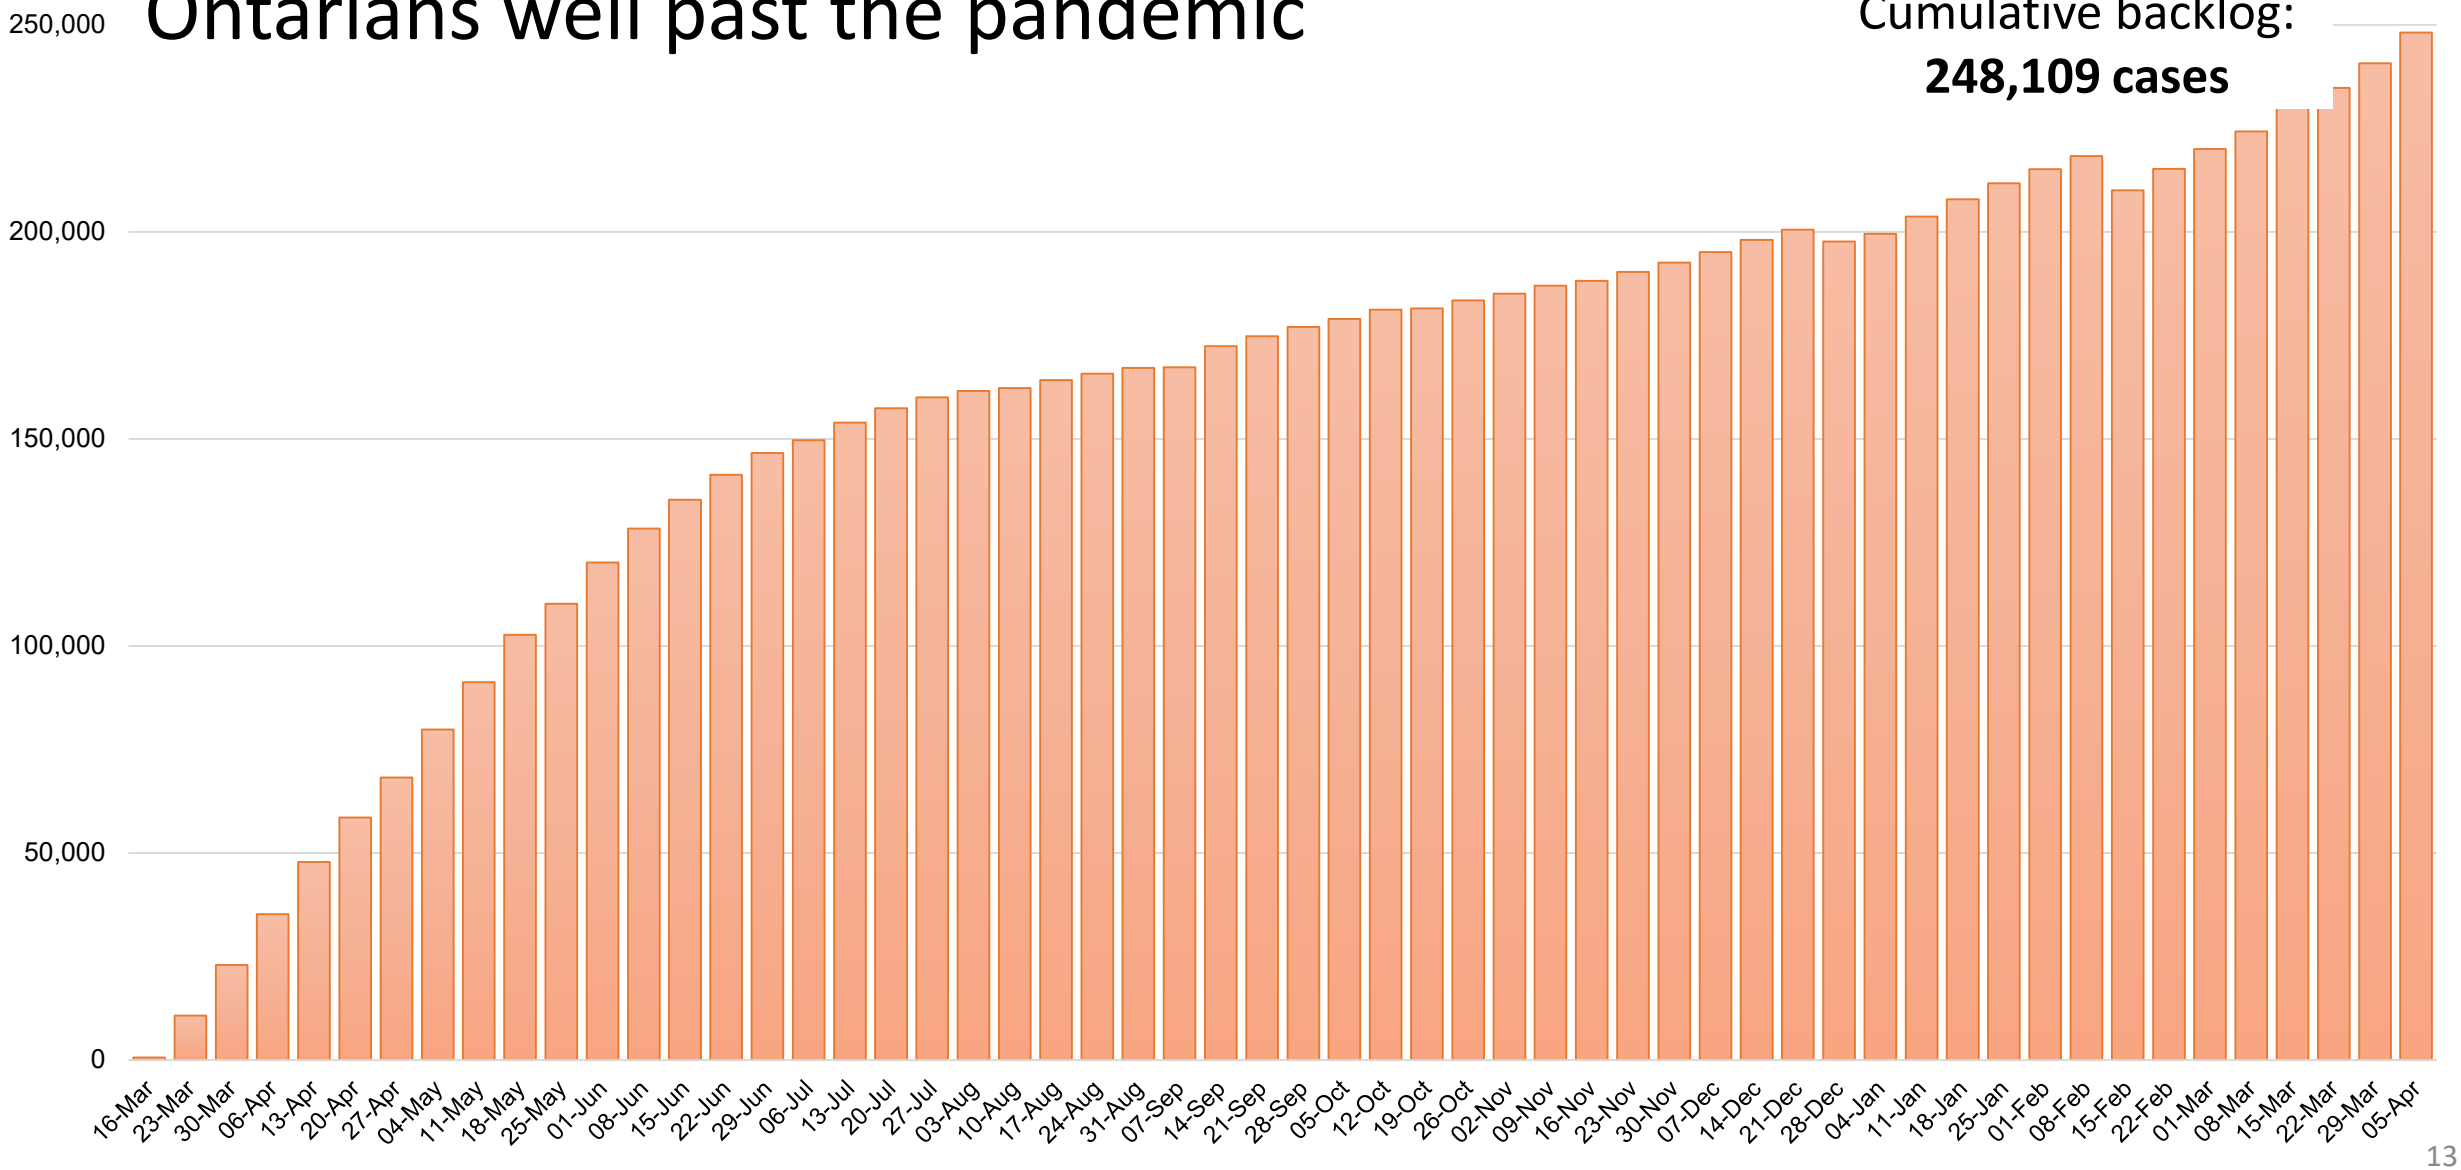
Predictions: COVID-19 SAT.
Data Google and Apple Mobility data

Mobility has declined slightly across settings. Further reducing mobility and always wearing a mask and distancing is how Ontarians help reduce cases.



Predictions: COVID-19 SAT.
Data Google and Apple Mobility data

The access to care deficit is building which will be felt by Ontarians well past the pandemic



Data Source: Wait Times Information System. Backlog estimated based on comparison of 2020/21 with 2019/20 surgical volumes

First dose vaccine coverage expanding but remains incomplete

More than 3m doses administered

NEWS RELEASE

Ontario Releases Three-Step Roadmap to Safely Reopen the Province

Province Safely Reopening Outdoor Recreational Amenities Prior to End of Stay-at-Home Order

May 20, 2021
Office of the Premier

TORONTO — The Ontario government, in consultation with the Chief Medical Officer of Health, has released its Roadmap to Reopen, a three-step plan to safely and cautiously reopen the province and gradually lift public health measures based on the provincewide vaccination rate and improvements in key public health and health care indicators. In response to recent improvements to these indicators, Ontario will allow more outdoor recreational amenities to reopen, with restrictions in place, effective May 22, 2021 at 12:01 a.m.

"As a result of the strict public health measures we introduced to stop the spread of COVID-19 variants, we are seeing a steady improvement in our situation as ICU and hospital numbers begin to stabilize," said Premier Doug Ford. "While we must remain conscious of the continued threat the virus poses, with millions of Ontarians having received at least their first dose of vaccine we can now begin the process of a slow and cautious re-opening of the province in full consultation with our public health professionals."

Roadmap to Reopen outlines three steps to easing public health measures, guided by the following principles:

- **Step One** An initial focus on resuming outdoor activities with smaller crowds where the risk of transmission is lower, and permitting retail with restrictions. This includes allowing outdoor gatherings of up to 10 people, outdoor dining with up to four people per table and non-essential retail at 15 per cent capacity.
- **Step Two** Further expanding outdoor activities and resuming limited indoor services with small numbers of people where face coverings are worn. This includes outdoor gatherings of up to 25 people, outdoor sports and leagues, overnight camps, personal care services where face coverings can be worn and with capacity limits, as well as indoor religious services, rites or ceremony gatherings at 15 per cent capacity.
- **Step Three** Expanding access to indoor settings, with restrictions, including where there are larger numbers of people and where face coverings can't always be worn. This includes indoor sports and recreational fitness; indoor dining, museums, art galleries and libraries, and casinos and bingo halls, with capacity limits.

The province will remain in each step for at least 21 days to evaluate any impacts on key public health and health system indicators. If at the end of the 21 days, the following vaccination thresholds have been met, along with positive trends in other key public health and health system indicators, then the province will move to the next step:

- **Step 1:** 60 per cent of adults vaccinated with one dose.
- **Step 2:** 70 per cent of adults vaccinated with one dose and 20 per cent vaccinated with two doses.
- **Step 3:** 70 to 80 per cent of adults vaccinated with one dose and 25 per cent vaccinated with two doses.

Based on current trends in key health indicators, including the provincial vaccination rate, the government expects to enter Step One of the Roadmap the week of June 14, 2021. The province will confirm closer to the expected start of Step One.

"While we know that now is not yet the moment to reopen, Ontarians deserve to know the path forward on what we will carefully reopen and when, starting with the settings we know are safest," said Christine Elliott, Deputy Premier and Minister of Health. "Brighter days are ahead and we believe this Roadmap represents a path out of the pandemic and will encourage Ontarians to get vaccinated and to continue following public health advice."

The provincewide emergency brake restrictions remain in effect while the province assesses when it will be moving to Step One of the roadmap with the Stay at Home order expiring on June 2, 2021. During this time, the government will continue to work with stakeholders on reopening plans to ensure full awareness of when and how they can begin to safely reopen.

Due to the continuing success of Ontario's vaccine rollout and the collective efforts of Ontarians in following public health and workplace safety measures to date, effective May 22, 2021 at 12:01 a.m. the province will reopen outdoor recreational amenities with restrictions in place, such as the need to maintain physical distancing. These amenities include but are not limited to golf courses and driving ranges, soccer and other sports fields, tennis and basketball courts, splash and spray pads and skate parks. No outdoor sports or recreational classes are permitted. Outdoor limits for social gatherings and organized public events will be expanded to five people, which will allow these amenities to be used for up to five people, including with members of different households. All other public health and workplace safety measures under the provincewide emergency brake will remain in effect.

At this time, publicly funded and private elementary and secondary schools in the province will continue to operate under teacher-led remote learning. Data will be assessed on an ongoing basis and medical experts, including the Chief Medical Officer of Health, and other health officials will be consulted to determine if it may be safe to resume in-person learning.

"Due to the stringent efforts of Ontarians following public health and workplace safety measures, we have reached the point where we can begin preparing to exit the provincewide emergency brake and lift the Stay-at-Home order," said Dr. David Williams, Chief Medical Officer of Health. "We must remain vigilant however, as the fight against COVID-19 is not over and our case counts, ICU capacity and hospitalizations are still concerning. It remains critical that all Ontarians continue to follow all public health and workplace safety measures currently in place to help further reduce transmission and save lives."

The government will continue to work with the Public Health Measures Table, Public Health Ontario, and other public health and scientific experts to determine public health guidance for Ontarians to follow, including protocols for masking and outdoor/indoor gatherings, after being fully vaccinated.

Quick Facts

- Based on the latest modelling data COVID-19 case, positivity and hospitalization rates are decreasing, and control of the pandemic is improving. Maintaining the current rate of vaccination and public health and workplace safety measures will help to ensure Ontario starts to safely and gradually reopen.
- Ontario has administered first doses of the COVID-19 vaccines to over 58.5 per cent of Ontarians aged 18 and over. Over two million doses of the COVID-19 vaccine have been administered in Ontario since the start of May, and the province remains on track to have administered first doses to 65 per cent of Ontarians aged 18 and over by the end of May.
- The government has extended the provincewide Stay-at-Home Order until June 2, 2021, and has maintained all public health and workplace safety measures under the provincewide emergency brake to help to stop the rapid transmission of COVID-19 variants in communities, protect hospital capacity and save lives.
- The Stay-at-Home order currently in effect requires everyone to remain at home except for specified purposes, such as going to the grocery store or pharmacy, accessing health care services (including getting vaccinated), for outdoor exercise, or for work that cannot be done remotely.
- If passed by the Legislature, powers under the Reopening Ontario (A Flexible Response to COVID-19) Act, 2020 (ROA) will be extended to December 1, 2021 to ensure public health measures currently in place can be extended and adjusted as necessary, to deal with the impacts of COVID-19 and support a gradual re-opening of the province. There are currently 29 orders in effect under the ROA. Orders can be extended for up to 30 days at a time under the ROA, and the government must report on all order extensions to the Select Committee on Emergency Management Oversight.
- As of 8:00 a.m. on Tuesday, May 18, 2021, individuals aged 18 and over in 2021 across Ontario are eligible to book a COVID-19 vaccine appointment through the provincial booking system and call centre, or directly through public health units that use their own booking system.

EVIDENCE BRIEF

Considerations for Public Health Measures for Individuals with Partial Vaccination for SARS-CoV-2

Date: 04/15/2021

Key Messages

- Effectiveness of the first dose of a two-dose vaccination schedule of vaccines available in Canada to prevent symptomatic or asymptomatic severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection ranges between 60-80% at approximately 21-28 days after first dose; however, data indicate that the current viral vector vaccine in Canada (i.e., AstraZeneca) has less first-dose effectiveness than mRNA vaccines (i.e., Pfizer-BioNTech and Moderna).

- Clear messaging is required for the public to understand that the protective effects of the first dose of the vaccines takes weeks to develop and is neither immediate nor the same as being fully vaccinated. Further, an individual's risk factors for severe SARS-CoV-2 infection (e.g., age, immunocompromise) can impact vaccine effectiveness. Nonetheless, widespread coverage with a first dose would be sufficient to lower case rates in the population thereby allowing reductions in population level measures rather than individual level measures.

- No jurisdictions with total population vaccination programs using vaccines approved in Canada have indicated that societal public health measures can be relaxed for partially vaccinated individuals.

- Relaxing public health measures for partially vaccinated individuals is not advisable; current public health measures should remain for partially vaccinated individuals. Focus should be turned to rapidly deploying vaccine to have high first-dose coverage in the population, including reducing health inequities related to accessing first dose vaccination in the communities with the highest rates of SARS-CoV-2 that are also more likely to be of low socioeconomic status.

Issue and Research Question

This evidence brief explores whether or not it would be advisable to loosen public health measures recommended for individuals after a single dose of a two-dose vaccination schedule (also termed partially vaccinated individuals or series initiation) for SARS-CoV-2. This evidence brief does not address recommendations that are specific to health care workers who are partially vaccinated, or case/contact measures for individuals who are partially vaccinated.

Currently in Ontario, there is a low proportion of partially and fully vaccinated individuals.[1] Incentives to receive the first dose of a vaccine given the long period between vaccine doses will be called upon by the public. However, any incentives must be based on available evidence and expert opinion such that the pandemic is controlled and moves towards a return to a new normal with respect to public health measures. Moreover, at this time there are no recommendations for public health measures affecting fully vaccinated individuals in the general community in Ontario at this time.

Methods

The National Advisory Committee on Immunization (NACI) has released a summary and review of vaccine intervals in Canada in the context of limited vaccine supply.[2] The review is recent to late March 2021. The NACI report has been reviewed and briefly summarized alongside evidence from previous reports from Public Health Ontario (PHO), with a focus on the points relevant to considerations for public health measures for individuals who have been partially vaccinated (received the first of a two-dose vaccination schedule) against SARS-CoV-2.[3]

Main Findings

Vaccine Effectiveness after a First Dose of Vaccine

Vaccine efficacy to prevent symptomatic disease from clinical trial data with Pfizer-BioNTech and Moderna 14 days after the first dose and up until the second dose (typically either 21 or 28 days post-first dose) is estimated to be 92%.[2] For AstraZeneca, the efficacy to prevent symptomatic disease from clinical trial data between 22 and 90 days after the first dose was reported to be 76%.[2]

Real-world vaccine effectiveness (VE) data are predominantly from non-peer reviewed preprint publications using different study designs, dose intervals, study populations, outcomes measured (e.g., laboratory confirmed versus hospitalizations or deaths), and outcome dates (e.g., date of symptom onset, specimen collection). Results reported for each vaccine, mostly pertaining to mRNA vaccines, varied considerably.

The following summary of real-world VE is for vaccines intended to be given as a 2-dose regimen that have been approved by Health Canada as of April 8, 2021 (Pfizer-BioNTech COVID-19 vaccine [BNT162b2], Moderna COVID-19 vaccine [mRNA-1273], Oxford University/AstraZeneca [AZD1222/ChAdOx1-S]) and is based on the PHO's *COVID-19 Real-World Vaccine Effectiveness – What We Know So Far* document and the NACI Statement on Extended dose intervals for COVID-19 vaccines.[2,4] There is currently limited VE data on specific populations who are at increased risk of severe outcomes from COVID-19 and who may have a suboptimal immune response. While emerging data has helped to identify special populations (e.g., transplant patients, individuals with malignant hematological disorders or solid tumors on active therapy) as potentially having a lower response to a first dose of vaccine, a comprehensive list of other groups that may experience decreased response from a single dose has not yet been identified due to lack of data.[5] Therefore, it is important to note that the following summary of VE after a first dose of vaccine pertains to the general, community-dwelling population.

Recognizing differences between specific vaccines and populations studied, overall VE is good 21-28 days after the first dose of vaccine. Real-world studies have reported VE of 60 to 80% for preventing SARS-CoV-2 infection (asymptomatic and symptomatic COVID-19 disease) 3-4 weeks after receiving a single dose of Pfizer, Moderna or AstraZeneca vaccine; this increases to greater than 85% after a second

dose.[6-9] The VE for preventing severe disease and COVID-19-related hospitalization is 70 to 90% after the first dose of vaccine and the VE for reducing deaths attributable to COVID-19 is 70 to 85% after the first dose.[9-11] After a second dose, VE for prevention of severe disease and hospitalization increases with most estimates of VE being greater than 90%.[6,12] Please see COVID-19 Real-World Vaccine Effectiveness – What We Know So Far for further detail including study characteristics.[4]

The VE for preventing asymptomatic infection is particularly important given the challenges of preventing asymptomatic transmission with other public health measures. Data from Israel indicate that VE for preventing asymptomatic infection is 29%, 14 to 20 days after the first dose, and 52%, 21 to 27 days, after the first dose, increasing to 90%, 7 days after the second dose which is likely a first dose effect given timing. However it is important to note that this was in the context of a rapid decline in cases amidst deployment of a national vaccine campaign and in the absence of systematic asymptomatic testing.[6] A US retrospective cohort study of asymptomatic patients undergoing screening before surgical and medical procedures found a VE of 79% more than 10 days after the first dose (before the second dose) and a VE of 80% after the second dose. However the VE after the second dose was estimated starting at 0 days after the second dose, which also likely represents a first dose effect.[13]

Emerging data demonstrates that vaccination is associated with reduced spread in individuals and populations, regions, or facilities with higher rates of vaccination or those that were vaccinated earlier than others. However, these estimates are for individuals receiving *at least one dose* of vaccine and includes individuals that have received 2 doses.

- In an observational study in Israel, breakthrough infections occurring 12-37 days after individuals received the first dose of the Pfizer vaccine had significantly reduced viral loads at the time of testing, potentially decreasing viral shedding and contagiousness of the disease.[14]

- An analysis of early statewide vaccination efforts in the US found that vaccination was effective in reducing daily COVID-19 case growth rates by 0.124, 0.347, 0.345, 0.464, 0.490, and 0.756 percentage point declines, respectively, in the 1-5, 6-10, 11-15, 16-20, 21-25, and 26 or more days after the start of vaccination (i.e., administration date of first COVID-19 vaccine dose).[15]

- A separate analysis of vaccination rates and COVID-19 incidence found that the cumulative county-level vaccination rate in the US (percentage of the county population who have received at least one dose) was significantly associated with a corresponding decline in COVID-19 incidence; that is, higher vaccination rates translated to a decreased county-level COVID-19 incidence.[16]

- In Israel, where COVID-19 cases and hospitalizations started to decline after implementation of a national vaccine campaign that prioritized vaccination of older individuals, an analysis between early-vaccinated cities and late-vaccinated cities found a larger and earlier decrease in the number of COVID-19 cases and hospitalizations of older individuals (> 60 years) in earlier compared to later-vaccinated cities. While a concurrent lockdown could have also influenced results, the study authors noted that these same downward trends in older individuals were not observed during previous lockdowns in which measures of clinical outcomes had similar dynamics across age groups. At the time of the study, 68.7% of individuals over 16 years had received the first dose and 48% had received the second dose of vaccine.[17]

Extended Dose Intervals for COVID-19 Vaccines in Canada

The NACI recommendation to allow for an extended interval between first and second doses of vaccine aims to minimize death and disease at a population level by immunizing as many individuals, as quickly as possible in the context of a limited supply.[18] This recommendation was informed by modelling developed by the Public Health Agency of Canada (PHAC) which compared the impact of different vaccination strategies under real-world effectiveness conditions.[19] Results showed that longer intervals of up to 6 months between the first and second dose prevented more hospitalizations and deaths. Conditions under which extended dose intervals led to worse outcomes included VE of less than 65% for preventing death after the first dose or protection waning to 0% by month 3 before the scheduled second dose at 6 months. Achieving the benefits of the extended dose interval strategy greatly depends on accelerated, widespread first dose vaccine coverage in individuals 20-74 years old since older adults were prioritized for early vaccination.[19]

Jurisdictional Responses to Public Health Measures Based on the Two-dose Vaccination Schedule for SARS-CoV-2

In brief, Canada, England, Scotland, Denmark, United States, and Israel all do not have public health measures specific to individuals who are partially vaccinated (i.e., single dose in a two-dose vaccine schedule) even though some of these countries have high vaccine coverage.[3,20-29]

Discussion and Conclusions

Vaccination, including after the first dose of a two-dose vaccine schedule, provides significant protection from symptomatic disease and severe outcomes such as hospitalization and death compared to not being vaccinated against SARS-CoV-2. Therefore, it is expected that widespread coverage of the population with the first dose of vaccine will lower case rates in the population. However, there is no evidence whether a single dose of a two-dose vaccine schedule will either increase or decrease the emergence of VOC.[2]

Those countries that are leading in total population vaccination coverage have not opted to reduce observed public health measure recommendations to partially vaccinated individuals. The rationale for not having different public health measures for partially vaccinated individuals has not been described by the jurisdictions reviewed, although we note that some jurisdictions (i.e., Israel) chose to provide both doses of a two-dose regimen within a shorter interval than Ontario. A literature review on the topic was not performed for this evidence brief.

Implications for Practice

Public health messaging regarding vaccination needs to be transparent about decision-making reasons in order to avoid unintended negative impacts such as public mistrust impacting vaccination uptake or willingness to follow public health measures. Ontario's vaccine coverage, including proportion of the population having received a first dose, lags behind countries that have been able to follow recommended vaccination schedules and sufficient procurement. At this time, with low proportions of partially vaccinated and fully vaccinated individuals in the Ontario population,[1] and in the context of high disease incidence including VOC, it is not advisable to reduce public health measures for partially vaccinated individuals despite data demonstrating decreased incidence in asymptomatic and symptomatic disease, and data is still needed regarding risk of transmission to others after receiving the

first dose of a vaccine available in Canada. Moreover, VOC for which reduced vaccine efficacy for in vitro studies and effectiveness is documented, will continue to pose a higher risk to the community until there is low circulation of SARS-CoV-2 overall.

Valuable data for vaccines available in Canada that are still needed to better inform decisions regarding public health measures for partially vaccinated individuals includes: real world data of implications from countries with more comprehensive vaccination coverage enacting public health measures for partially vaccinated individuals, effectiveness of partially vaccinated versus fully vaccinated individuals including a time to event analysis (e.g., hazard analysis), what individual level factors influence first-dose vaccine effectiveness, risk of spread from partially vaccinated individuals to unvaccinated individuals, duration of immunity from single dose vaccination, effectiveness of single dose vaccination in subgroups that have not been studied, and what influence that changes to public health measures for partially vaccinated and/or fully vaccinated individuals may have on vaccine uptake for one dose and both doses.

Current data from Forward Sortation Area (first three digits of the postal code) analyses in Toronto show that the areas with the highest burden of disease have the lowest vaccine coverage rates.[30] News reports have stated that the analyses indicates higher socioeconomic status neighbourhoods in Toronto, based on postal code and census data, have higher vaccine coverage than low socioeconomic neighbourhoods where rates of SARS-CoV-2 and severe outcomes of COVID-19 are higher.[31,32] Hot spot communities are known to often have higher concentrations of populations who are disproportionately affected by COVID-19 in Ontario due to a number of intersecting equity factors and factors related to the determinants of health. These populations include Black, racialized, lower income and materially deprived communities.[33] Focusing strategies to vaccinate these populations at risk is already proposed in Phase 2 of Ontario's vaccination plan.[33,34]

NEWS RELEASE

Ontario Maintains COVID-19 Restrictions as Stay-at-Home Order is Set to Expire

Measures address ongoing risks as province prepares to safely and cautiously reopen

June 01, 2021
Solicitor General

TORONTO — As was previously announced, Ontario's Stay-at-Home order will expire on June 2, 2021. When it does, all other public health and workplace measures will remain in place provincewide until Ontario enters Step One of the Roadmap to Reopen, at which point some restrictions will ease with an initial focus on outdoor settings.

"We've seen great progress in our fight against COVID-19 in recent weeks, but now is not the time to let our guard down," said Solicitor General Sylvia Jones. "With the Stay-At-Home order set to expire, we need to provide people with certainty so that they can continue to follow public health guidance. Doing so will help us to meet our goal of starting to gradually lift some restrictions when we enter Step One of the Roadmap when it is safe to do so."

On April 7, 2021, in response to the rapid increase in COVID-19 transmission driven by new, more contagious variants, the Ontario government declared a provincial emergency and issued a Stay-at-Home order as well as enhanced public health measures. In a concentrated effort to reduce mobility and opportunities for transmission, the Stay-At-Home order required Ontarians to remain at home except for the purposes set out in the order, such as exercise, going to the grocery store or pharmacy, or accessing health care services. Once the Stay-at-Home order expires on June 2, these restrictions will no longer be in effect.

However, all other existing measures will remain in place provincewide, including restrictions on gatherings, businesses, services and activities. This includes limiting indoor gatherings to households only and outdoor gatherings to up to five people, subject to limited exceptions, maintaining a cap of 25 per cent capacity for essential retail where only certain goods are permitted to be sold, restricting non-essential retail to curbside pickup and delivery only, as well as limiting short-term rentals to individuals in need of housing and allowing Ontario Parks and campgrounds on public lands to be used for day-use only, subject to limited exceptions.

Ontarians will be able to leave home to travel within the province to a secondary residence for any reason, however, they are not be permitted to host members of another household indoors except for a person from another household who lives alone or a caregiver.

A simple, easy-to-understand summary of restrictions can be found on the province's "Reopening Ontario" webpage, which provides details on what public health measures are in place before the province enters Step One of the Roadmap to Reopen. As always, anyone who may have been exposed to COVID-19 or who may be exhibiting symptoms of the virus should use the province's self-assessment tool to determine what they should do next, including getting a test and isolating if necessary.

"As we continue to accelerate second doses of the COVID-19 vaccine for Ontarians, maintaining public health measures will ensure we continue to protect our hospital capacity and help stop the spread of COVID-19 variants," said Christine Elliott, Deputy Premier and Minister of Health. "As we look towards Step One of Ontario's Roadmap and begin to gradually lift public health measures, it remains critical that all Ontarians continue to follow public health advice and roll up their sleeves to receive the vaccine. Every dose administered means we are one step closer to the end of the pandemic."

With the expiry of the Stay-at-Home order, emergency order O. Reg 266/21 (Residential Evictions) will also expire on June 2, 2021. Emergency orders currently in effect under the *Emergency Management and Civil Protection Act* have been extended until June 16, 2021:

- O. Reg. 8/21 Enforcement of COVID-19 Measures
- O. Reg. 55/21 Compliance Orders for Retirement Homes
- O. Reg. 271/21 Work Redeployment for Local Health Integration Networks and Ontario Health
- O. Reg. 272/21 Transfer of Hospital Patients

- O. Reg. 288/21 Closure of Public Lands for Recreational Camping
- O. Reg. 293/21 Persons Entering Ontario From Manitoba or Quebec
- O. Reg. 304/21 Work Redeployment for Independent Health Facilities
- O. Reg. 305/21 Regulated Health Professionals
- O. Reg. 317/21 Agreements Between Health Service Providers and Retirement Homes

Update on COVID-19 Projections

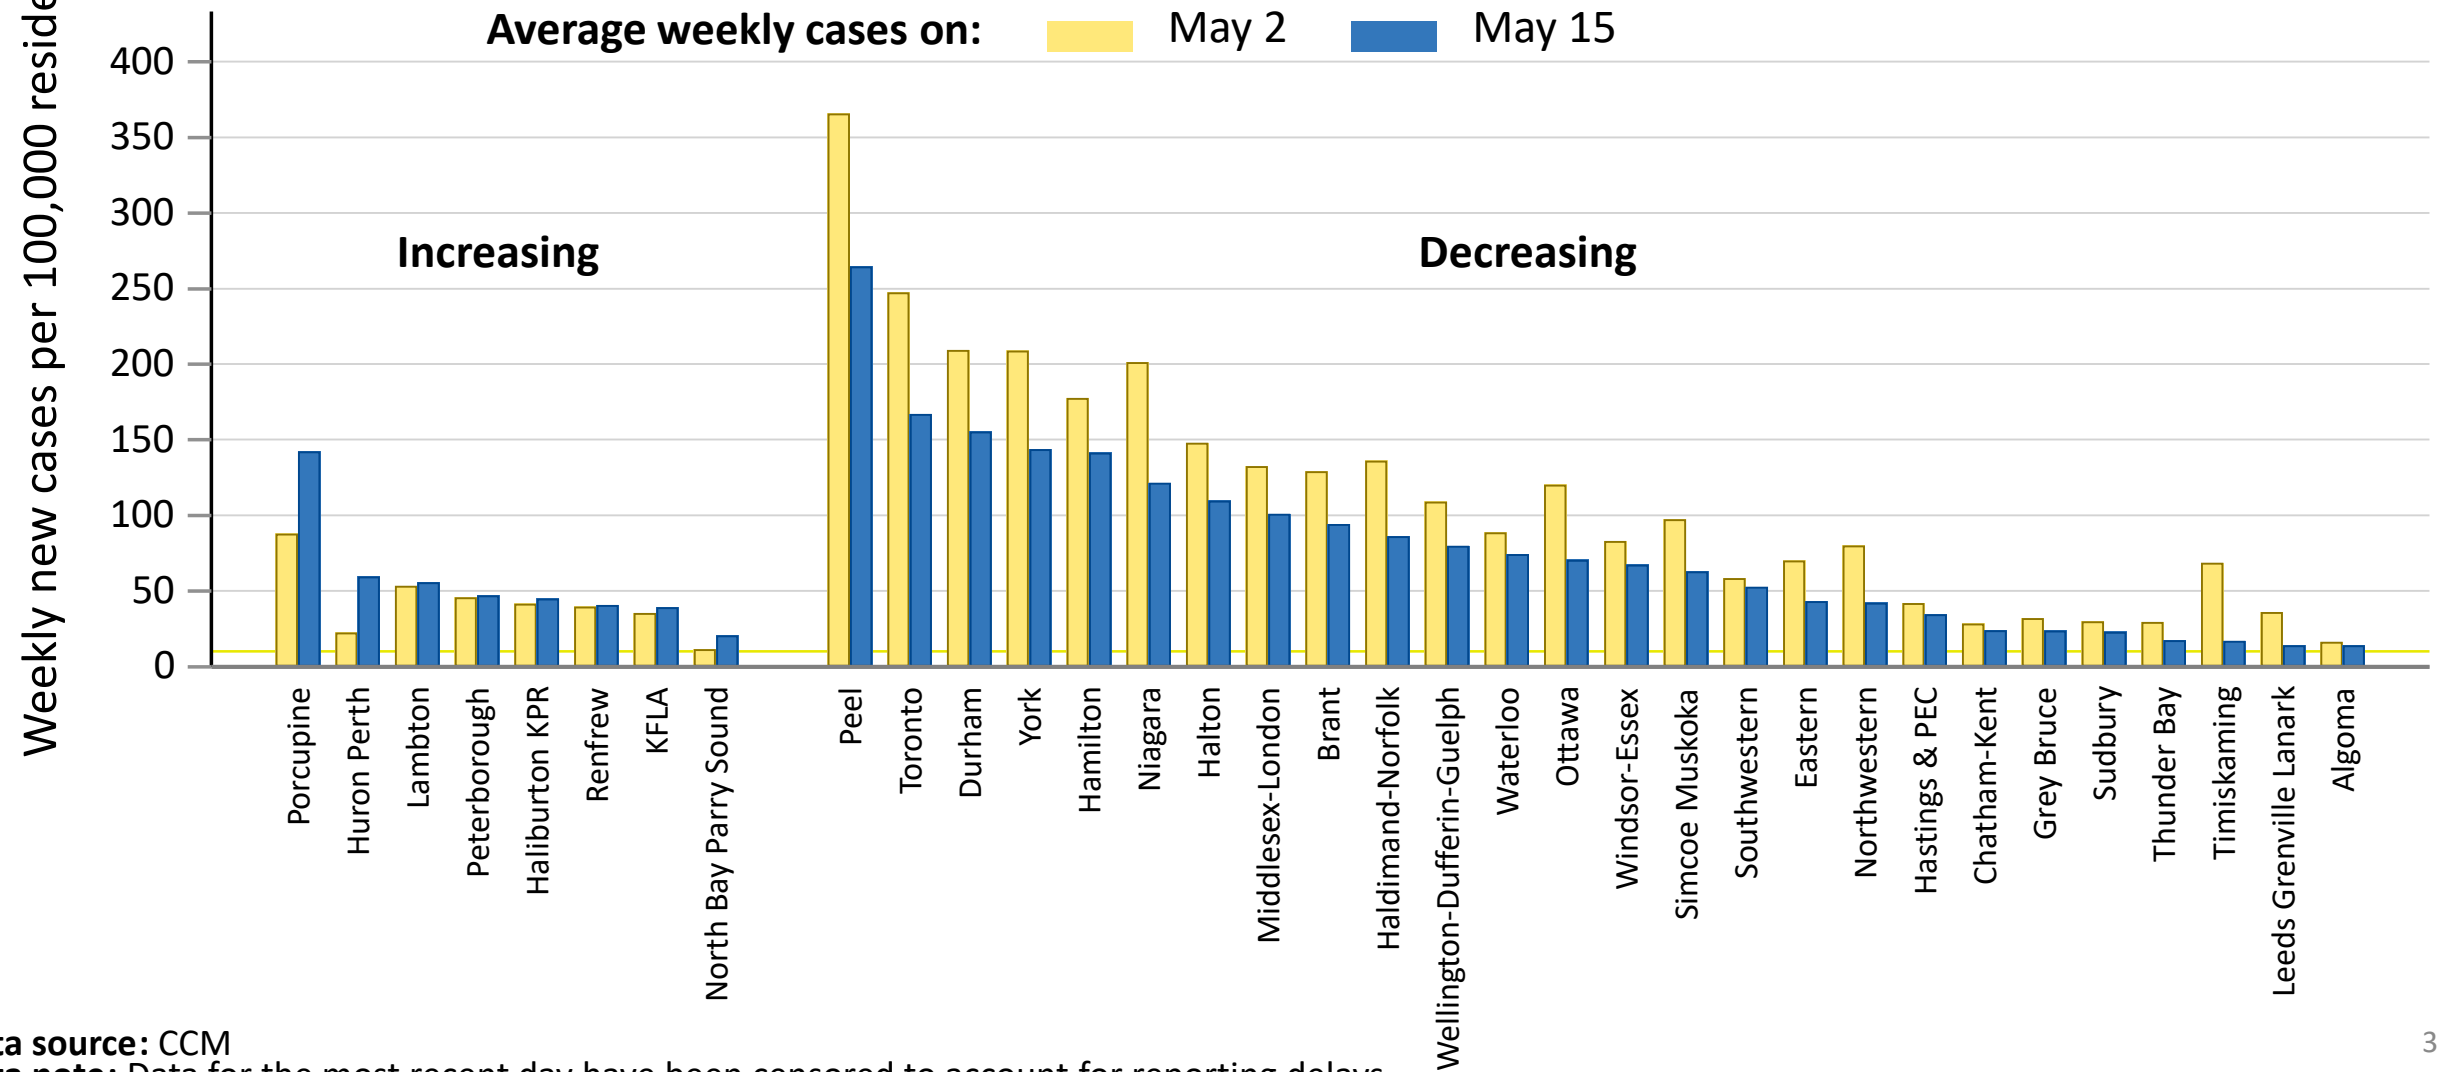
Science Advisory and Modelling Consensus Tables

May 20, 2021

Key Findings

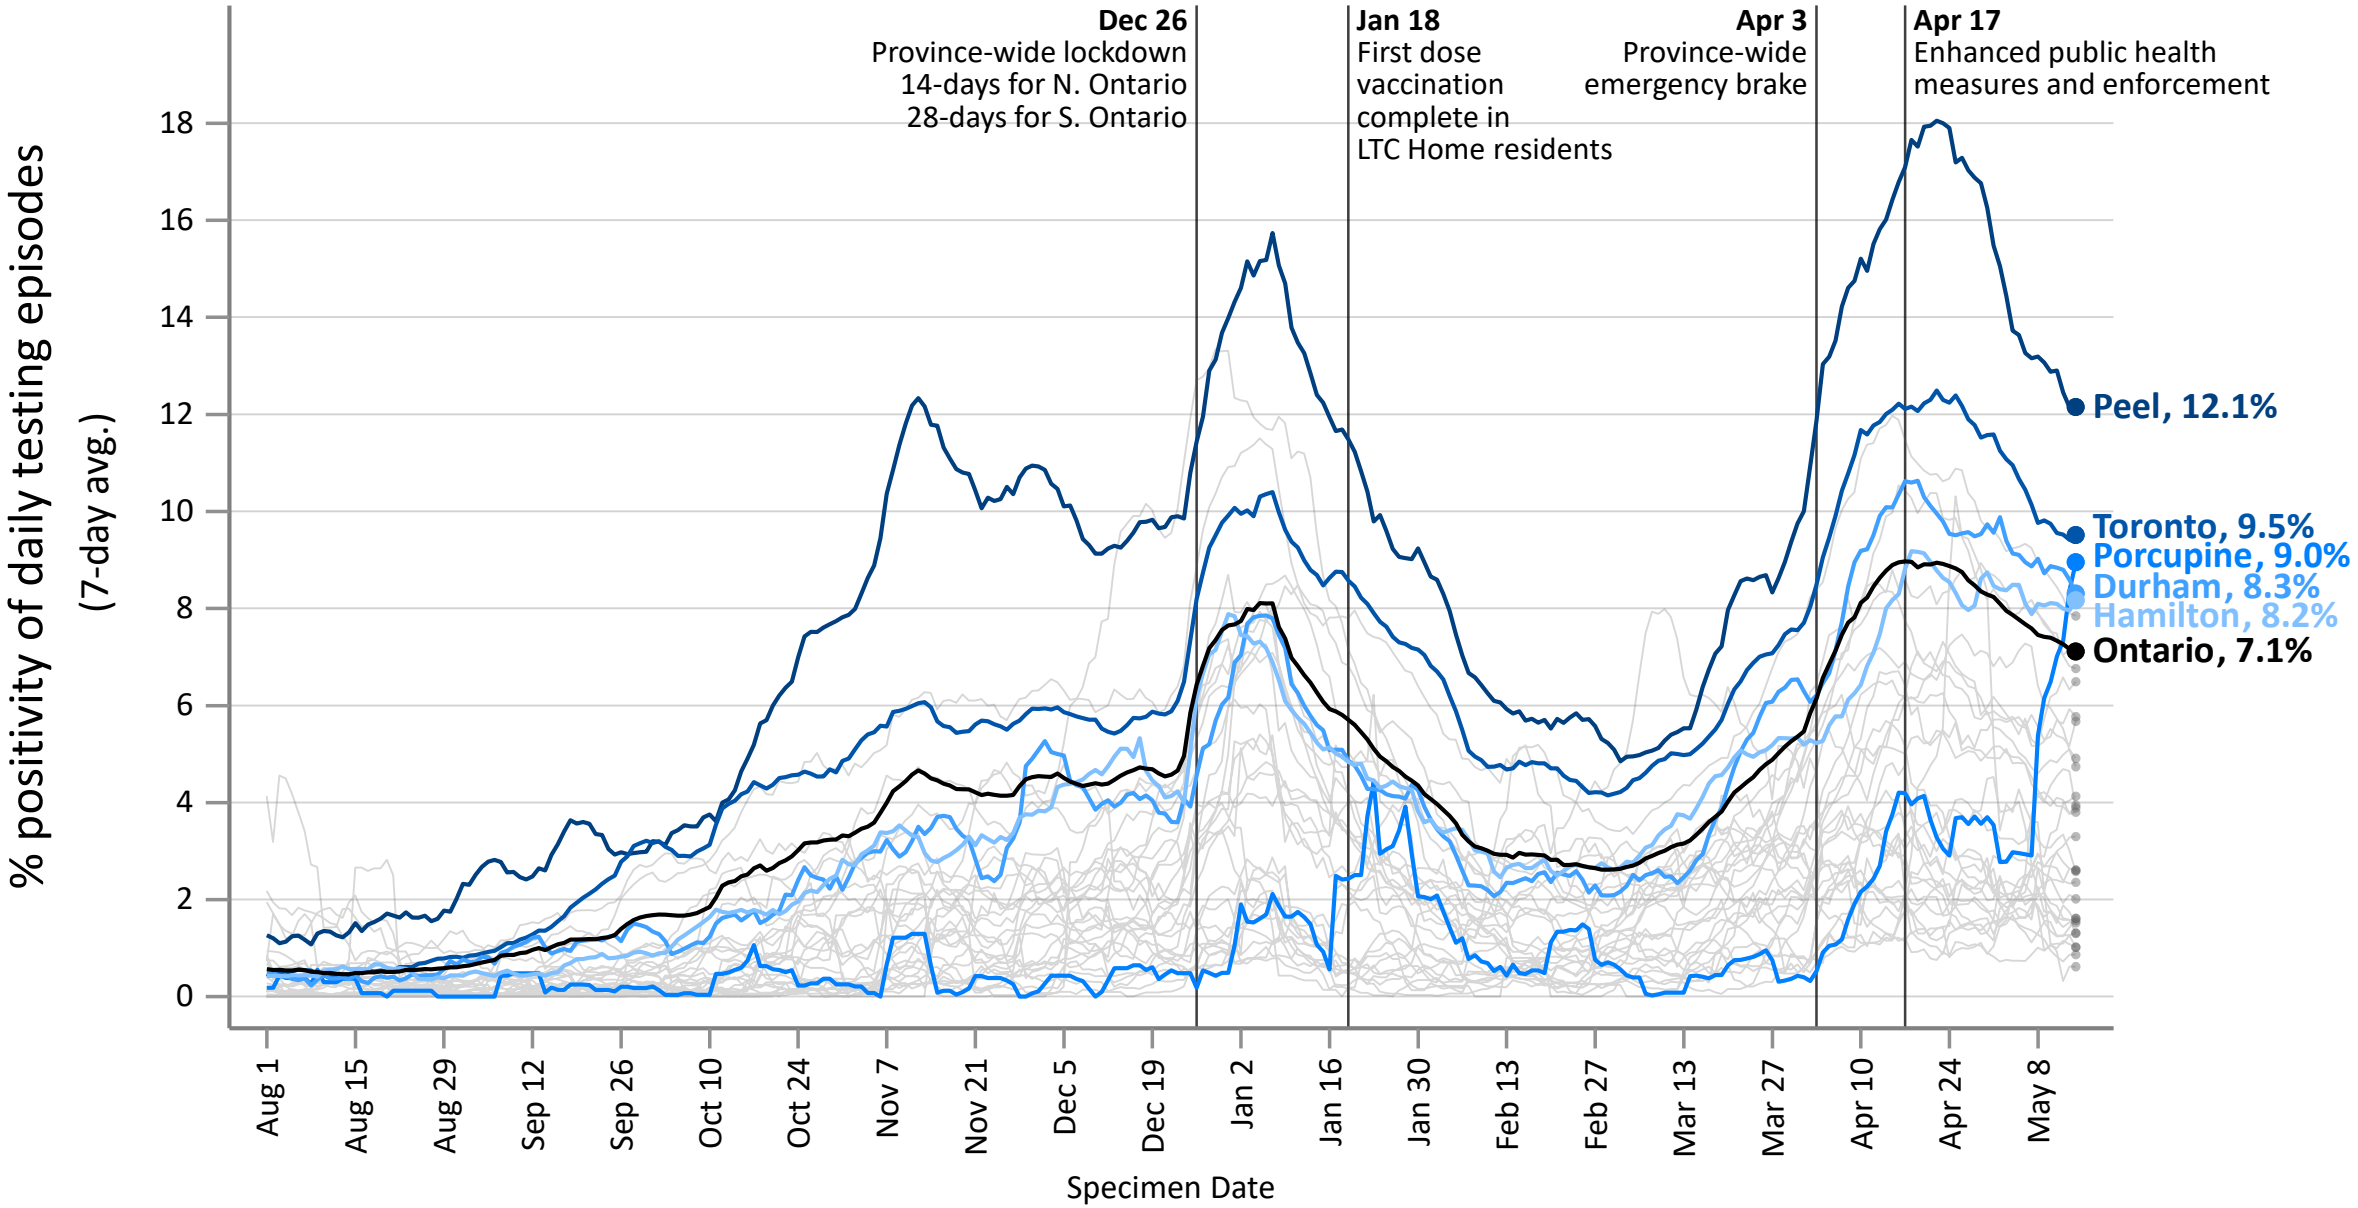
- Cases, positivity and hospitalization rates are decreasing. **Control of the pandemic is improving** due to current public health measures and the efforts of Ontarians.
- The access to care deficit continues but high-priority surgeries are being performed at higher rates.
- **Maintaining progress on vaccinations and maintaining some public health measures** until mid-June can help ensure a good summer:
  - School re-opening will create an increase in cases, but this may be manageable.
  - **Outdoor activities are much safer** than indoor activities and should be encouraged.

Cases are decreasing in most Public Health Units, with the greatest progress made in hotspot areas



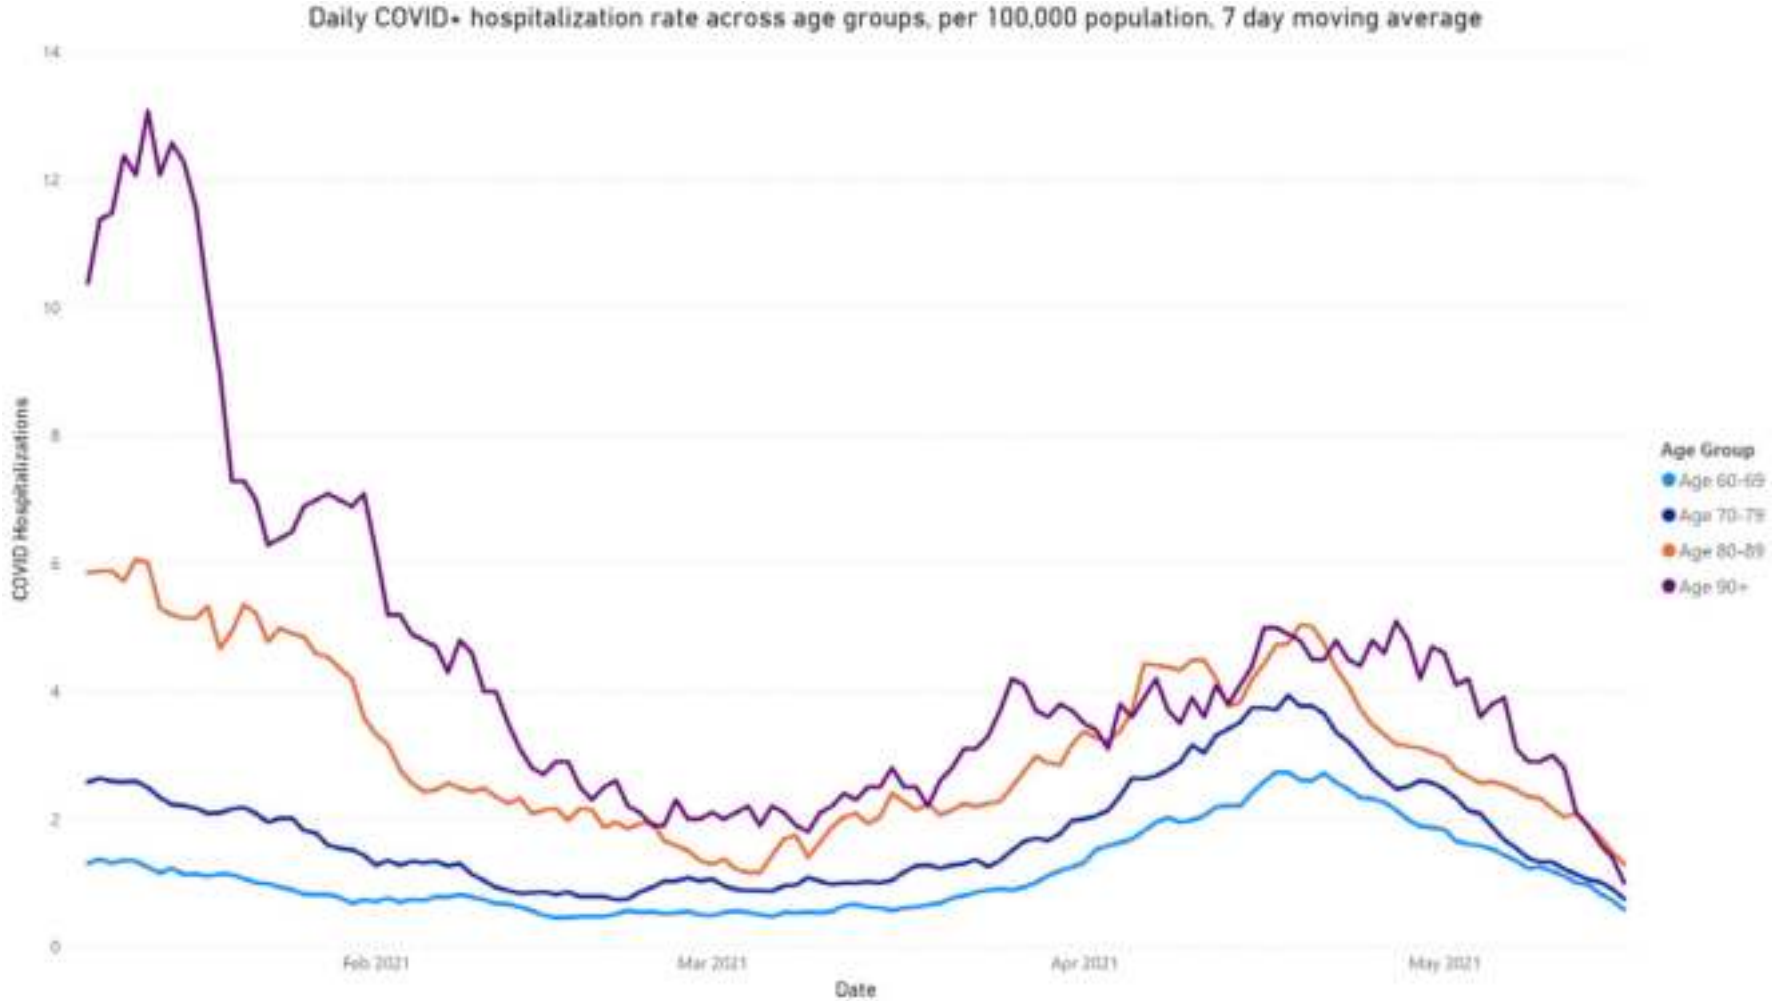
Data source: CCM
Data note: Data for the most recent day have been censored to account for reporting delays

% positivity is declining across Ontario

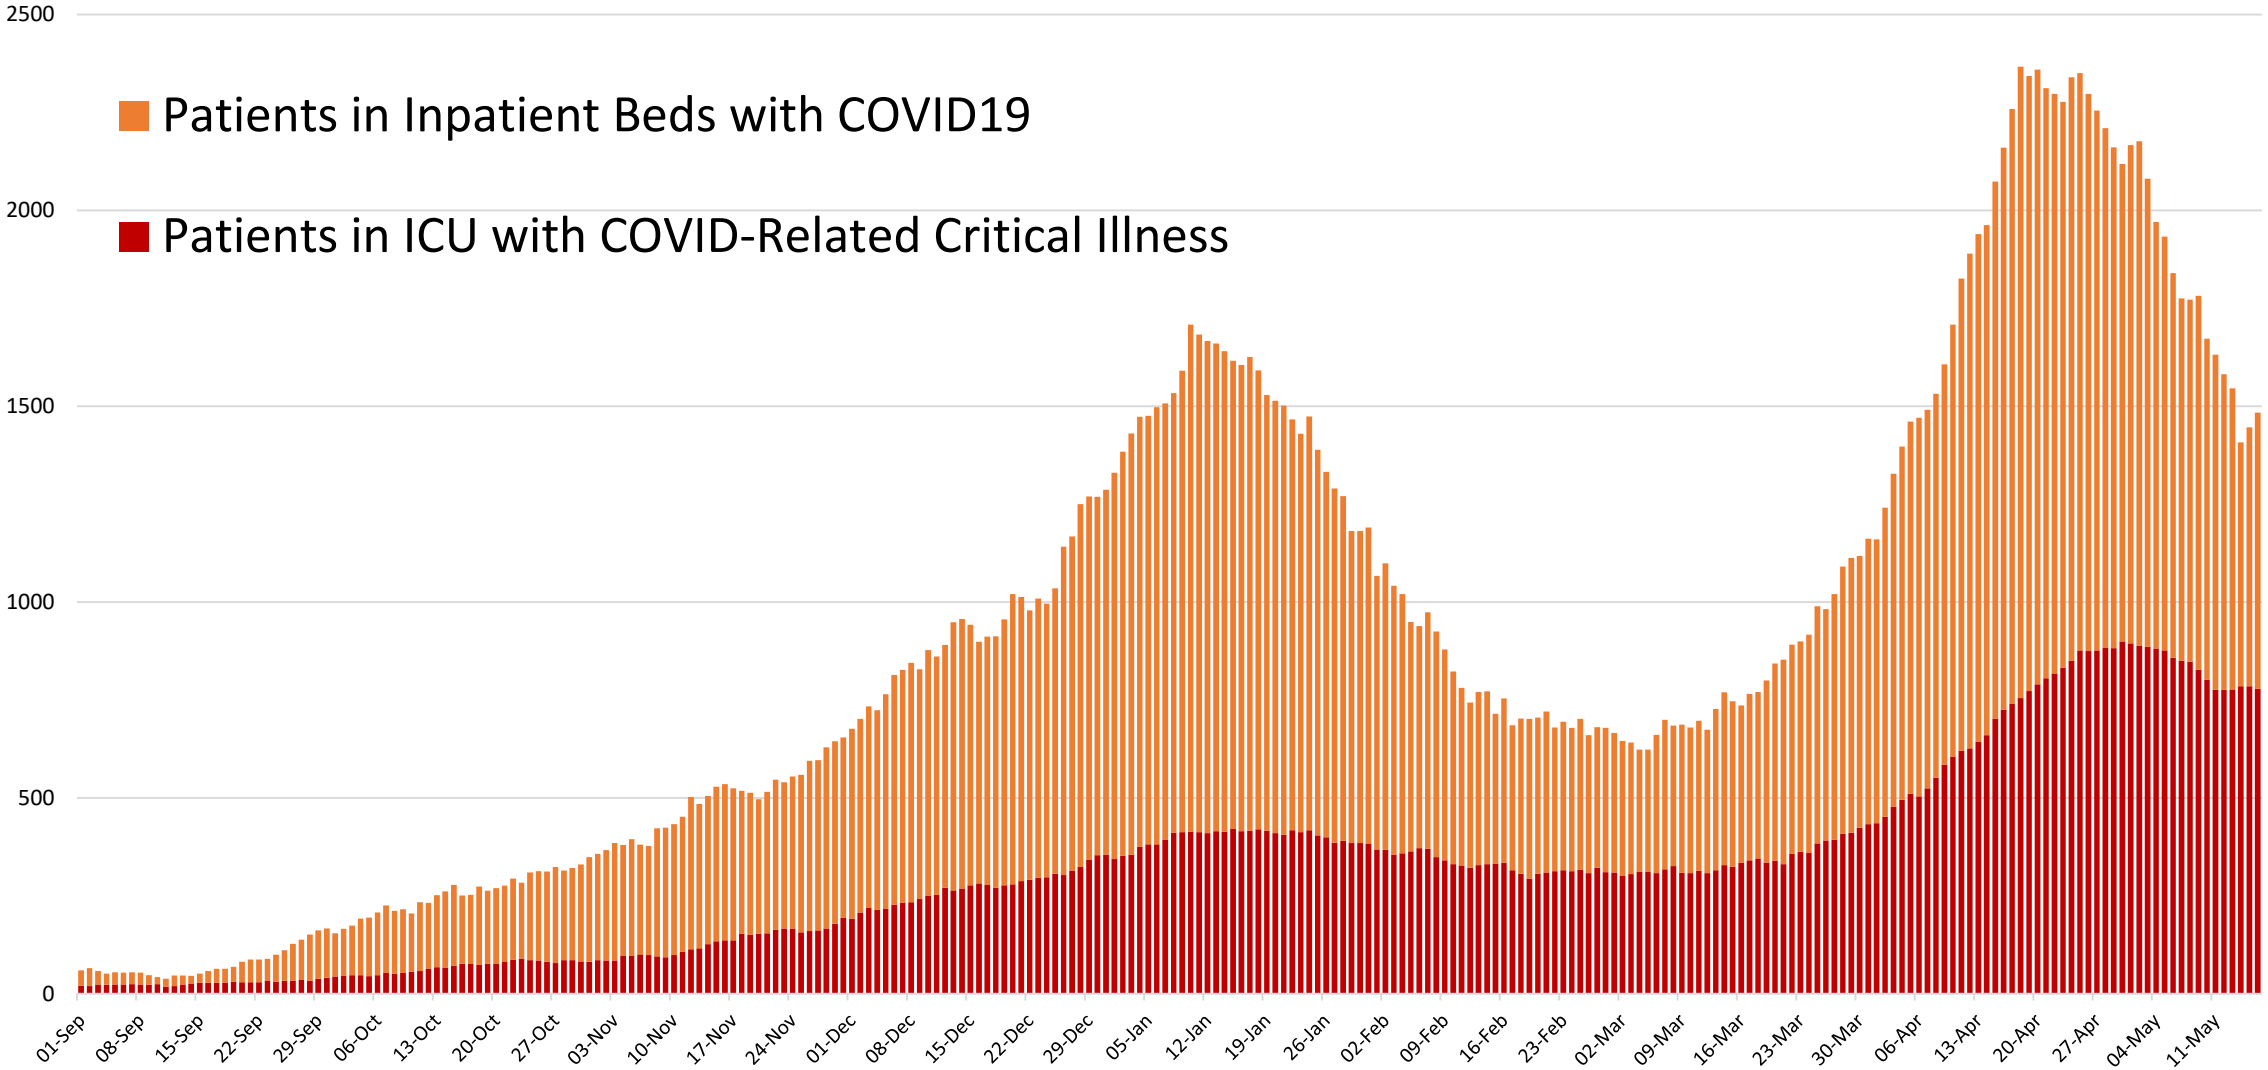


Data source: Ontario Laboratory Information System (OLIS), data up to May 14

Higher vaccination coverage is starting to control hospitalizations in older age groups



Hospitalization rates are down, ICU occupancy has dropped slightly



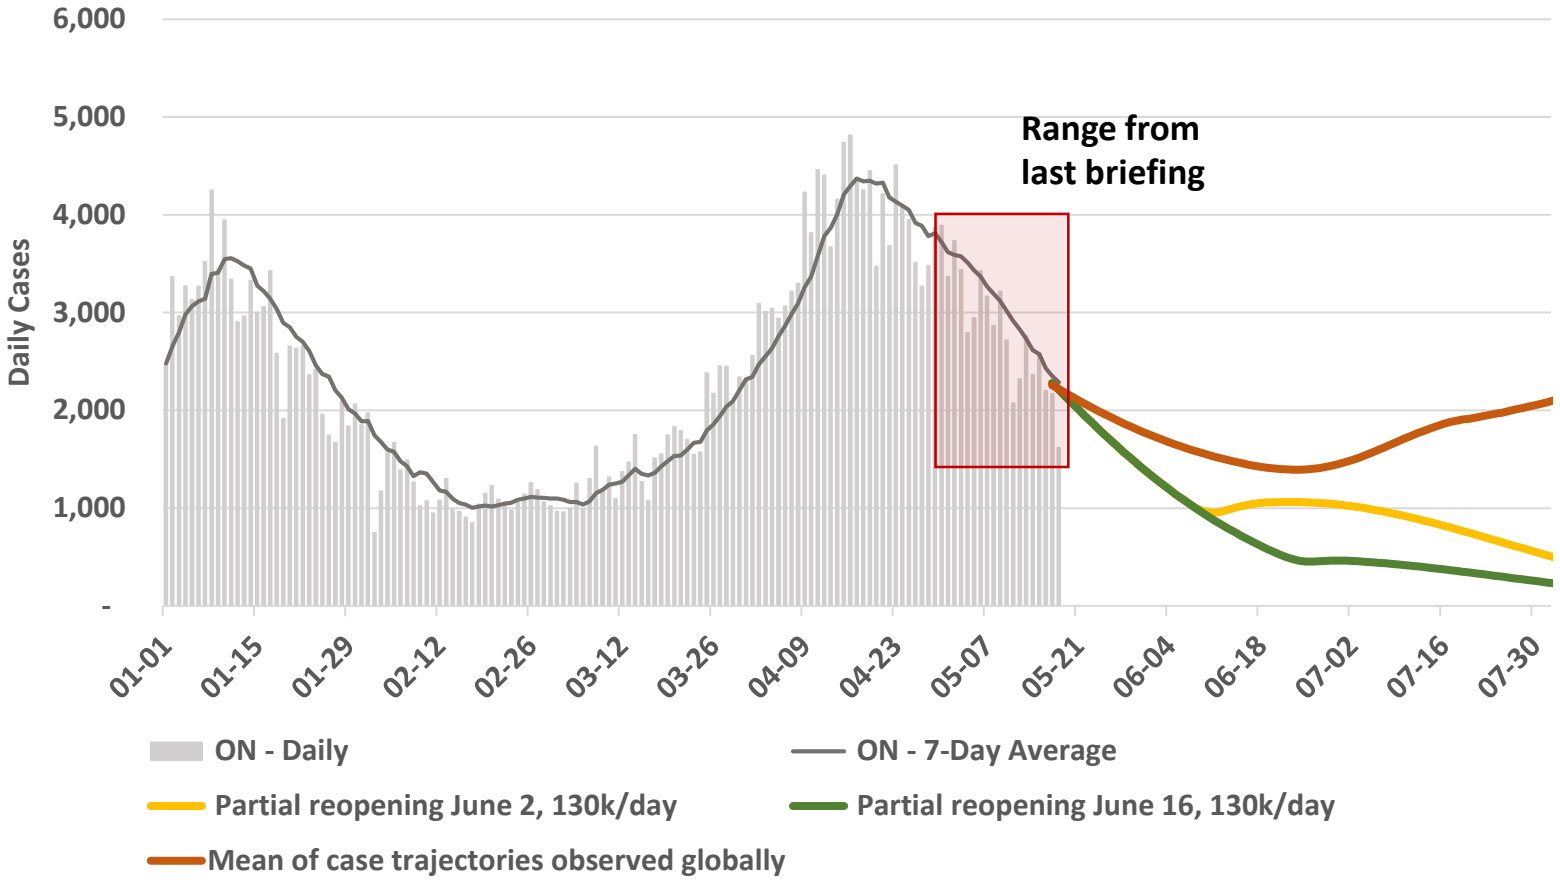
Data Sources: MOH COVID Inpatient Census and Critical Care Information System

Continued efforts to control spread of COVID-19 can help limit the impact of all variants of the virus

Figure shows predictions based on 5 models.

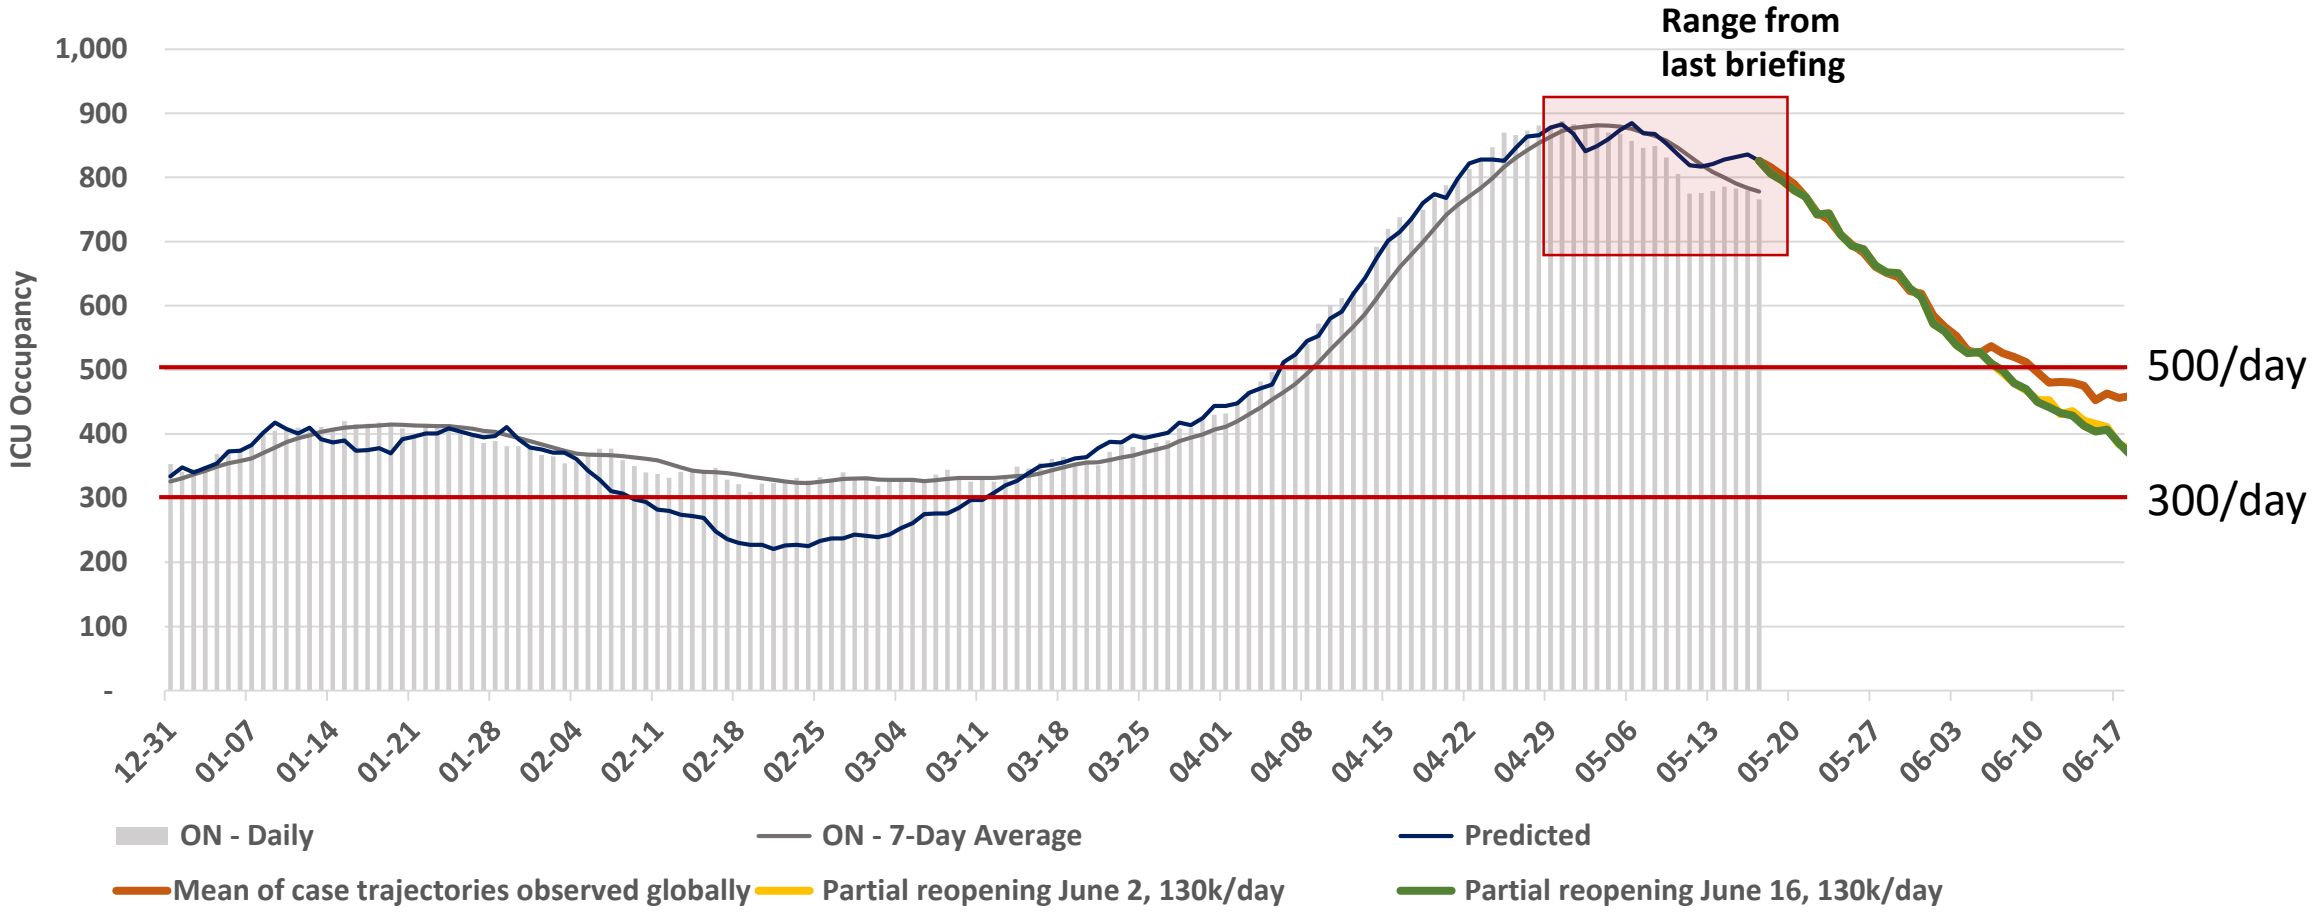
- Partial reopening June 2 or 16
- Vaccinating 100k-150k/day
- New VOC not explicitly considered

Not shown: 2 models looked at school opening June 2: School opening associated with a 6-11% increase in new daily cases



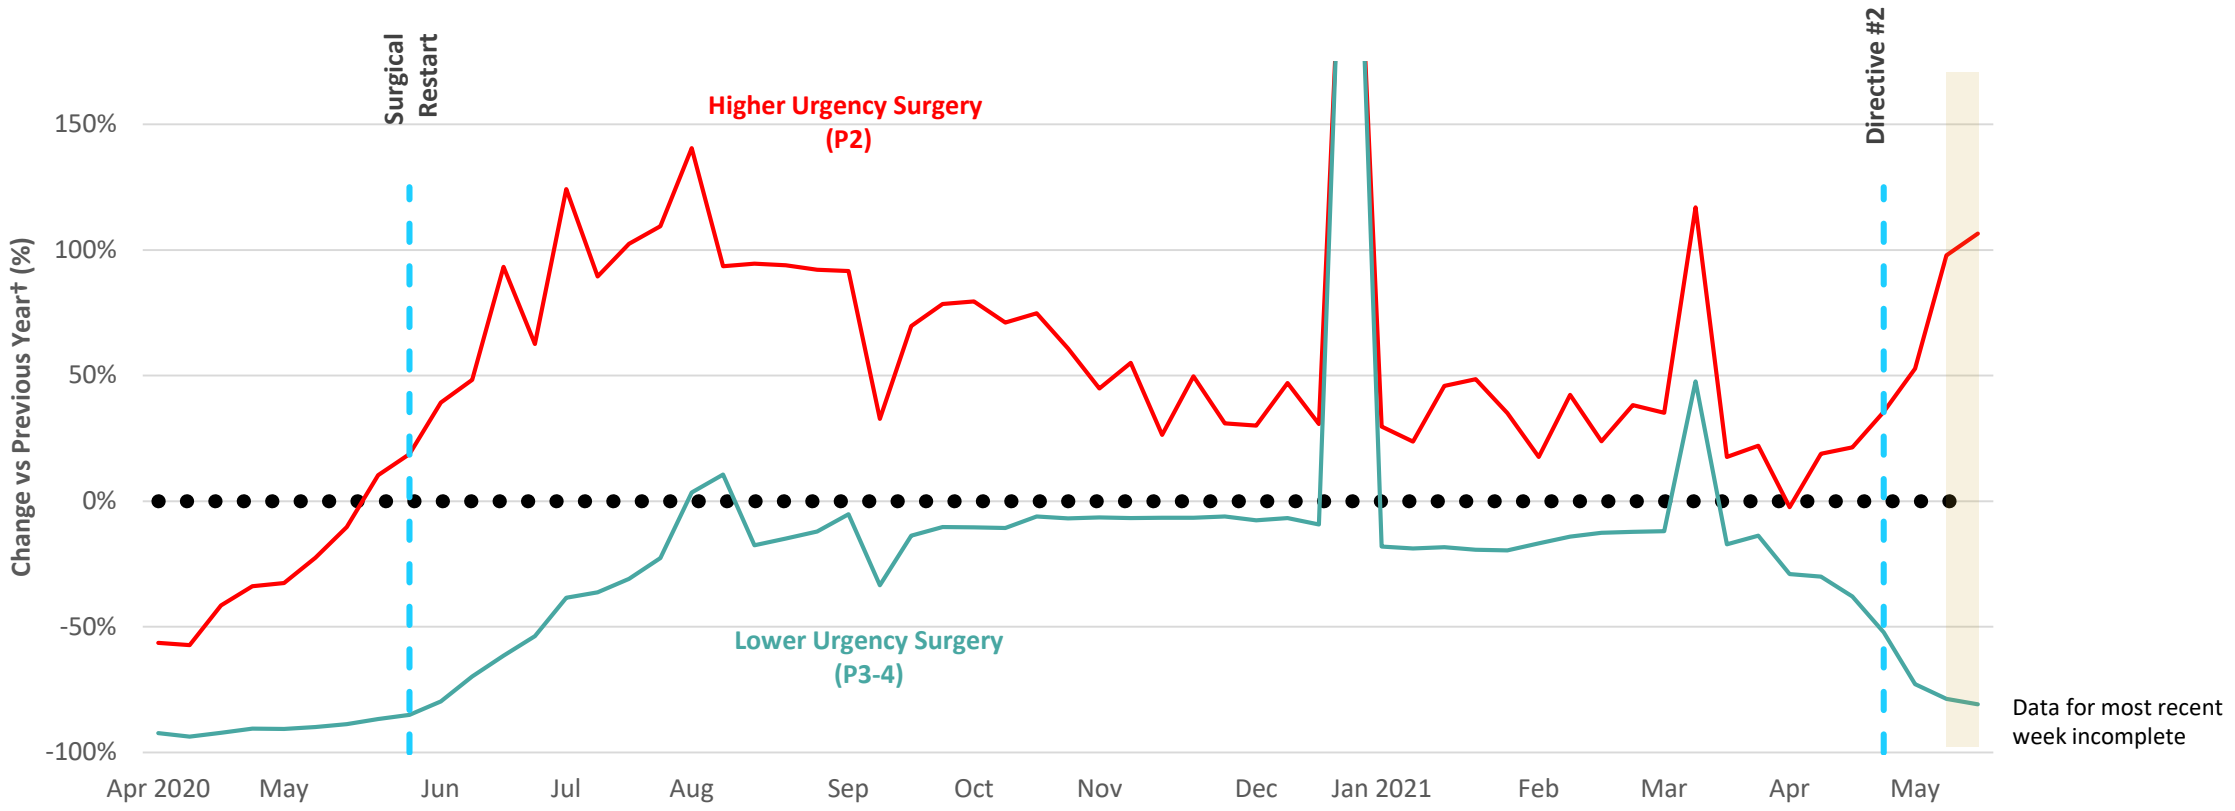
Predictions informed by modeling from COVID-19 ModCollab, Fields Institute, McMasterU, PHO, YorkU
Data (Observed Cases): covid-19.ontario.ca

ICU occupancy continues to decrease slowly, with potentially fewer than 500 patients with COVID-19 in ICUs by mid-June



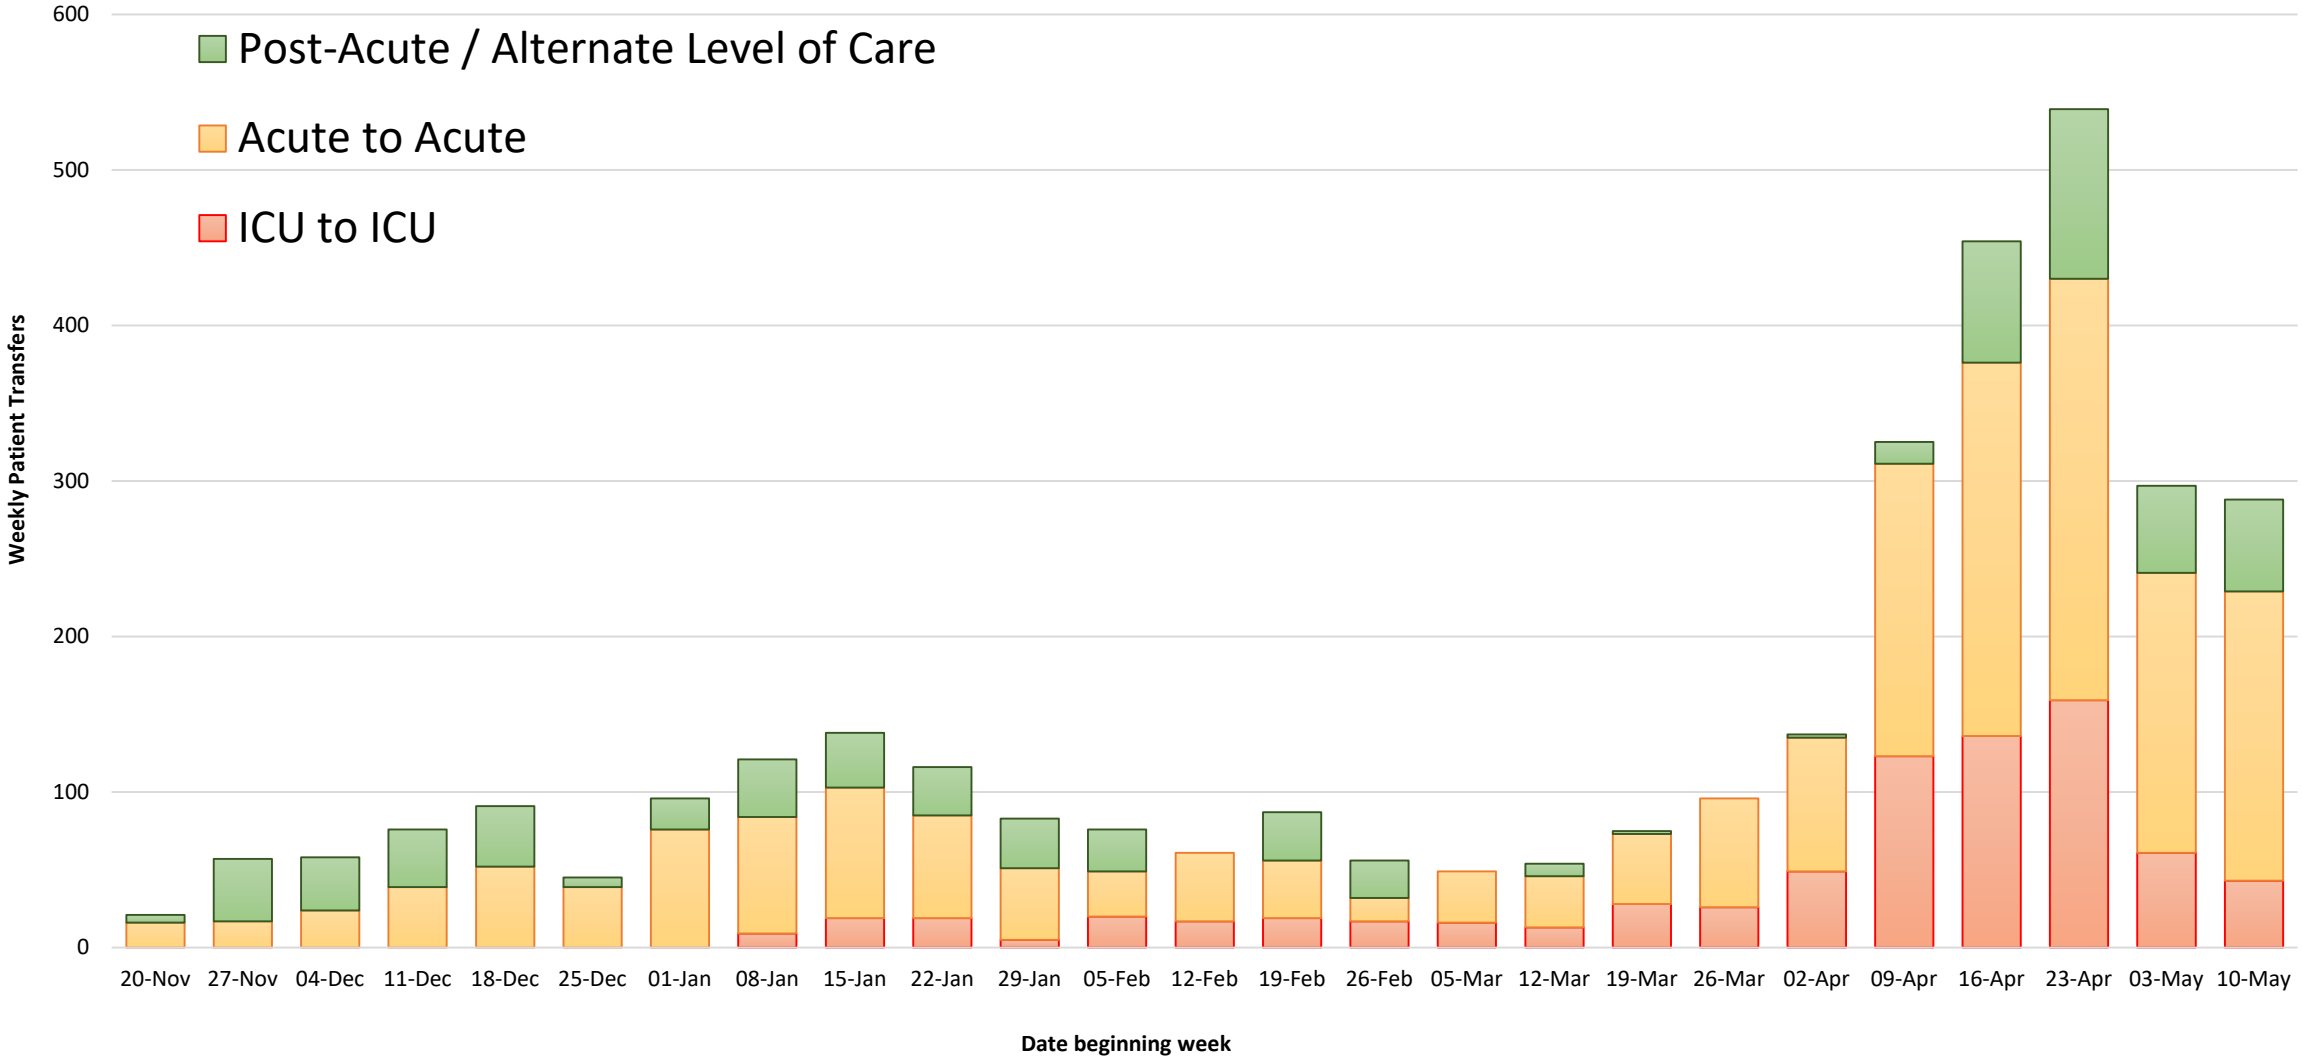
Predictions: COVID-19 ModCollab.
Data (Observed ICU Occupancy): CCSO

Higher priority procedures were more likely to be completed throughout the pandemic



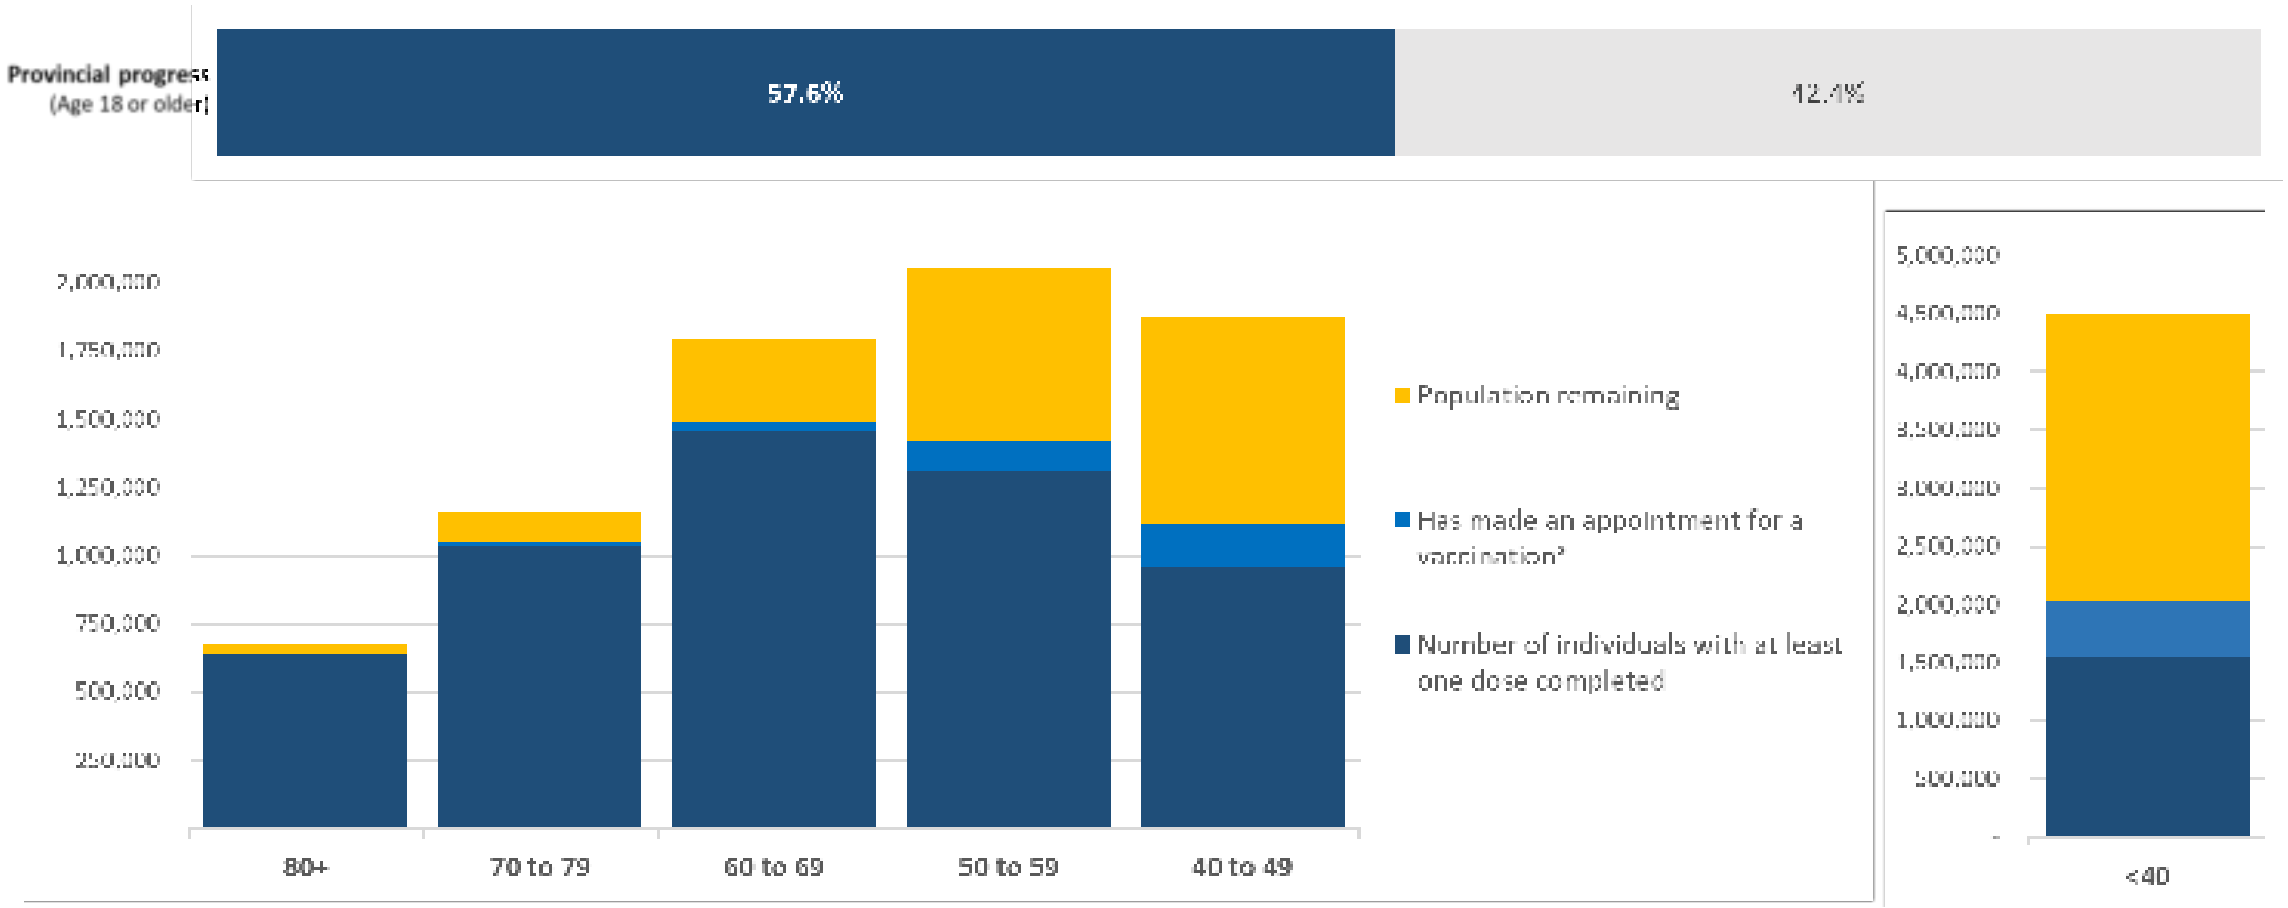
† As of the week of March 8, 2021, the comparator year was rolled back to 2019 to ensure the baseline for comparison continues to be pre-pandemic data

While the situation is improving, a high volume of patient transfers continues due to system capacity pressures



Data Sources: GTA IMS Transport Tracking, Ontario Health

Vaccination coverage continues to increase



* Note that this is just *Pending Appointments*. Anyone that has made an appointment and received a vaccine will be counted under "Individuals with at least one dose". Data for Appointments reflect 21 PHUs that are captured through the provincial booking system. Appointments made through other systems (e.g., local PHU booking systems, pharmacies, primary care) are not included.
Age is based on year of birth. Age <40 includes those age 18-39. Figure for age <40 is shown separately because of the difference in scale of the overall population size.

Data Sources
MOF 2020 Population Projections
COVAX analytical file, extracted, 8:00 pm May 18 2021, CPAD, MOH
COVAX Skedulo, extracted 6:00pm May 18 2021

The hotspot strategy is working. Continued efforts are key to a good summer.

Figure excludes long-term care vaccination – at least 1 dose as of May 17, 2021

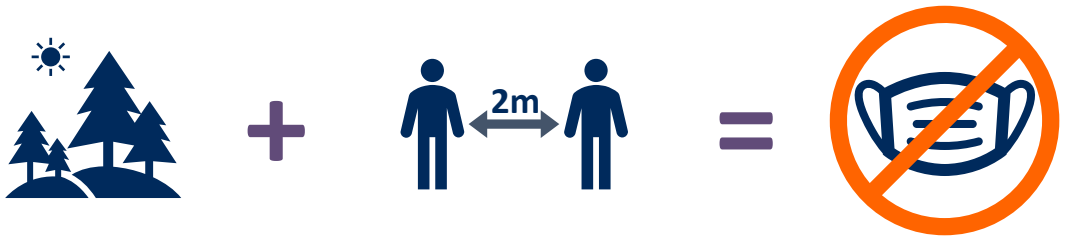
Outdoor activities can be much safer

Two-out-of-three rule for outdoor activities

Outdoors + Distance = No Masks Needed



Outdoors + No Distance = Masks Needed

Always wear masks and distance indoors

Byproducts to avoid when engaging in outdoor activities

Dining indoors, dining with others, sharing food or drinks

Crowding and going to crowded places

Carpooling with others

Travel between regions

Sharing overnight accommodation with others

Locker rooms and shared amenities

Marr L, Virginia Tech 2021

Select examples of safer outdoor activities

Camping

- Local camping with your own household is safer
- Camping elsewhere with your own household is not safer
- Camping with people outside your household is not safer

Basketball

- Basketball with masks is safer

Tennis

- Single tennis is safer
- Doubles tennis with masks is safer

Singing and playing music

- Singing outside where there is social distancing is safer

Note: Indoor facilities associated with outdoor recreation (e.g., change rooms and clubhouses) present a greater risk and should remain closed at this time

Key Findings

- Cases, positivity and hospitalization rates are decreasing. **Control of the pandemic is improving** due to current public health measures and the efforts of Ontarians.
- The access to care deficit continues but high-priority surgeries are being performed at higher rates.
- **Maintaining progress on vaccinations and maintaining some public health measures** until mid-June can help ensure a good summer:
  - School re-opening will create an increase in cases, but this may be manageable.

A Commissioner for the Taking of Affidavits

INSTRUCTIONS FROM THE MEDICAL OFFICER OF HEALTH

DATE: Thursday June 10, 2021 **EFFECTIVE:** Friday, June 11, 2021 at 12:01 a.m.

TO: All persons responsible for a business or organization **(workplace)** in the Porcupine Health Unit **(PHU)** region, where workers (including employees, those hired under third party agencies, contractors, vendors, volunteers or students and any other such persons) are present at the workplace or the public are regularly present.

First of all, I would like to thank you for your ongoing efforts to comply with public health requirements that aim to protect your staff, patrons and other members of our community. I would like to thank you for your strong commitment to encourage workers to receive their vaccinations against COVID-19.

As much as we have achieved by working together in the face of this pandemic, at this time, I must ask for your continued patience and support in the interests of protecting the health of our community.

While our vaccination rates are strong and growing daily, other trends in public health and health system indicators are very concerning:

- Our data reflects that Porcupine Health Unit has one of the highest rates of COVID-19 transmission in the province, with approximately 300 cases per 100,000 for the past 3 weeks;
- There have been multiple COVID-19 outbreaks across the region, including in workplaces and remote communities with limited access to health care services;
- The surge in cases in our community has affected health care and public health capacity, requiring additional support from other health units as well as the Ontario Ministry of Health's Provincial Work Force;
- We have clear evidence that the Delta variant – significantly more transmissible than the B.1.1.7 variant – is circulating in our region - with cases confirmed so far in Timmins. The Province has identified Porcupine as one of the seven health unit regions where the delta variant is of concern.

These trends are worrisome and require extreme caution as we move to lift public health measures. Some municipalities and First Nation communities have already responded to these developments by declaring a state of emergency.

Head Office:
169 Pine Street South
Postal Bag 2012
Timmins, ON P4N 8B7

E-mail: info4you@porcupinehu.on.ca
Web site: www.porcupinehu.on.ca

Branch Offices: Cochrane, Hearst, Hornepayne, Iroquois Falls, Kapuskasing, Matheson,
Moosonee, Smooth Rock Falls

With strong support from Ontario's Chief Medical Officer of Health, who recognizes the need for an approach tailored to the Porcupine Health Unit's unique circumstances, we will therefore be taking more gradual approach to reopening starting on June 11, 2021 at 12:01 a.m.

While operating under some of the new provincial Step 1 Rules immediately, we must maintain some Shutdown-level restrictions to minimize the person-to-person interactions that are fueling uncontrolled transmission of COVID-19 within our communities.

I anticipate these continued Shutdown-level restrictions will remain necessary for no longer than the next two weeks, remaining in place until June 25, 2021 at 12:01 a.m. I will regularly assess our progress against key public health and health system indicators and will report publicly on our progress.

Ontario's new Step 1 Rule continue to require persons responsible for a business or organization that is open to operate the business or organization in compliance with the instructions of public health officials. This includes the following instructions issued by me in this document.

These instructions will be enforced by provincial offences officers and public health officials under one or more of the *Health Protection and Promotion Act*, *Reopening Ontario (A Flexible Response to COVID-19) Act, 2020* and/or the *Emergency Management and Civil Protection Act*. Failure to comply is a provincial offence. Among enforcement actions that may be taken, you may be charged, and penalties imposed including fines, imprisonment and/or closure of premises.

Should you have any questions, please do not hesitate to contact the Porcupine Health Unit at 1-800-461-1818 or visit our website: https://www.porcupinehu.on.ca/en/your-health/infectious-diseases/novel-coronavirus/covid-orders/covid-moh-instructions/.

.

These instructions remain in effect until amended or rescinded by me.

ENSURE STRICT COMPLIANCE WITH ALL STEP 1 RULES AND INSTRUCTIONS THAT APPLY

1. You must familiarize yourself with all Step 1 Rules and instructions that apply to your workplace and ensure strict compliance with them, at all times, by workers and members of the public present at the workplace.

2. Ontario's Step 1 Rules are contained at Schedules 6 through 10 of Ontario Regulation 82/20 and may be accessed at: https://www.ontario.ca/page/emergency-information. The Shutdown Rules are contained at Schedules 1 through 5 of this same regulation.

3. Until more positive trends in key public health and health system indicators are demonstrated in the PHU region, the instructions set out in paragraphs 5 to 39 below continue some Shutdown-level requirements, maintaining a higher level of restriction than the Step 1 Rules. For greater certainty, nothing in the Step 1 Rules or in these instructions precludes any business or organization from:

    a) providing goods by mail or other forms of delivery or making goods available for pick-up; and
    b) providing services online, by telephone or by other remote means.[1]

[1] See Step 1 Rules, section 1(7), Schedule 6, O. Reg. 82/20

4. **Physical distancing and masks or face coverings in lines, etc.** In addition to the requirements of section 5, Schedule 6, O. Reg. 82/20, the person responsible for a business or place that is open must not permit patrons to line up or congregate outside of the business or place, unless they are both,

    a) maintaining a physical distance of at least two metres from other groups of persons; and
    b) wearing a mask or face covering in a manner that covers their mouth, nose and chin, unless they are entitled to any of the exceptions set out in subsection 2(5) Schedule 6, O. Reg. 82/20.[2]

5. **Sale and service of liquor.**

    a) The person responsible for a business or place that is open and in which liquor is sold or served under a licence or a special occasion permit shall ensure that,
        i. liquor is sold or served only between 9 a.m. and 9 p.m.; and
        ii. no consumption of liquor is permitted in the business or place between the hours of 10 p.m. and 9 a.m.
    b) The conditions set out in subsection a) do not apply with respect to businesses and places in airports.
    c) The conditions set out in subsection a) do not apply with respect to,
        i. the sale of liquor for removal from licensed premises in accordance with section 56.1 of Regulation 719 (Licences to Sell Liquor) made under the Liquor Licence Act; and
        ii. the sale of liquor for delivery in accordance with section 56.2 of Regulation 719 (Licences to Sell Liquor) made under the *Liquor Licence Act*.

6. **Discount and big box retailers selling groceries.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, discount and big box retailers that engage in retail sales to the public must meet the following conditions:

    a) The discount or big box retailer sells groceries to the public.
    b) In-store shopping must only be available for grocery items, pet care supplies, household cleaning supplies, pharmaceutical items, health care items, school supplies, household safety supplies and personal care items.
    c) No other goods or services may be sold to the public unless the discount or big box retailer complies with any conditions that are applicable with respect to the sale of those goods or services by other retail establishments under the Step 1 Rules as modified by these instructions (e.g., to exclude in-store shopping for non-essential retail etc.).[3]

7. **Safety supply stores.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, safety supply stores must meet the following conditions:

    a) They must only permit members of the public to enter the business premises by appointment.
    b) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[4]

[2] See Shutdown Rules, section 4, Schedule 1, O. Reg. 82/20
[3] See Shutdown Rules, section 3(1), Schedule 2, O. Reg. 82/20
[4] See Shutdown Rules, section 4(2), Schedule 2, O. Reg. 82/20

8. **Businesses that primarily sell, rent or repair assistive devices, aids or supplies, mobility devices, aids or supplies or medical devices, aids or supplies.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, these businesses must meet the following conditions:

    a) They must only permit members of the public to enter the business premises by appointment.
    b) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[5]

9. **Optical stores that sell prescription eyewear to the public.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, these stores must meet the following conditions:

    a) They must only permit members of the public to enter the business premises by appointment.
    b) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[6]

10. **Retail stores operated by telecommunications providers.** In addition to the requirements of sections 2 and 30, Schedule 7, O. Reg. 82/20, these stores must meet the following conditions:

    a) They must only permit members of the public to enter the premises by appointment and only for the purchase of cell phones, for repairs or for technical support.
    b) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[7]

11. **Stores, other than establishments described in section 3, Schedule 7, O. Reg. 82/20, that sell liquor, including beer, wine and spirits.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, these stores must meet the following condition:

    a) They must open no earlier than 7:00 a.m. and close no later than 8 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[8]

12. **Outdoor garden centres and plant nurseries.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, outdoor garden centres and plant nurseries must meet the following condition:

    a) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[9]

13. **Indoor greenhouses.** In addition to the requirements of section 2, Schedule 7, O. Reg. 82/20, indoor greenhouses must meet the following condition:

    a) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[10]

[5] See Shutdown Rules, section 4(2), Schedule 2, O. Reg. 82/20
[6] See Shutdown Rules, section 4(2), Schedule 2, O. Reg. 82/20
[7] See Shutdown Rules, section 33, Schedule 2, O. Reg. 82/20
[8] See Shutdown Rules, section 5, Schedule 2, O. Reg. 82/20
[9] See Shutdown Rules, section 9.1, Schedule 2, O. Reg. 82/20
[10] See Shutdown Rules, section 9.2, Schedule 2, O. Reg. 82/20

14. **Restaurants, bars, food trucks, concession stands and other food or drink establishments.** In addition to the requirements of section 3, Schedule 7, O. Reg. 82/20, establishments other than those described in subsection (3) may open only for the purpose of providing take-out, drive-through or delivery service.[11]

15. **Nightclubs and strip clubs that open solely as food or drink establishments.** In addition to the requirements of section 4, Schedule 7, O. Reg. 82/20, these nightclubs and strip clubs may open only for the purpose of providing take-out, drive-through or delivery service.[12]

16. **Shopping malls.** In addition to the requirements of section 5, Schedule 7, O. Reg. 82/20, shopping malls must meet the following conditions:

    a) Members of the public must only be permitted to enter the shopping mall for the purpose of accessing a business or place that is permitted to be open under the Step 1 Rules as modified by these instructions.
    b) Subject to subparagraph c), the shopping mall must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.
    c) A shopping mall may open outside of the hours described in subparagraph b) only for the purpose of providing access for members of the public to a business or place that,
        i. is permitted to open during those hours under the Step 1 Rules as modified by these instructions; and
        ii. only has public entrances that open into the interior of the shopping mall.
    d) For greater certainty, section 8(2) paragraph 5 of Schedule 7, O. Reg. 82/20 does not prevent a restaurant, bar or other food or drink establishment within a shopping mall from opening and operating in compliance with section 3 of Schedule 7 as modified by these instructions.[13]

17. **Fitting rooms in a business.** Fitting rooms in a business may open if patrons are not permitted to occupy adjacent fitting room stalls at any one time.[14]

18. **Businesses that sell motor vehicles etc.** These requirements apply to businesses that sell:

    - Motor vehicles, including cars, trucks and motorcycles;
    - Recreational vehicles, including motor homes;
    - Trailers and travel trailers;
    - Boats and other watercraft; or
    - Other motorized vehicles, including power-assisted bicycles, golf carts, scooters, snowmobiles and all-terrain vehicles.

    In addition to the requirements of section 5.2, Schedule 7, O. Reg. 82/20, these businesses must meet the following conditions:

    a) Members of the public must only be permitted to enter the premises by appointment.

    b) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.

[11] See Shutdown Rules, section 6, Schedule 2, O. Reg. 82/20
[12] See Shutdown Rules, section 6, Schedule 2, O. Reg. 82/20
[13] See Shutdown Rules, section 8, Schedule 2, O. Reg. 82/20
[14] See Shutdown Rules, section 8.1, Schedule 2, O. Reg. 82/20

c) They must limit the number of persons in the place of business so that the total number of persons in the place of business at any one time does not exceed 25 per cent capacity, as determined in accordance with subsection 3(3) of Schedule 6.[15]

19. **Outdoor markets, including farmer's markets and holiday markets.** In addition to the requirements of section 6, Schedule 7, O. Reg. 82/20, these markets must meet the following conditions:

    a) Products must only be provided to patrons,
        i. in a manner that allows members of the public to remain in an outdoor area at all times, or
        ii. through an alternative method of sale that does not require patrons to enter the indoor area, such as curbside pick-up or delivery.
    b) The outdoor market must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[16]

20. **Other businesses engaging in retail sales to the public.** In addition to the requirements of section 7, Schedule 7, O. Reg. 82/20, these businesses must meet the following conditions:

    a) Sales must be exclusively made using an alternative method of sale that does not require patrons to enter the indoor area of the business, including curbside pick-up or delivery.
    b) If the business allows patrons to pick up items, it must,
        i. have a public entrance that opens onto a street or exterior sidewalk, or
        ii. in the case of a business in a shopping mall, permit patrons to pick up the items at a designated location established by the shopping mall under subsection 8 (3) or (4).
    c) An item may only be provided for pick-up if the patron ordered the item before arriving at the business premises.
    d) Patrons may only pick up orders by making a prior appointment.
    e) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.
    f) Despite anything else in the Step 1 Rules, any business that engages in retail sales to the public and that is not already described in sections 1 to 6 of Schedule 7, must comply with the conditions set out in subsection 7(1) as modified by these instructions.
    g) Cannabis retail stores operating under the authority of a retail store authorization issued under the *Cannabis Licence Act, 2018* may open if they comply with the conditions set out in subsection 7(1) as modified by these instructions.[17]

21. **Rental and leasing services.** Further to section 8, Schedule 7, O. Reg. 82/20, rental and leasing services including automobile, commercial and light industrial machinery and equipment rental must meet the following conditions:

    a) They only permit members of the public to enter the business premises by appointment.
    b) They limit the number of persons in the place of business so that the total number of persons in the place of business at any one time does not exceed 25 per cent capacity, as determined in accordance with subsection 3 (3) of Schedule 6.

[15] See Shutdown Rules, section 9, Schedule 2, O. Reg. 82/20
[16] See Shutdown Rules, section 10, Schedule 2, O. Reg. 82/20
[17] See Shutdown Rules, section 10.1, Schedule 2, O. Reg. 82/20

c) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[18]

22. **Vehicle and equipment repair, essential maintenance etc.** Further to section 15, Schedule 7, O. Reg. 82/20, vehicle and equipment repair and essential maintenance and vehicle and equipment rental services must meet the following conditions:

    a) They only permit members of the public to enter the business premises by appointment.
    b) They limit the number of persons in the place of business so that the total number of persons in the place of business at any one time does not exceed 25 per cent capacity, as determined in accordance with subsection 3 (3) of Schedule 6.
    c) They must open no earlier than 7:00 a.m. and close no later than 8:00 p.m. and must not deliver goods to patrons outside of the hours of 6:00 a.m. to 9:00 p.m.[19]

23. **Child care providers.** For greater certainty further to section 21, Schedule 7, O. Reg. 82/20, the term "child care providers" includes but is not limited to operators and providers of the following:

    a) Child care centres that meet the conditions set out in subsection 21(2) of Schedule 7.
    b) Home child care at a person's dwelling.
    c) Child care described in paragraph 2 of subsection 6 (3) of the *Child Care and Early Years Act, 2014* that is provided at a person's dwelling.
    d) Authorized recreational and skill building programs that meet the conditions set out in subsection 21(3) of Schedule 7.[20]

24. **Businesses providing short term rental accommodation.** In addition to the requirements of section 21.1, Schedule 7, O. Reg. 82/20, businesses providing short term rental accommodation (including cabins and cottages but excluding hotels, motels, lodges, resorts and other shared rental accommodation including student residences) shall ensure that any rentals are only provided to individuals who are in need of housing.[21]

25. **Campgrounds.** In addition to the requirements of section 23, Schedule 7, O. Reg. 82/20, campgrounds must meet the following conditions:

    a) Campsites must be made available only for trailers and recreational vehicles that,
        i. are used by individuals who are in need of housing, or
        ii. are permitted to be there by the terms of a full season contract.
    b) Only campsites with electricity, water service and facilities for sewage disposal may be provided for use.
    c) All recreational facilities in the campground and all other shared facilities in the campground, other than washrooms and showers, must be closed.
    d) Other areas of the seasonal campground must be closed to the general public and must only be opened for the purpose of preparing the seasonal campground for reopening.[22]

[18] See Shutdown Rules, section 11, Schedule 2, O. Reg. 82/20
[19] See Shutdown Rules, section 18, Schedule 2, O. Reg. 82/20
[20] See Shutdown Rules, section 24, Schedule 2, O. Reg. 82/20
[21] See Shutdown Rules, section 6, Schedule 2, O. Reg. 82/20
[22] See Shutdown Rules, section 26, Schedule 2, O. Reg. 82/20

26. **Day camps for children.** Further to section 15, Schedule 7, O. Reg. 82/20, day camps for children must not provide in-person activities or services.[23]

27. **Construction.** Further to section 40, Schedule 7, O. Reg. 82/20, construction activities or projects and related services, including land surveying and demolition services continue to be restricted to those that:

    a) are associated with the health care sector or long-term care, including new facilities, expansions, renovations and conversion of spaces that could be repurposed for health care space;
    b) ensure safe and reliable operations of, or provide new capacity in,
        i. municipal infrastructure, or
        ii. provincial infrastructure, including but not limited to, the transit, transportation, resource, energy and justice sectors;
    c) support the operations of, or provide new capacity in, electricity generation, transmission, distribution and storage, natural gas distribution, transmission and storage or in the supply of resources;
    d) support the operations of, or provide new capacity in, schools, colleges, universities or child care centres within the meaning of the Child Care and Early Years Act, 2014;
    e) are required for,
        i. the maintenance and operations of petrochemical plants and refineries,
        ii. significant industrial petrochemical projects where preliminary work commenced before April 17, 2021, or
        iii. industrial construction and modifications to existing industrial structures limited solely to work necessary for the production, maintenance or enhancement of personal protective equipment, medical devices such as ventilators and other identified products directly related to combatting the COVID-19 pandemic;
    f) would provide additional capacity in the production, processing, manufacturing or distribution of food, beverages or agricultural products;
    g) were commenced before April 17, 2021 and that would,
        i. provide additional capacity for businesses that provide logistical support, distribution services, warehousing, storage or shipping and delivery services,
        ii. provide additional capacity in the operation and delivery of Information Technology (IT) services or telecommunications services, or
        iii. provide additional capacity to, or enhance the efficiency or operations of, businesses that extract, manufacture, process and distribute goods, products, equipment and materials;
    h) support the operations of broadband internet and cellular technologies and services;
    i) are residential construction activities or projects and related services;
    j) prepare a site for an institutional, commercial, industrial or residential development, including any necessary excavation, grading, roads or utilities infrastructure;
    k) are necessary to temporarily close construction sites that have paused, or that are not active, to ensure ongoing public safety;
    l) are funded in whole or in part by,
        i. the Crown in right of Canada or in right of Ontario,
        ii. an agency of the Crown in right of Canada or in right of Ontario, or

[23] See Shutdown Rules, Schedule 2, O. Reg. 82/20

iii. a municipality;

m) are,

i. intended to provide shelter or supports for vulnerable persons or affordable housing, and

ii. being funded in whole or in part by, or are being undertaken by,
(A) the Crown in right of Canada or in right of Ontario,
(B) an agency of the Crown in right of Canada or in right of Ontario,
(C) a municipality,
(D) a service manager as defined the *Housing Services Act, 2011*,
(E) a registered charity within the meaning of the *Income Tax Act* (Canada), or
(F) a not-for-profit corporation; or

n) support the operations of, or provide new capacity for, veterinary facilities within the meaning of the *Veterinarians Act*.[24]

28. **Facilities for indoor or outdoor sports and recreational fitness activities.** In addition to the requirements of section 45, Schedule 7, O. Reg. 82/20, indoor or outdoor sports and recreational activities at indoor or outdoor sports and recreational fitness are restricted to those that meet the conditions set out in subsections 45(2), (3), (4) and (5) only. For greater certainty, no indoor or outdoor sports or recreational classes are permitted at any indoor or outdoor sport and recreational facilities.[25] See also paragraph 37 of these instructions, below.

29. **Personal physical fitness, etc.** Further to section 45.1, Schedule 7, O. Reg. 82/20, personal fitness and sports trainers must not provide in-person services.[26]

30. **Teaching and instruction.** Further to section 57.1, Schedule 7, O. Reg. 82/20, must not provide in-person services.[27]

31. **Commercial film and television production.** In addition to the requirements of section 63, Schedule 7, O. Reg. 82/20, commercial film and television production, including all supporting activities, must meet the following condition:

    a) Singers and players of brass or wind instruments must be separated from any other performers by plexiglass or some other impermeable barrier.[28]

32. **Commercial and industrial photography.** Further to section 63.1, Schedule 7, O. Reg. 82/20, retail photo studios must not provide in-person services.[29]

33. **Concert venues, theatres and cinemas.** Further to section 65, Schedule 7, O. Reg. 82/20, concert venues, theatres and cinemas must not engage in in-person activities for the purpose of rehearsing or performing a recorded or broadcasted concert, artistic event, theatrical performance or other performance. For

[29] See Shutdown Rules, section 66, Schedule 2, O. Reg. 82/20

greater certainty, drive-in or drive-through format movies, concerts, artistic events, theatrical performances or other performances are not permitted.[30]

34. **Outdoor tour and guide services.** Further to section 66, Schedule 7, O. Reg. 82/20, outdoor tour and guide services are not permitted to provide in-person services.[31]

35. **Public libraries.** In addition to the requirements of section 1, Schedule 8, O. Reg. 82/20, public libraries must meet the following condition:

    a) Circulating materials returned to the library must be disinfected or quarantined for an appropriate period of time before they are recirculated.[32]

36. **Schools and private schools.** In addition to the requirements of section 3, Schedule 8, O. Reg. 82/20, schools and private schools within the meaning of the *Education Act* must meet the following condition:

    a) the in-person activities addressed in subsection 3(5) are not permitted.[33]

37. **Indoor and outdoor recreational amenities.** In addition to the requirements of section 4, Schedule 8, O. Reg. 82/20, an outdoor recreational amenity described in subsection 4(2) must meet the following conditions:

    a) Team sports must not be practised or played within the amenity.
    b) Any locker rooms, change rooms, showers, clubhouses, restaurants, pools, meeting rooms, fitness centres or other recreational facilities on the premises must remain closed, except to the extent they provide access to equipment storage, a washroom or a portion of the amenity that is used to provide first aid.[34]

38. **Museums etc.** Further to section 5, Schedule 8, O. Reg. 82/20, museums, galleries, aquariums, zoos, science centres, landmarks, historic sites, botanical gardens and similar attractions must not provide in-person services.[35]

39. **Organized public events, gatherings.** In addition to the requirements of section 1, Schedule 9, O. Reg. 82/20, all businesses and organizations that are open are subject to the following conditions:

    a) They must not host, organize or otherwise participate in an organized public event or social gathering that is held indoors, including a public event or social gathering associated with a wedding, a funeral or a religious service, rite or ceremony even if it is held at a private dwelling.
    b) They must not host, organize or otherwise participate in an organized public event or social gathering of more than 5 people that is held outdoors, including a public event or social gathering associated with a wedding, a funeral or a religious service, rite or ceremony even if it is held at a private dwelling.

[30] See Shutdown Rules, Schedule 2, O. Reg. 82/20

Instructions from the Medical Officer of Health for Businesses and Workplaces (Moosonee): 2021-06-25

DATE: Wednesday June 23, 2021

EFFECTIVE: Friday, June 25, 2021 at 12:01 a.m.

TO:

All persons responsible for a business or organization **(workplace)** in the Town of Moosonee within the Porcupine Health Unit **(PHU)** region, where workers (including employees, those hired under third party agencies, contractors, vendors, volunteers or students and any other such persons) are present at the workplace or the public are regularly present.

Once again, I thank you for your ongoing efforts to comply with public health requirements that aim to protect your staff, patrons and other members of our community. I also thank you for your strong commitment to encourage workers to receive their vaccinations against COVID-19.

As much as we have achieved by working together in the face of this pandemic, however, I must ask for your continued support in the interests of protecting the health of our community. While our vaccination rates are strong and growing daily, other trends in public health and health system indicators are very concerning:

- A total of 1,353 confirmed COVID-19 cases have been reported between May 1st and June 21, 2021. Of these, 437 cases were reported in the James and Hudson Bay region.
- In May, 72 cases were reported from the James and Hudson Bay region (average of 2.3 cases per day) and 155 cases were reported between June 11th and June 17th (average of 22.1 cases per day) and 41 cases were reported between June 18th and June 22nd (average of 8.2 cases per day).
- PHU's overall infection rate increased by 278% from 93.5 per 100,000 on May 1 to a high of 353.5 per 100,000 on May 25. Since then, the rate has decreased but remains high at 101.9 per 100,000 on June 21, 2021.
- More cases have been confirmed for the Delta variant. As of June 22, 2021, a total of 30 Delta VOCs has been detected to date in the PHU area.
  - Of these 30 Delta VOCs, 28 were from the Timmins area, 1 from Iroquois Falls and 1 from Smooth Rock Falls.
  - These 30 Delta variants likely reflect only a tip of the iceberg. Because it is highly transmissible, more cases are expected as further results from tests in progress are received.
- A total of 63 confirmed COVID-19 cases in the PHU area have been hospitalized in the period since May 1.

- Thirty-three outbreaks have been declared in different settings since March 27, 2021, twenty of which are in workplaces resulting in 238 cases and 786 close contacts.

These trends are worrisome and require extreme caution and enhanced diligence with the public health measures as we move to lift the current restrictions.

Ontario's new Step 1 Rules that apply in the PHU Region continue to require persons responsible for a business or organization that is open to operate the business or organization in compliance with the instructions of public health officials. This includes the following instructions issued by me in this document.

Ontario's Chief Medical Officer of Health has recognized the need for an approach tailored to the PHU's unique circumstances, requiring a more gradual approach to reopening beginning on June 11, 2021. The Town of Moosonee, in particular, faces special challenges given its important role and connections with many remote communities – including but not limited to Moose Factory and 6 unique First Nation communities.

With strong support from leadership within the town of Moosonee and region I have therefore determined that some continued restrictions – set out in the instructions below – are needed for Moosonee as we move to reopen under Ontario's Step 1 Rules.

These instructions will be enforced by provincial offences officers and public health officials under one or more of the *Health Protection and Promotion Act, Reopening Ontario (A Flexible Response to COVID-19) Act, 2020 and/or the Emergency Management and Civil Protection Act.* Failure to comply is a provincial offence. Among enforcement actions that may be taken, you may be charged and penalties imposed including fines, imprisonment and/or closure of premises.

Should you have any questions, please do not hesitate to contact the Porcupine Health Unit at 1-800-461-1818 or visit our website: www.porcupinehu.on.ca.

These instructions remain in effect

until amended or rescinded by me.

ENSURE STRICT COMPLIANCE WITH ALL STEP 1 RULES AND INSTRUCTIONS

1. You must familiarize yourself with all Step 1 Rules that apply to your workplace and ensure strict compliance with them, at all times, by workers and members of the public present at the workplace.
   Ontario's Step 1 Rules are contained at Schedules 6 through 10 of Ontario Regulation 82/20.[1] They may be accessed at: https://www.ontario.ca/page/emergency-information.

2. You must also familiarize yourself with all instructions issued by me that apply to your workplace and ensure strict compliance with their requirements.To date, these instructions include:

   a. The instructions set out in this document; and

b. The instructions for all workplaces across the PHU, also issued by me on June 23, 2021 and effective June 25, 2021 at 12:01 a.m. These may be accessed on the PHU website at phu.fyi/covid-step1.

3. Nothing in the Step 1 Rules or in these instructions prevents any business or organization from:
   a. providing goods by mail or other forms of delivery or making goods available for pick-up, e.g., “curbside”; and
   b. providing services online, by telephone or by other remote means.[2]

4. The following instructions are in addition to all relevant requirements of the Step 1 Rules.
5. The following businesses that engage in retail sales to the public must operate at no greater than 25% capacity:
   a. Supermarkets, grocery stores, convenience stores, indoor farmers’ markets and other stores that primarily sell food (other than restaurants, bars, food trucks, concession stands and other food or drink establishments); and
   b. Stores that sell liquor, including beer, wine and spirits (again, other than restaurants, bars, food trucks, concession stands and other food or drink establishments).
   c. All other businesses that engage in retail sales to the public must limit the number of patrons in the place of business to one person at a time.
6. All other businesses that engage in retail sales to the public must limit the number of patrons in the place of business to one person at a time.

7. Restaurants, bars, food trucks, concession stands and other food or drink establishments may open only for the purpose of providing take-out, drive-through or delivery.

8. No indoor or outdoor sports or recreational classes are permitted at any indoor or outdoor sport and recreational facilities *other than*those permitted by subsections 45(2), (3), (4) and (5) of the Step 1 Rules (e.g., for identified sports teams, child care providers, mental health/addictions support services, social services or persons with disabilities).

Lianne Catton, MD, CCFP-EM, MPH
Medical Officer of Health and Chief Executive Officer

Letter rescinding Medical Officer of Health instructions to persons responsible for businesses and organizations in Moosonee

DATE: June 29, 2021

EFFECTIVE: June 30, 2021 at 12:01 a.m.

TO:

All persons responsible for a business or organization **(workplace)** in the Town of Moosonee within the Porcupine Health Unit **(PHU)** region, where workers (including employees, those hired under third party agencies, contractors, vendors, volunteers or students and any other such persons) are present at the workplace or the public are regularly present.

Thanks to the efforts of our community members and strong support from leadership within the town of Moosonee and region, we have witnessed a steady downward trend of new COVID-19 cases, a decrease in new and active outbreaks, and a decrease in rates of hospitalizations in the Porcupine Health Unit (PHU) region including the town of Moosonee. There also continues to be good uptake of first and second doses of COVID-19 vaccines.

Effective June 30, 2021, at 12:01 a.m., I will therefore be rescinding my instructions issued June 23, 2021, and effective June 25, 2021, at 12:01 a.m. that required enhanced public health measures and restrictions in Moosonee.

While this is good news, we must not let our guard down and remember to stay committed to the public health measures to get us to the end of this pandemic.

I acknowledge and thank you for complying with provincial and local rules and requirements to protect your staff, patrons and the community at large as these have changed through the course of the pandemic and ask for your continued vigilance and commitment as we move forward.

Lianne Catton, MD, CCFP-EM, MPH
Medical Officer of Health and Chief Executive Officer
Porcupine Health Unit
Postal Bag 2012
(169 Pine Street South)
Timmins, ON P4N 8B7

Instructions from the Medical Officer of Health for Businesses and Workplaces (PHU): 2021-06-30

Date: **Tuesday, June 29, 2021**

Effective: **Wednesday, June 30, 2021 at 12:01 a.m.**

To:

All persons responsible for a business or organization **(workplace)** in the Porcupine Health Unit **(PHU)** region, where employees, those hired under third party agencies, contractors, vendors, volunteers or students and any other such persons **(workers)** are present at the workplace or the public are regularly present, with the exception of:

- A licensed child care program that is in compliance with guidance issued by the Ministry of Education;
- Health care providers and health care entities as defined in Section 77.7 of the Health Protection and Promotion Act (HPPA) who are subject to the Chief Medical Officer of Health's Directives issued under the HPPA, other than the portion of premises used for the sale of goods that are neither medication nor health related supplies in pharmacies;
- Schools and school boards licensed under the Education Act; and
- Schools and private schools within the meaning of the Education Act, that are operated in accordance with a return to school direction issued by the Ministry of Education and approved by the Office of the Chief Medical Officer of Health.

First of all, I would like to thank you for your ongoing efforts to comply with public health requirements that aim to protect your staff, patrons and other members of our community. I would also like to thank you for your continued strong commitment to encourage workers to receive their vaccinations against COVID-19.

As much as we have achieved by working together in the face of this pandemic, however, I must ask for your continued patience and support in the interests of protecting the health of our community. While our vaccination rates are strong and growing daily, continued diligence will limit the risk for all as the region moves forward.

With our enhanced measures in the PHU region, the cases, outbreaks and hospital admissions have stabilized. However confirmation of the continued presence of the Delta VOC requires continued caution and enhanced diligence as we move to lift further restrictions.

Ontario's rules for reopening under the Reopening Ontario (A Flexible Response to COVID-19) Act, 2020 that apply in the Porcupine region continue to require persons responsible for a business or organization that is open to operate the business or organization in compliance with the instructions of public health officials. This includes the following instructions issued by me in this document.

The only amendments to these instructions as originally issued effective June 25, 2021, at 12:01 a.m., is to replace references to the Step 1 Rules with more general references to Ontario's rules under the Reopening Ontario (A Flexible Response to COVID-19) Act, 2020 as these may change from time to time as we complete the steps to move to full reopening in Ontario and the Porcupine region.

Please note that these amended instructions, and the continued restrictions they impose, are temporary. They have been issued in response to the very high rates of COVID-19 transmission within the Porcupine region in this recent wave, reflecting the highly transmissible VOCs. Their sole intent is to protect the public in our communities – including workers – from the very real and ongoing threat of COVID-19 and from its related impacts on our health system. These instructions will be rescinded as soon as conditions in our region permit.

These instructions will be enforced by provincial offences officers and public health officials under one or more of the Health Protection and Promotion Act, Reopening Ontario (A Flexible Response to COVID-19) Act, 2020 and/or the Emergency Management and Civil Protection Act. Failure to comply is a provincial offence. Among enforcement actions that may be taken, you may be charged, and penalties imposed including fines, imprisonment and/or closure of premises.

Should you have any questions, please do not hesitate to contact the Porcupine Health Unit at 1-800-461-1818 or visit our website: www.porcupinehu.on.ca.

THESE INSTRUCTIONS REMAIN IN EFFECT
UNTIL AMENDED OR RESCINDED BY ME

1. **ENSURE STRICT COMPLIANCE WITH ALL STEP 1 RULES AND INSTRUCTIONS:**
    1. You must familiarize yourself with all rules under the *Reopening Ontario (A Flexible Response to COVID-19) Act, 2020* **(ROA Rules)** and instructions that apply to your workplace and ensure strict compliance with them, at all times, by workers and members of the public present at the workplace.
    2. Ontario's ROA Rules, which may change from time to time, may be accessed at: https://www.ontario.ca/page/emergency-information.
    3. Effective June 30, 2021 at 12:01 a.m., and until rescinded by me, all workplaces in the PHU region must also comply with these amended instructions issued to strengthen the implementation and monitoring of public health measures in the workplace. These additional measures are specific to the PHU region's unique circumstances, which are aimed at limiting the further spread of COVID-19 as we reopen. These additional instructions may be accessed at: phu.fyi/covid-orders
2. **PROTECT ALL YOUR WORKERS FROM COVID-19:**
    1. You must continue to implement all COVID-19 prevention measures for your sector outlined in provincial guidelines and PHU guidance (see section 2.6 below), including but not limited to screening, physical distancing, wearing of masks and eye protection, hand hygiene, infection prevention and control and a safety plan.

2. Without limiting the generality of section 2.1 above, these prevention measures must include policies and procedures implemented to ensure the following:
    i. Active verification of completed screening prior to arrival on site, equivalent to the Ontario COVID-19 self-assessment (https://covid-19.ontario.ca/screening/worker/) and immediate exclusion of all workers whose screening results require self-isolation and or testing for COVID-19;
    ii. Occupancy of the premises must be limited to only as many persons as can be accommodated such that 2m distancing between persons can be maintained;
    iii. Physical distancing of 2m between persons must be maintained in all work areas, lunchrooms, change rooms, washrooms, subject only to para iv. below;
    iv. If work arrangements or the workplace environment cannot be altered to allow the required 2m distancing at all times, the workers must be provided with appropriate personal protective equipment including procedural and medical-grade masks (3-ply) and eye protection;
    v. Signage regarding COVID-19 safety measures available from the PHU or other relevant authorities must be posted throughout the workplace premises;
    vi. Masks (and eye protection and other personal protective equipment (PPE) as appropriate) must be used correctly and consistently inside the workplace premises by all workers and visitors at all times;
    vii. Eye protection must be worn when work requires contact closer than 2m;
    viii. If workplace or some work activities are outside, ensure distancing 2m at all times when possible; masks and eye protection must be worn when within 2 metres of others;
    ix. If work involves car pooling or shared vehicles, people must sit as far apart as possible and windows should be opened for increased ventilation; masks must be worn and eye protection (where safe to do so) is recommended where distancing of 2m cannot be maintained;
    x. Train all workers, and monitor to ensure, proper donning and doffing of masks, eye protection and other PPE used in the workplace;
    xi. Availability of adequate hand hygiene supplies and;
    xii. Appropriate cleaning and disinfection of workspaces with the focus on high-touch surfaces;
3. You must support self-isolation for all workers diagnosed with COVID-19, with COVID-19 symptoms, and who are close contacts of a person with COVID-19 as determined by the PHU or another public health agency.
4. You must:
    i. Maintain current and complete records for all workers so as to be able to provide a log of all workers present at the workplace during the period directed by the PHU (including first name, last name, phone number, date and location worked and, if possible, email address);
    ii. Make this log available immediately upon request by the PHU for case and contact management purposes; and

iii. This log must be retained for a minimum of 30 days.

5. Implement workplace policies and procedures to ensure the following:
   i. Symptomatic workers should get tested as soon as possible from the date of onset of symptoms;
   ii. Workers who test positive for COVID-19 shall notify their employer immediately; and
   iii. Asymptomatic workers are encouraged to seek testing.
6. Comply with all relevant directives and guidance including those from:
   i. Porcupine Health Unit:
      - Class Order - Section 22
      - Instructions from the Medical Officer of Health
      - PHU Resources to prevent COVID-19 in the workplace
   ii. Ministry of Health
      - Sector-specific guidelines
   iii. Ministry of Labour, Training and Skills Development
      - Resources to prevent COVID-19 in the workplace
7. These requirements apply to all workplaces, including those not open to the public such as construction sites and private dwellings.

3. **COMMUNICATE TO ALL WORKERS:**
   1. That every worker symptomatic for COVID-19 should be tested as soon as possible from the date of onset of symptoms at an assessment centre approved for diagnostic testing, not at a workplace screening site; and
   2. That every worker who is COVID-19 positive, is or becomes symptomatic for COVID-19, or has been identified as a close contact (meaning high risk contact) for COVID-19 as determined by the PHU or another public health agency, is required to self-isolate by the s.22 class order issued by me under the HPPA on February 26, 2021 ("Class Order"); and
   3. Provide each worker with a copy of the Class Order.
4. **IMMEDIATELY EXCLUDE FROM THE WORKPLACE EVERY PERSON IDENTIFIED AS:**
   a. diagnosed with COVID-19; or
   b. having the signs and symptoms of COVID-19 and having been tested for COVID-19 and awaiting the results of their test; or
   c. otherwise having reasonable grounds to believe they have symptoms of COVID-19; or
   d. a close contact for COVID-19 as determined by the PHU or another public health agency.
5. **FOR EVERY PERSON IDENTIFIED IN 4. ABOVE:**
   1. Immediately reiterate the information set out in Part 3 above. The Class Order requires these persons to confine themselves to their home or isolation facility (i.e., to self-isolate) until they have fully complied with all requirements of the Class Order.
   2. The Class Order provides that persons who are advised by the PHU that they are permitted to leave their home/isolation facility or who require emergency medical attention may do so but only if and as required for those limited purposes.

3. Immediately send home the worker with COVID-19 if they are at work (workers must avoid public transportation) and support them to stay off work while they are self-isolating.
4. Clean and disinfect any surfaces the worker may have touched.
5. If the worker is already at home, direct them not to enter the workplace. The worker will be contacted by public health and will be advised when it is safe for them to return to work.

6. **IF YOU BECOME AWARE OF TWO OR MORE WORKERS WITH COVID-19 AT YOUR WORKPLACE WITHIN A 14-DAY INTERVAL:**
   1. Immediately notify the PHU at 1-800-461-1818.
7. **IF YOU BECOME AWARE OF TWO OR MORE WORKERS WITH COVID-19 AT YOUR WORKPLACE WITHIN A 14-DAY INTERVAL, OR UPON NOTIFICATION BY THE PHU:**
   1. Ensure that the following steps are taken immediately:
      i. Notify:
         - the Ontario Ministry of Labour, Training and Skills Development;
         - the workplace's joint health and safety committee or health and safety representative;
         - the worker's trade union (if applicable); and
         - any other relevant governmental or other bodies (for example, you must report any occupationally acquired illnesses to the Workplace Safety and Insurance Board within 3 days of receiving notification of the illness).
      ii. Provide contact details of the most responsible decision-maker at the workplace premises and ensure that person is immediately available to the PHU;
      iii. Be readily available for contact by the PHU to implement any additional measures immediately as required by the PHU;
      iv. Cooperate with infection prevention and control personnel and any other personnel from the PHU including allowing entry into the workplace premises for inspection and to support enhanced infection prevention and control and any other measures for public health management of the outbreak;
      v. Follow all PHU directions pertaining to case and contact management and identifying workers who need to isolate, including that all directions as specified by the PHU are communicated to workers; and
      vi. Workers of a closed workplace premises shall not work in another workplace during their period of isolation.
   2. Immediately communicate to all workers:
      i. Advise workers that two or more cases of COVID-19 at your workplace and that the PHU has been notified of the situation; include further information if and as directed by the PHU (including whether an outbreak has been declared); and
      ii. Reiterate the information set out in Part 3 above.
8. **IF YOU WISH TO IMPLEMENT WORKPLACE ANTIGEN POINT-OF-CARE TESTING FOR COVID-19:**
   1. Before initiating COVID-19 antigen point-of-care testing (antigen POCT), you must:

i. Review and familiarize yourself with the Ministry of Health's COVID-19 Guidance: Considerations for Antigen Point-of-Care Testing, as current, to ensure compliance with this document subject to para ii. below;
ii. Comply with all additional requirements set out in these instructions; and
iii. Advise the PHU of your intention to initiate antigen POCT at 1-800-461-1818.

2. Antigen POCT is no more than an additional screening tool. It must be used for screening purposes only:
   i. Antigen POCT does not prevent a person from getting COVID-19.
   ii. Antigen POCT does not replace public health measures such as vaccination, symptom screening, physical distancing, appropriate PPE (e.g., masking and eye protection) and hand hygiene. Antigen POCT is no more than an additional screening tool.
3. Antigen POCT must NOT be used for any persons (including but not limited to workers):
   i. With symptoms;
   ii. Who are close contact for COVID-19 as determined by PHU or other public health agency;
   iii. Who have previously been infected with and recovered from COVID-19;
   iv. To diagnose COVID-19 infection; or
   v. To investigate a workplace outbreak.
4. Specimen collection for all antigen POCT must be conducted in an appropriate room with adherence to all appropriate public health measures and infection prevention and control requirements including PPE.
5. All workplaces initiating antigen POCT testing must implement policies and procedures to:
   i. Inform each tested person of their results; and
   ii. Establish a process to follow if the person tests positive that includes communicating information to direct and enable the person to book a confirmatory PCR test at the local assessment centre and return-to-work requirements (for workers).
6. All positive antigen POCT test results for any person tested must be immediately reported by fax to the PHU at705-360-7324 (confidential fax number)
7. Every person who receives a positive antigen POCT result must:
   i. Self-isolate immediately;
   ii. Inform their family and household members to self-isolate immediately;
   iii. Inform their employer, if the employer is not aware of the positive result;
   iv. Immediately book an appointment at the local assessment centre to obtain laboratory-based PCR testing within 24 hours of the positive antigen POCT result;
   v. Remain in self-isolation until they receive their PCR test result:
      - Those who test negative with a PCR test obtained within 24 hours of the positive antigen POCT result and asymptomatic may come out of self-isolation and return to work;
      - Those who test negative with a PCR test obtained within 24 hours of the positive antigen POCT result but have symptoms (even mild symptoms) of COVID-19 must remain in

self-isolation in accordance with the Class Order described in section 3.2 above and follow any other public health guidance from the PHU; and

- Those who test positive with a PCR test must remain in self-isolation in accordance with the Class Order described in section 3.2 above and follow any other public health guidance from the PHU.

8. Anyone with a positive antigen POCT result who either refuses laboratory-based PCR testing, or who does not obtain testing laboratory-based PCR testing within 48 hours of the positive antigen POCT result, must not return to work and must self-isolate for 10 days from the date of the positive antigen test.

in the Affidavit of DR. DAVID McKEOWN,
affirmed this 5th day of July, 2021.

Ryan Cookson

A Commissioner for the Taking of Affidavits

INSTRUCTIONS FROM THE MEDICAL OFFICER OF HEALTH

DATE: June 29, 2021 **EFFECTIVE DATE:** June 30, 2021 at 12:01 a.m.

TO: All persons responsible for a business, organization or facility in the Region of Waterloo (ROW)

First of all, I would like to thank you for your ongoing efforts to comply with public health requirements that aim to protect your staff, patrons and other members of our community. I would like to thank you for your strong commitment to encourage workers to receive their vaccinations against COVID-19 and your efforts in facilitating their ability to do so.

We have achieved much by working together in the face of this pandemic; however, at this time I must ask for your continued patience and support in the interests of protecting the health of our community, and to give us the best chance to re-open and successfully stay open.

With strong support from Ontario's Chief Medical Officer of Health and local health care leadership including all hospital CEOs, we will be taking a more gradual approach to reopening.

We must maintain Step 1 - level restrictions for approximately two weeks to minimize increased person-to-person interactions that would grow significantly with a move to Step 2 for our community at this time.

While our vaccination rates are growing daily, other trends in public health and health system indicators are concerning:

- Our data shows that ROW has had one of the highest rates of COVID-19 transmission in the province in the month of June 2021. As of June 28, 2021, our weekly case rate per 100,000 residents is over 5 times the provincial rate;
- We have seen COVID-19 spread in multiple, different types of settings in Waterloo Region, and rising infection rates in the younger age groups, including those under 20. There are multiple COVID-19 outbreaks in workplaces across the ROW. In essence, the variant is prevalent throughout the region and is not limited to one demographic;
- The surge in cases in our community has significantly affected our local hospitals. As of June 25, 2021, 60 individuals considered infectious for COVID-19 were hospitalized (this does not count those who are no longer infectious but still require hospital care), with 27 in the intensive-care unit, and our local hospitals had begun to transfer patients out of region for care;
- We have evidence that the Delta variant, significantly more transmissible than the Alpha variant (the variant driving Ontario's third wave), is the predominant

circulating strain in RoW. Public Health Ontario has estimated that the percentage of N501Y- and E484K- cases (a proxy for the Delta variant) was 81.4% in ROW from June 8, 2021 to June 14, 2021, and 93.9% in ROW from June 15, 2021 to June 21, 2021 (https://www.publichealthontario.ca/-/media/documents/ncov/epi/covid-19-prevalence-growth-voc-mutation-epi-summary.pdf). The Province has identified the ROW as one of the delta variant hotspots in Ontario.

These trends are worrisome and require a more cautious approaching to lifting public health restrictions at this time.

At this time, I anticipate these continued Step 1 - level restrictions will remain necessary for two additional weeks after most of Ontario moves to Step 2 on June 30, 2021, remaining in place until approximately mid-July, 2021. I will regularly assess our progress against key public health and health system indicators and will report publicly on our progress.

Ontario's new Step 2 Rule continues to require persons responsible for a business or organization to operate the business or organization in compliance with the instructions of public health officials. This includes the following instructions issued by me in this document pursuant to Regulation 263/20, as amended, under the Reopening Ontario (A Flexible Response to COVID-19) Act, 2020.

These instructions will be enforced by provincial offences officers and public health officials under one or more of the *Health Protection and Promotion Act*, *Reopening Ontario (A Flexible Response to COVID-19) Act, 2020* and/or the *Emergency Management and Civil Protection Act*. Failure to comply is a provincial offence. Among enforcement actions that may be taken, you may be charged, and penalties imposed including fines, and/or closure of premises.

Should you have any questions, please do not hesitate to contact Region of Waterloo Public Health at 519-575-4400 or visit our website: www.regionofwaterloo.ca/Instructions

For additional resources for workplaces please visit our website at: https://www.regionofwaterloo.ca/en/health-and-wellness/coronavirus-resources-for-workplaces.aspx

These instructions remain in effect until amended or rescinded by me.

1. You must comply with the requirements and restrictions as set out in Appendix A herein - which are the Step 1 requirements and restrictions as set out in Ontario Regulation 82/20, Schedules 6, 7, 8, 9 and 10 - as applicable to your business, organization or facility and to the extent that they are more strict than the Step 2 requirements and restrictions as set out in Ontario Regulation 263/20, as amended.

2. (1) Without limiting section 1 and subject to sections 3 to 6 herein, no person who operates a business, organization or facility shall allow persons to attend any of the following at their business, organization or facility,

(a) an organized public event that is held indoors;

(b) a social gathering that is held indoors, including a social gathering associated with a gathering described in clause (d);

(c) an organized public event or social gathering of more than 10 people that is held outdoors, including a social gathering associated with a wedding, funeral or a religious service, rite or ceremony, but not including the wedding, funeral or a religious service, rite or ceremony itself;

(d) an indoor gathering for the purposes of a wedding, a funeral or a religious service, rite or ceremony where the number of persons occupying any particular room in a building or structure while attending the gathering exceeds 15 per cent of the capacity of the room; or

(e) an outdoor gathering for the purposes of a wedding, a funeral or a religious service, rite or ceremony where the number of persons attending the gathering exceeds the number that can maintain a physical distance of at least two metres from every other person in the space where the gathering is held.

(2) A person attending an organized public event, social gathering or a gathering for the purposes of a wedding, a funeral or a religious service, rite or ceremony shall comply with public health guidance on physical distancing.

(3) For greater certainty, subsections (1) and (2) apply with respect to an organized public event, social gathering or a gathering for the purposes of a wedding, a funeral or a religious service, rite or ceremony, even if it is held at a private dwelling.

(4) For greater certainty, the limits in clauses (1) (b) and (c) apply to a social gathering associated with a wedding, a funeral or a religious service, rite or ceremony, such as a wedding reception, while the limits that apply to the wedding, funeral or religious service, rite or ceremony itself are set out in clauses (1) (d) and (e).

(5) Clause (1) (c) does not apply with respect to an outdoor end-of-school-year celebration ceremony held by a school or private school within the meaning of the *Education Act* that is in compliance with a direction issued by the Ministry of Education and approved by the Office of the Chief Medical Officer of Health.

3. Section 2 does not apply with respect to,

(a) a gathering of members of a single household;

(b) a gathering that includes members of a household and one other person from another household who lives alone; or

(c) a gathering that includes persons described in clause (a) or (b), and a caregiver for any of those persons.

4. Section 2 does not apply with respect to a gathering in a retirement home within the meaning of the *Retirement Homes Act, 2010* if it is in compliance with the policies or guidance, if any, issued by the Retirement Homes Regulatory Authority.

5. The prohibitions on attendance at an organized public event in subsection 2 (1) do not apply with respect to attendance at a business for a purpose related to providing or receiving the goods or services provided by the business if the business is not required to close.

6. (1) This section applies with respect to gatherings for the purposes of a wedding, funeral, religious service, rite or ceremony if the persons attending the gathering, other than those conducting the service, rite or ceremony, do so in a motor vehicle.

   (2) Clause 2 (1) (e) does not apply to a gathering to which this section applies if the person follows all of the following precautions that apply:

   1. Each person attending the gathering, other than the persons conducting the service, rite or ceremony, must remain within a motor vehicle that is designed to be closed to the elements, except,
      i. where necessary to use a washroom, or
      ii. as may otherwise be necessary for the purposes of health and safety.
   2. The driver of a motor vehicle must ensure that it is positioned at least two metres away from other motor vehicles.
   3. A person who ordinarily uses a non-motorized vehicle because of their religious belief and who attends the gathering must remain within their non-motorized vehicle except where necessary to use a washroom or as may otherwise be required for the purposes of health and safety, and paragraph 2 applies with necessary modifications.

Dr. Hsiu-Li Wang, MD, FRCPC
Commissioner & Medical Officer of Health
Region of Waterloo Public Health & Emergency Services

APPENDIX A TO INSTRUCTIONS ISSUED BY THE MEDICAL OFFICER OF HEALTH FOR THE REGIONAL MUNICIPALITY OF WATERLOO ON JUNE 29, 2021

STEP 1

SCHEDULE 6
GENERAL RULES AT STEP 1

Closures

1. (1) Each person responsible for a business, or a part of a business, that is not listed in Schedule 7 or 8 shall ensure that the business, or part of the business, is closed.

(2) Each person responsible for a business, or part of a business, that is listed in Schedule 7 or 8 subject to conditions shall ensure that the business, or part of the business, either meets those conditions or is closed.

(3) Each person responsible for a place, or a part of a place, that is required to be closed by Schedule 8 shall ensure that the place, or part of the place, is closed in accordance with that Schedule.

(4) Each person responsible for a place, or a part of a place, that is listed in Schedule 8 subject to conditions shall ensure that the place, or part of a place, either meets those conditions or is closed.

(5) Each person responsible for a business or place, or part of a business or place, that does not comply with sections 2 to 11 of this Schedule shall ensure that it is closed.

(6) Despite subsections (1) to (5), temporary access to a business or place, or part of a business or place, that is required to be closed is authorized, unless otherwise prohibited by any applicable law, for the purposes of,

(a) performing work at the business or place in order to comply with any applicable law;

(b) preparing the business or place to be reopened;

(c) allowing for inspections, maintenance or repairs to be carried out at the business or place;

(d) allowing for security services to be provided at the business or place; and

(e) attending at the business or place temporarily,

(i) to deal with other critical matters relating to the closure of the business or place, if the critical matters cannot be attended to remotely, or

(ii) to access materials, goods or supplies that may be necessary for the business or place to be operated remotely.

(7) Nothing in this Order precludes a business or organization from operating remotely for the purpose of,

(a) providing goods by mail or other forms of delivery or making goods available for pick-up; and

(b) providing services online, by telephone or by other remote means.

(8) Nothing in this Order precludes a business or place from providing access to an outdoor recreational amenity that is permitted to open under section 4 of Schedule 8, including by opening such limited areas of the business or place as are necessary to enable access.

(9) Nothing in this Order precludes operations or delivery of services by the following in Ontario:

1. Any government.
2. Any person or publicly-funded agency or organization that delivers or supports government operations and services, including operations and services of the health care sector.

General compliance

2. (1) The person responsible for a business or organization that is open shall ensure that the business or organization operates in accordance with all applicable laws, including the *Accessibility for Ontarians with Disabilities Act, 2005* and the *Occupational Health and Safety Act* and the regulations made under them.

(2) The person responsible for a business or organization that is open shall operate the business or organization in compliance with the advice, recommendations and instructions of public health officials, including any advice, recommendations or instructions on physical distancing, cleaning or disinfecting.

(3) The person responsible for a business or organization that is open shall operate the business or organization in compliance with any advice, recommendations and instructions issued by the Office of the Chief Medical Officer of Health or another public health official on screening individuals by, among other things,

(a) posting signs at all entrances to the premises of the business or organization, in a conspicuous location visible to the public, that inform individuals on how to screen themselves for COVID-19 prior to entering the premises; and

(b) actively screening every person who works at the business or organization before they enter the premises of the business or organization.

(4) REVOKED: O. Reg. 440/21, s. 10 (3).

(5) The person responsible for a business or organization that is open shall ensure that any person in the indoor area of the premises of the business or organization, or in a vehicle that is operating as part of the business or organization, wears a mask or face covering in a manner that covers their mouth, nose and chin during any period when they are in the indoor area unless the person in the indoor area,

(a) is a child who is younger than two years of age;

(b) is attending a school or private school within the meaning of the *Education Act* that is operated in accordance with a return to school direction issued by the Ministry of Education and approved by the Office of the Chief Medical Officer of Health;

(c) is attending a child care program at a place that is in compliance with the child care re-opening guidance issued by the Ministry of Education;

(c.1) is attending a day camp for children that is in compliance with section 24 of Schedule 7;

(d) is receiving residential services and supports in a residence listed in the definition of "residential services and supports" in subsection 4 (2) of the *Services and Supports to Promote the Social Inclusion of Persons with Developmental Disabilities Act, 2008*;

(e) is in a correctional institution or in a custody and detention program for young persons in conflict with the law;

(f) is performing or rehearsing in a film or television production or in a concert, artistic event, theatrical performance or other performance;

(g) has a medical condition that inhibits their ability to wear a mask or face covering;

(h) is unable to put on or remove their mask or face covering without the assistance of another person;

(i) needs to temporarily remove their mask or face covering while in the indoor area,

(i) to receive services that require the removal of their mask or face covering,

(ii) to engage in an athletic or fitness activity,

(iii) to consume food or drink, or

(iv) as may be necessary for the purposes of health and safety;

(j) is being accommodated in accordance with the *Accessibility for Ontarians with Disabilities Act, 2005*;

(k) is being reasonably accommodated in accordance with the *Human Rights Code*; or

(l) performs work for the business or organization, is in an area that is not accessible to members of the public and is able to maintain a physical distance of at least two metres from every other person while in the indoor area.

(6) Subsection (5) does not apply with respect to premises that are used as a dwelling if the person responsible for the business or organization ensures that persons in the premises who are not entitled to an exception set out in subsection (5) wear a mask or face covering in a manner that covers their mouth, nose and chin in any common areas of the premises in which persons are unable to maintain a physical distance of at least two metres from other persons.

(6.1) The person responsible for a business or organization shall ensure that every person who performs work for the business or organization and whose mask or face covering is temporarily removed to consume food or drink under subclause (5) (i) (iii) is separated from every other person by,

(a) a distance of at least two metres; or

(b) plexiglass or some other impermeable barrier.

(7) For greater certainty, it is not necessary for a person to present evidence to the person responsible for a business or place that they are entitled to any of the exceptions set out in subsection (5).

(8) A person shall wear appropriate personal protective equipment that provides protection of the person's eyes, nose and mouth if, in the course of providing services, the person,

(a) is required to come within two metres of another person who is not wearing a mask or face covering in a manner that covers that person's mouth, nose and chin during any period when that person is in an indoor area; and

(b) is not separated by plexiglass or some other impermeable barrier from a person described in clause (a).

Work from home except where necessary

2.1 (1) Each person responsible for a business or organization that is open shall ensure that any person who performs work for the business or organization conducts their work remotely, unless the nature of their work requires them to be on-site at the workplace.

(2) Subsection (1) does not apply to a business or organization described in subsection 1 (9).

Capacity limits for businesses or facilities open to the public

3. (1) Subject to any other provisions set out in this Order, the person responsible for a place of business or facility that is open to the public shall limit the number of members of the public in the place of business or facility so that,

(a) the members of the public are able to maintain a physical distance of at least two metres from every other person in the business or facility; and

(b) the total number of members of the public in the business or facility at any one time does not exceed 50 per cent capacity, as determined in accordance with subsection (2).

(2) For the purposes of this Order, the maximum number of members of the public permitted in a business or facility that is operating at 50 per cent capacity is determined by taking the total square metres of floor area accessible to the public in the business or facility, not including shelving and store fixtures, dividing that number by 8 and rounding the result down to the nearest whole number.

(3) For the purposes of this Order, the maximum number of members of the public permitted in a business or facility that is operating at 25 per cent capacity is determined by taking the total square metres of floor area accessible to the public in the business or facility, not including shelving and store fixtures, dividing that number by 16 and rounding the result down to the nearest whole number.

(3.1) For the purposes of this Order, the maximum number of members of the public permitted in a business or facility that is operating at 15 per cent capacity is determined by taking the total square metres of floor area accessible to the public in the business or facility, not including shelving and store fixtures, dividing that number by 26.67 and rounding the result down to the nearest whole number.

(4) For greater certainty, subsection (1) does not require persons who are in compliance with public health guidance on households to maintain a physical distance of at least two metres from each other while in a place of business or facility.

(5) The person responsible for a place of business or facility that engages in retail sales to the public must post a sign in a conspicuous location visible to the public that states the maximum capacity they are permitted to operate under.

(6) Subsection (1) does not apply to schools and private schools within the meaning of the *Education Act* that are,

(a) operating in accordance with a return to school direction issued by the Ministry of Education and approved by the Office of the Chief Medical Officer of Health; or

(b) operated by,

(i) a band, a council of a band or the Crown in right of Canada,

(ii) an education authority that is authorized by a band, a council of a band or the Crown in right of Canada, or

(iii) an entity that participates in the Anishinabek Education System.

Requirements that apply to individuals

4. (1) Every person on the premises of a business or organization that is open shall wear a mask or face covering in a manner that covers their mouth, nose and chin during any period in which they are in an indoor area of the premises.

(2) Every person shall wear a mask or face covering in a manner that covers their mouth, nose and chin during any period in which they are,

(a) in attendance at an organized public event or gathering permitted by this Order; and

(b) within two metres of another individual who is not part of their household.

(3) Subsections (1) and (2) do not require a person to wear a mask or face covering if they are subject to an exception set out in subsection 2 (5).

(4) Every member of the public in a place of business or facility that is open to the public, and every person in attendance at an organized public event or gathering permitted by this Order, shall maintain a physical distance of at least two metres from every other person, except from their caregiver or from members of the person's household.

(5) The physical distancing described in subsection (4) is not required,

(a) where necessary to complete a transaction or to receive a service, if the member of the public wears a mask or face covering in a manner that covers

their mouth, nose and chin or is subject to an exception set out in subsection 2 (5);

(a.1) when attending a day camp for children that is in compliance with section 24 of Schedule 7;

(b) when passing one another in a confined location, such as in a hallway or aisle, if the member of the public wears a mask or face covering in a manner that covers their mouth, nose and chin or is subject to an exception set out in subsection 2 (5); and

(c) in situations where another provision of this Order expressly authorizes persons to be closer than two metres from each other.

(6) For greater certainty, nothing in subsection (5) affects the obligation of persons who provide services to comply with subsection 2 (8).

(7) No person shall use an indoor or outdoor recreational amenity that is required to close under this Order.

Physical distancing and masks or face coverings in lines, etc.

5. (1) The person responsible for a business or place that is open must not permit patrons to line up or congregate outside of the business or place unless they are maintaining a physical distance of at least two metres from other groups of persons.

(2) The person responsible for a business or place that is open must not permit patrons to line up inside the business or place unless they are,

(a) maintaining a physical distance of at least two metres from other groups of persons; and

(b) wearing a mask or face covering in a manner that covers their mouth, nose and chin, unless they are entitled to any of the exceptions set out in subsection 2 (5).

(3) This section does not apply with respect to day camps for children that are in compliance with section 24 of Schedule 7.

Safety plan

6. (1) The person responsible for a business that is open shall prepare and make available a safety plan in accordance with this section, or ensure that one is prepared and made available.

(2) The safety plan shall describe the measures and procedures which have been implemented or will be implemented in the business to reduce the transmission risk of COVID-19.

(3) Without limiting the generality of subsection (2), the safety plan shall describe how the requirements of this Order will be implemented in the location including by screening, physical distancing, masks or face coverings, cleaning and disinfecting of surfaces and objects, and the wearing of personal protective equipment.

(4) The safety plan shall be in writing and shall be made available to any person for review on request.

(5) The person responsible for the business shall ensure that a copy of the safety plan is posted in a conspicuous place where it is most likely to come to the attention of individuals working in or attending the business.

7. REVOKED: O. Reg. 440/21, s. 10 (8).

Meeting or event space

8. (1) The person responsible for a business or place that is open may only rent out meeting or event space if the meeting or event space is only rented out,

(a) for a day camp for children described in section 24 of Schedule 7;

(b) to a provider of child care within the meaning of the *Child Care and Early Years Act, 2014*;

(c) for the purpose of the provision of social services;

(d) for the purpose of collective bargaining, so long as no more than ten people are permitted to occupy the rented space;

(e) for the purpose of delivering or supporting the delivery of court services;

(f) for operations by or on behalf of a government;

(g) for the purpose of delivering or supporting the delivery of government services;

(h) for the purpose of delivering or supporting mental health support services or addictions support services, so long as no more than ten people are permitted to occupy the rented space; or

(i) for the purpose of conducting in-person examinations for the registration, licensing or accreditation of persons in any of the fields or occupations described in subsection 2 (2) of Schedule 8, so long as no more than 50 students are permitted to occupy the rented space.

(1.1) The person responsible for a business or place that rents out meeting or event space must ensure that the business or place actively screens individuals in accordance with the advice, recommendations and instructions of the Office of the Chief Medical Officer of Health before they enter the indoor premises of the business or place.

(2) The person responsible for a business or place that is open shall,

(a) record the name and contact information of every member of the public who attends a meeting or event;

(b) maintain the records for a period of at least one month; and

(c) only disclose the records to a medical officer of health or an inspector under the *Health Protection and Promotion Act* on request for a purpose specified in section 2 of that Act or as otherwise required by law.

(3) Subsection (2) does not apply to the rental of meeting or event space for the purpose of delivering or supporting the delivery of court services.

9. REVOKED: O. Reg. 440/21, s. 10 (9).

Driving instruction

10. (1) The person responsible for a business or place shall ensure that no in-person driving instruction is provided by or at the business or place.

(2) Subsection (1) does not apply to in-person driving instruction for drivers of commercial motor vehicles,

(a) where the instruction is part of the Ontario Driver Certification Program administered by the Ministry of Transportation and involves the operation of motor vehicles for which,

(i) a class of driver's licence other than Class G, G1, G2, M, M1 or M2 is required, or

(ii) an air brake endorsement is required; or

(b) that is provided by a private career college that is in compliance with section 2 of Schedule 8.

(3) In this section,

"commercial motor vehicle" has the same meaning as in subsection 1 (1) of the *Highway Traffic Act*.

Cleaning requirements

11. (1) The person responsible for a business or place that is open shall ensure that,

(a) any washrooms, locker rooms, change rooms, showers or similar amenities made available to the public are cleaned and disinfected as frequently as is necessary to maintain a sanitary condition; and

(b) any equipment that is rented to, provided to or provided for the use of members of the public must be cleaned and disinfected as frequently as is necessary to maintain a sanitary condition.

(2) For greater certainty, clause (1) (b) applies to computers, electronics and other machines or devices that members of the public are permitted to operate.

Professional and elite amateur sports

12. (1) In this section,

"Framework" means the document titled "Return-to-Play Framework for Professional and Elite Amateur Sport Leagues and Events" approved by the Office of the Chief Medical Officer of Health under subsection (2), as amended from time to time; ("cadre")

"International Single Sport Event" means an international single sport event hosted by a national sport organization that is either funded by Sport Canada or recognized by the Canadian Olympic Committee or the Canadian Paralympic Committee; ("Manifestation internationale unisport")

"participant" means a person who is a member of a specified participant group in a return-to-play plan; ("participant")

"return-to-play plan" means a return-to-play plan for,

(a) a sport league or association listed in the Tables to subsection (3), or

(b) an International Single Sport Event. ("plan de retour au jeu")

(2) The Office of the Chief Medical Officer of Health may approve the Framework.

(3) The person responsible for a sport league or association in the Tables to this subsection shall ensure that a return-to-play plan that is consistent with the Framework has been established before that sport league or association can, in accordance with this section, return to play the sport referred to in Column 3:

TABLE 1
PROFESSIONAL SPORT LEAGUES OR ASSOCIATIONS

Column 1	Column 2 Professional Sport Leagues or Associations	Column 3 Sport

TABLE 2
ELITE AMATEUR SPORT LEAGUES OR ASSOCIATIONS

(4) Before an International Single Sport Event can return to play in accordance with this section, the person responsible for that International Single Sport Event must ensure that a return-to-play plan has been established that is,

(a) consistent with the Framework; and

(b) approved by a national sport organization that is either funded by Sport Canada or recognized by the Canadian Olympic Committee or the Canadian Paralympic Committee.

(5) The person responsible for an International Single Sport Event or a sport league or association listed in the Tables to subsection (3) must provide notice of its intent to return to play to the local Medical Officer of Health for each Public Health Unit region in which the International Single Sport Event or the sport league or association, as the case may be, intends to operate before returning to play.

(6) The return-to-play plan shall,

(a) list the businesses and places that may be used by the participants, which may include,

(i) hotels,

(ii) facilities for indoor or outdoor sports and recreational fitness activities,

(iii) businesses or places that are in hotels or facilities mentioned in subclause (i) or (ii), and

(iv) restaurants or bars;

(b) list specified groups of persons who are participants; and

(c) describe the measures and procedures which have been implemented or will be implemented in the businesses or places referred to in clause (a) to reduce the transmission risk of COVID-19.

(7) A business or place that is listed in the return-to-play plan as being available for the use of participants may open for use by participants if the business or place complies with the following conditions:

1. The business or place must operate in accordance with the return-to-play plan.
2. No spectators may be permitted at the business or place.
3. The business or place must ensure that any other conditions or requirements set out in this section are complied with on the premises of the business or place.

(8) The return-to-play plan shall be in writing and shall be made available by the person responsible for the International Single Sport Event or the sport league or association listed in the Tables to subsection (3), as the case may be, to any provincial offences officer upon request.

(9) The following provisions do not apply to the provision of goods or services to a participant by a business or place listed, in accordance with clause (6) (a), in the return-to-play plan when they are provided in accordance with the return-to-play plan:

1. Subsection 2 (5) of this Schedule, but only in respect of players and coaches in an International Single Sport Event or a sport league or association listed in the Tables to subsection (3).

2. Sections 3, 6 and 8 of this Schedule.
3. Section 45 of Schedule 7.
4. Clauses 1 (1) (a) and (b) of Schedule 9.

(10) Businesses and places listed in the return-to-play plan may provide in-person dining for participants if they meet the following conditions:

1. Participants must be seated at all times in any area of the establishment in which food or drink is permitted except,

i. while entering the area and while moving to their table,

ii. while placing or picking up an order,

iii. while paying for an order,

iv. while exiting the area,

v. while going to or returning from a washroom,

vi. while lining up to do anything described in subparagraphs i to v, or

vii. where necessary for the purposes of health and safety.

2. The person responsible for the establishment must,

i. record the name and contact information of every participant that enters an area of the establishment, unless the participant temporarily enters the area to place, pick up or pay for a takeout order,

ii. maintain the records for a period of at least one month, and

iii. only disclose the records to a medical officer of health or an inspector under the *Health Protection and Promotion Act* on request for a purpose specified in section 2 of that Act or as otherwise required by law.

3. No participant may be permitted to line up or congregate outside of the establishment unless they are maintaining a physical distance of at least two metres from other groups of persons inside or outside the establishment.
4. No participant may be permitted to line up or congregate inside the establishment unless they are,

i. maintaining a physical distance of at least two metres from other groups of persons inside or outside the establishment, and

ii. wearing a mask or face covering in a manner that covers their mouth, nose and chin, unless they are entitled to any of the exceptions set out in subsection 2 (5) of Schedule 6.

5. No participant shall dance, sing or perform music at the establishment.

(11) Hotels listed in the return-to-play plan may open meeting and event spaces and indoor pools, indoor fitness centres or other indoor recreational facilities that are part of the operation of the hotels, other than communal steam rooms, saunas and whirlpools, if the following conditions are met:

1. The hotels must ensure that the facilities are open only for the use of participants.
2. The hotels must ensure that the facilities are used in accordance with the return-to-play plan.

(12) Therapists referred to in the return-to-play plan may open for the sole purpose of providing services to players in an International Single Sport Event or in a sport league or association listed in the Tables to subsection (3), as the case may be, and shall provide such services in accordance with the return-to-play plan.

(13) Television productions relating to an International Single Sport Event or a game of a sport league or association listed in the Tables to subsection (3), as the case may be, that are in compliance with the return-to-play plan may open, and the conditions set out in paragraphs 1 to 5 of subsection 60 (1) of Schedule 7 do not apply to such television productions.

13. REVOKED: O. Reg. 440/21, s. 10 (10).

O. Reg. 96/21, s. 10; O. Reg. 117/21, s. 2; O. Reg. 126/21, s. 3; O. Reg. 144/21, s. 3; O. Reg. 162/21, s. 3; O. Reg. 216/21, s. 2; O. Reg. 313/21, s. 1; O. Reg. 440/21, s. 10; O. Reg. 482/21, s. 1; O. Reg. 489/21, s. 1.

SCHEDULE 7
BUSINESSES THAT MAY OPEN AT STEP 1

Supply chains

1. Businesses that supply businesses or places that are permitted to open within Ontario, or that supply businesses or services that have been declared essential in a jurisdiction outside of Ontario, with the support, products, supplies, systems, or services, including processing, packaging, warehousing, distribution, delivery, and maintenance necessary to operate.

Retailers

2. (1) The following businesses that engage in retail sales to the public and that meet the conditions set out in subsection (2):

1. Supermarkets, grocery stores, convenience stores, indoor farmers' markets and other stores that primarily sell food, other than establishments described in section 3.
2. Pharmacies.
3. Discount and big box retailers selling groceries.
4. Safety supply stores.
5. Businesses that primarily sell, rent or repair assistive devices, aids or supplies, mobility devices, aids or supplies or medical devices, aids or supplies.
6. Optical stores that sell prescription eyewear to the public.
7. Retail stores operated by telecommunications providers.
8. Stores, other than establishments described in section 3, that sell liquor, including beer, wine and spirits.
9. Outdoor garden centres and plant nurseries.
10. Indoor greenhouses.

(2) The business must comply with the following conditions:

1. They must limit the total number of members of the public in the place of business so that the total number of members of the public in the place of business at any one time does not exceed 25 per cent capacity, as determined in accordance with subsection 3 (3) of Schedule 6.
2. They must ensure that any music played at the place of business is not at a decibel level that exceeds the level at which normal conversation is possible.

(3) For greater certainty, paragraph 1 of subsection (1) includes stores that predominately sell one category of food.

(4) Nothing in this section permits a business located within an indoor farmer's market to exceed 15 per cent capacity for in-store shopping unless it is a business that primarily sells food.

3. (1) Restaurants, bars, food trucks, concession stands and other food or drink establishments that meet the conditions set out in subsection (2).

(2) A business described in subsection (1) may open only if it complies with the following conditions:

1. No indoor dining or buffet-style service may be provided.

2. Patrons must be seated at all times in any outdoor dining area of the establishment except,

i. while entering the area and while moving to their table,

ii. while placing or picking up an order,

iii. while paying for an order,

iv. while exiting the area,

v. while going to or returning from a washroom,

vi. while lining up to do anything described in subparagraphs i to v, or

vii. where necessary for the purposes of health and safety.

3. The outdoor dining area must be configured so that patrons seated at different tables are separated by,

i. a distance of at least two metres, or

ii. plexiglass or some other impermeable barrier.

4. The person responsible for the establishment must,

i. record the name and contact information of every patron that enters an area of the establishment, unless the patron temporarily enters the area to place, pick up or pay for a takeout order,

ii. maintain the records for a period of at least one month, and

iii. only disclose the records to a medical officer of health or an inspector under the *Health Protection and Promotion Act* on request for a purpose specified in section 2 of that Act or as otherwise required by law.

5. REVOKED: O. Reg. 440/21, s. 11 (3).

6. No patron may be permitted to line up or congregate outside of the establishment unless they are maintaining a physical distance of at least two metres from other groups of persons inside or outside the establishment.

6.1 No patron may be permitted to line up inside the establishment unless they are,

i. maintaining a physical distance of at least two metres from other groups of persons inside or outside the establishment, and

ii. wearing a mask or face covering in a manner that covers their mouth, nose and chin, unless they are entitled to any of the exceptions set out in subsection 2 (5) of Schedule 6.

7. No more than four people may be seated together at an outdoor table at the establishment unless everyone seated at the table is,

i. a member of the same household,

ii. a member of up to one other household who lives alone, or

iii. a caregiver for any member of either household.

8. The total number of patrons permitted to be seated outdoors at the establishment must be limited to the number that can maintain a physical distance of at least two metres from every other person at the establishment.
9. The person responsible for the establishment must post a sign in a conspicuous location visible to the public that states the maximum capacity they are permitted to operate under.
10. Music must not be played at a decibel level that exceeds the level at which normal conversation is possible.
11. No person shall dance, sing or perform music at the establishment.
12. If an outdoor dining area at the establishment is covered by a roof, canopy, tent, awning or other element, at least two full sides of the entire outdoor dining area must be open to the outdoors and must not be substantially blocked by any walls or other impermeable physical barriers.
13. If an outdoor dining area at the establishment is equipped with a retractable roof and the roof is retracted, at least one full side of the outdoor dining area must be open to the outdoors and must not be substantially blocked by any walls or other impermeable physical barriers.
14. The establishment must actively screen any dine-in patrons in accordance with the advice, recommendations and instructions of the Office of the Chief Medical Officer of Health before they enter the premises of the establishment.

(3) Despite subsection (2), the following establishments may provide indoor dining if they meet the conditions set out in paragraphs 1, 2, 3, 4, 6, 8.1, 9, 10, 12, and 13 of subsection 1 (1) of Schedule 2 to Ontario Regulation 263/20 made under the Act:

1. Establishments on hospital premises.
2. Establishments in airports.

3. Establishments located within a business or place where the only patrons permitted at the establishment are persons who perform work for the business or place in which the establishment is located.

(4) The physical distancing described in subsections 3 (1) and 4 (4) of Schedule 6 is not required when patrons are seated together at a table in an establishment.

(5) The capacity limits set out in clause 3 (1) (b) of Schedule 6 do not apply to outdoor dining areas in an establishment.

4. Nightclubs and strip clubs that open solely as food or drink establishments and that comply with the conditions set out in section 3.

5. (1) Shopping malls that comply with the following conditions:

1. Despite section 7, the only businesses in the shopping mall that may open for in-person retail sales to the public are,

i. businesses described in section 2, and

ii. any other businesses that have a public entrance that opens onto a street or exterior sidewalk.

2. Members of the public must only be permitted to enter the shopping mall,

i. for the purpose of accessing a business or place that is permitted to be open under this Order,

ii. for the purpose of accessing a designated location described in subsection (4) or (5),

iii. for the purpose of delivering or supporting the delivery of court services,

iv. for operations by or on behalf of a government, or

v. for the purpose of delivering or supporting the delivery of government services.

3. Members of the public who enter the shopping mall for a reason described in paragraph 2 must not be permitted to loiter in any area of the shopping mall that is not related to the purpose of their visit.

4. If a business or place in the shopping mall has a public entrance that opens onto a street or exterior sidewalk,

i. members of the public may only be permitted to enter and exit the business or place through a public entrance that opens onto a street or exterior sidewalk, and

ii. members of the public must be prohibited from entering or exiting the business or place through any entrance that opens directly into the shopping mall.

5. Any interior dining spaces inside the shopping mall, including any tables and seating in food courts, must be closed.
6. The shopping mall must ensure that any music played at the shopping mall is not at a decibel level that exceeds the level at which normal conversation is possible.
7. If the shopping mall is an indoor shopping mall, the shopping mall must actively screen individuals in accordance with the advice, recommendations and instructions of the Office of the Chief Medical Officer of Health before they enter the indoor premises of the mall.

(2) Any business in the shopping mall that is not permitted to open for in-person retail sales to the public may open for the purpose of,

(a) making sales using an alternative method of sale that does not require patrons to enter the shopping mall, including curbside pick-up or delivery; or

(b) permitting patrons to pick up items at a designated location established by the shopping mall under subsection (4) or (5).

(3) For greater certainty, paragraph 5 of subsection (1) does not prevent a restaurant, bar or other food or drink establishment within a shopping mall from opening and operating in compliance with section 3.

(4) A shopping mall may establish a single designated location inside the shopping mall for the purpose of allowing patrons to pick up an order from a business or place inside the shopping mall. Patrons may only pick up orders from the indoor designated location by making a prior appointment, and an item may only be provided for pick-up if the patron ordered the item before arriving at the business premises.

(5) A shopping mall may establish any number of designated locations outside the shopping mall for the purpose of allowing patrons to pick up an order from a business or place inside the shopping mall. Patrons may only pick up orders from the outdoor designated location by making a prior appointment, and an item may only be provided for pick-up if the patron ordered the item before arriving at the business premises.

5.1 REVOKED: O. Reg. 440/21, s. 11 (8).

5.2 (1) Businesses that meet the conditions set out in subsection (2) and that sell,

(a) motor vehicles, including cars, trucks and motorcycles;

(b) recreational vehicles, including motor homes;

(c) trailers and travel trailers;

(d) boats and other watercraft; or

(e) other motorized vehicles, including power-assisted bicycles, golf carts, scooters, snowmobiles and all-terrain vehicles.

(2) A business described in subsection (1) may only open if they meet the following conditions:

1. Members of the public must not be permitted in areas where the products described in subsection (1) are neither sold nor displayed for sale.
2. If members of the public are permitted to test drive any of the vehicles, boats or watercraft,

i. the test drive must be limited to no more than 10 minutes,

ii. a maximum of two people, including up to one sales representative, may be present in the vehicle, boat or watercraft during the test drive, and

iii. if two people who are not members of the same household are present in the vehicle during the test drive, any windows in the vehicle, boat or watercraft must be opened at all times.

6. Outdoor markets, including farmer's markets and holiday markets, that meet the following conditions:

1. They primarily sell food to the public.
2. If an area at the market is covered by a roof, canopy, tent, awning or other element, at least two full sides of the entire area must be open to the outdoors and must not be substantially blocked by any walls or other impermeable physical barriers.
3. If an area at the market is equipped with a retractable roof and the roof is retracted, at least one full side of the area must be open to the outdoors and must not be substantially blocked by any walls or other impermeable physical barriers.
4. The market must limit the number of members of the public in the place of business so that the total number of members of the public in the place of business at any one time does not exceed 25 per cent capacity, as determined in accordance with subsection 3 (3) of Schedule 6.

7. (1) Businesses not already described in sections 2 to 6 that engage in retail sales to the public and that comply with the following conditions:

1. They must limit the number of members of the public in the place of business so that the total number of members of the public in the place of business at any

one time does not exceed 15 per cent capacity, as determined in accordance with subsection 3 (3.1) of Schedule 6.

2. They must ensure that any music played at the place of business is not at a decibel level that exceeds the level at which normal conversation is possible.

(2) Despite anything else in this Order, any business that engages in retail sales to the public and that is not already described in sections 1 to 6 must comply with the conditions set out in subsection (1).

(3) Cannabis retail stores operating under the authority of a retail store authorization issued under the *Cannabis Licence Act, 2018* may open if they comply with the conditions set out in subsection (1) and provide products to patrons through in-person sales or through an alternative method of sale, such as curbside pick-up or delivery.

(4) A business that, as of December 26, 2020, was permitted to be open only in accordance with the conditions described in subsection (1) as it read on that date may only continue to be open in accordance with the conditions under that subsection as amended whether or not, after that date, it modified its operations or the type of products it sells.

(5) Despite subsection 32 (2) of Ontario Regulation 268/18 (General) made under the *Smoke-Free Ontario Act, 2017*, a person responsible for a specialty vape store as defined in that Regulation that is permitted to be open in accordance with the conditions described in subsection (1) shall not permit an electronic cigarette to be used for the purpose of sampling a vapour product in the specialty vape store.

Services

8. Rental and leasing services, including automobile, commercial and light industrial machinery and equipment rental.

9. Gas stations and other fuel suppliers.

10. Automated and self-service car washes.

11. Laundromats and drycleaners.

12. Lawn care services, snow clearing and landscaping services.

13. Security services for residences, businesses and other properties.

14. Domestic services that support children, seniors or vulnerable persons, including housekeeping, cooking, indoor and outdoor cleaning and maintenance services.

15. Vehicle and equipment repair and essential maintenance and vehicle and equipment rental services.

16. Courier, postal, shipping, moving and delivery services.

17. Funeral and related services.

18. Staffing services including providing temporary help.

19. (1) Veterinary services and other businesses that provide for the health and welfare of animals, including farms, boarding kennels, stables, animal shelters, and research facilities.

(2) For greater certainty, nothing in this Order precludes a person responsible for a boarding kennel or stable from allowing an animal's owner or their representative to visit the animal, assist in the care or feeding of the animal or, as applicable, ride the animal.

20. Businesses that provide pet services, including pet grooming services, pet sitting services, pet walking services and pet training services, including services for the training and provision of service animals.

21. (1) Child care providers, subject to subsections (2) and (3).

(2) A child care centre may open if it meets the following conditions:

1. The centre shall not operate a before or after school program on any school day for a child unless the child's school is permitted under this Order to provide in-person teaching or instruction to the child on that day.
2. The centre shall not provide child care on school days during typical school hours for a child whose school is not permitted under this Order to provide in-person teaching or instruction to the child on that day and who, immediately before April 12, 2021,

i. was enrolled in school, and

ii. was not registered to attend the centre on those days and during those hours.

3. If the Minister of Education designates a child care centre as an emergency child care centre that provides care for children of individuals listed in Schedule 10, paragraph 2 does not apply with respect to the provision of child care by the centre to the children of those individuals.

(3) A provider of authorized recreational and skill building programs shall not provide such a program to a child on a school day unless the child is enrolled in a school that is permitted under this Order to provide in-person teaching or instruction on that day.

(4) In this section,

"authorized recreational and skill building programs", "child care", "child care centre" and "child care provider" have the same meaning as in the *Child Care and Early Years Act, 2014*; ("programme autorisé de loisirs et de développement des compétences", "garde d'enfants", "centre de garde", "fournisseur de services de garde")

"school day" has the same meaning as in the *Education Act*. ("jour d'école")

21.1 Businesses providing short term rental accommodation that meet the following condition:

1. Any indoor pools, communal steam rooms, saunas or indoor whirlpools, indoor fitness centres, or other indoor recreational facilities that are part of the operation of these businesses, are closed.

22. Hotels, motels, lodges, cabins, cottages, resorts and other shared rental accommodation, including student residences, that meet the following condition:

1. Any indoor pools, communal steam rooms, saunas or indoor whirlpools, indoor fitness centres, or other indoor recreational facilities that are part of the operation of these businesses, are closed.

22.1 (1) Establishments that operate for the purposes of providing access to sensory deprivation pods that are being used for a therapeutic purpose prescribed by, or administered by, a regulated health professional and that comply with the following conditions:

1. Persons who provide services in the business must wear appropriate personal protective equipment.
2. No member of the public may be permitted to enter the premises except by appointment.
3. No member of the public may be permitted to be in the premises except for the period of time during which they are receiving sensory deprivation pod services.
4. The total number of patrons permitted indoors in the establishment must be limited to the number that can maintain a physical distance of at least two metres from every other person in the establishment, and in any event cannot exceed the lesser of,

i. five patrons, and

ii. 25 per cent capacity as determined in accordance with subsection 3 (3) of Schedule 6.

(2) Paragraph 3 of subsection (1) does not apply to a single caregiver accompanying an individual receiving the sensory deprivation pod service or to a single child of such individual.

23. Campgrounds that meet the following condition:

1. Any restaurant, indoor pool, communal steam room, sauna or indoor whirlpool, meeting room, indoor fitness centre or other indoor recreational facility on the premises must be closed to the public, except for any portion of those areas that,

i. is used to provide first aid services,

ii. is used to provide take-out or delivery service or outdoor dining in accordance with section 3,

iii. contains a washroom, or

iv. provides access to an area described in subparagraph i, ii or iii.

24. (1) Day camps for children that are operated in a manner consistent with the safety guidelines for COVID-19 for day camps produced by the Office of the Chief Medical Officer of Health.

(2) REVOKED: 345/21, s. 1 (1).

24.1 REVOKED: O. Reg. 440/21, s. 11 (17).

25. (1) Community centres and multi-purpose facilities that open to provide space for any, some or all of the following and that meet the requirements set out in subsection (2):

1. A day camp for children described in section 24.
2. A provider of child care within the meaning of the *Child Care and Early Years Act, 2014*.
3. Mental health support services or addictions support services, so long as no more than ten people are permitted to occupy the space.
4. The provision of social services.

(2) The person responsible for a community centre or multi-purpose facility that is open shall,

(a) record the name and contact information of every member of the public who attends the community centre or multi-purpose facility;

(b) maintain the records for a period of at least one month; and

(c) only disclose the records to a medical officer of health or an inspector under the *Health Protection and Promotion Act* on request for a purpose specified in section 2 of that Act or as otherwise required by law.

26. Cheque cashing services.

Financial services

27. Businesses that provide the following financial services:

1. Capital markets and related securities trading and advisory services.
2. Banking/credit union activities including credit intermediation.
3. Insurance.
4. Land registration services.
5. Pension and benefits payment services.
6. Financial services including payroll and payment processing and accounting and tax services.

28. (1) Real estate agent services that do not host, provide or support any open house events.

(2) Nothing in subsection (1) prevents a real estate agency from showing a property by appointment.

Telecommunications and IT infrastructure/service providers

29. Information Technology (IT) services, including online services, software products and the facilities necessary for their operation and delivery.

30. (1) Telecommunications providers and services (phone, internet, radio, cell phones etc.) and facilities necessary for their operation and delivery.

(2) For greater certainty, retail stores operated by telecommunications providers are required to comply with the rules set out in section 2.

31. Newspapers, radio and television broadcasting.

Maintenance

32. Maintenance, repair and property management services that manage and maintain the safety, security, sanitation and operation of institutional, commercial, industrial and residential properties and buildings.

Transportation services

33. Businesses and facilities that provide transportation services, including,

(a) transportation services provided by air, water, road and rail, including taxis and other private transportation providers; and

(b) support services for transportation services, including,

(i) logistical support, distribution services, warehousing and storage, truck stops and tow operators, and

(ii) services that support the operations and safety of transportation systems including maintenance and repairs.

34. (1) Marinas, boating clubs and other organizations that maintain docking facilities for members or patrons that meet the following condition:

1. Any clubhouse, restaurant, indoor pool, communal steam room, sauna or indoor whirlpool, meeting room, indoor fitness centre or other indoor recreational facility on the premises must be closed to the public, except for any portion of those areas that,

i. is used to provide first aid services,

ii. is used to provide take-out or delivery service or outdoor dining in accordance with section 3,

iii. contains a washroom, or

iv. provides access to an area described in subparagraph i, ii or iii.

(2) For greater certainty, nothing in this Order precludes a person responsible for a marina, boating club or other organization that maintains docking facilities for members or patrons from operating a grocery or convenience store on the premises or from providing fuel supply, watercraft repair and servicing, watercraft docking and watercraft launching services.

35. Businesses that provide and support online retail, including by providing warehousing, storage and distribution of goods that are ordered online.

Manufacturing

36. Businesses that extract, manufacture, process and distribute goods, products, equipment and materials, including businesses that manufacture inputs to other manufacturers (e.g. primary metal/steel, blow molding, component manufacturers, chemicals, etc. that feed the end-product manufacturer), regardless of whether those other manufacturers are inside or outside of Ontario, together with businesses that support and facilitate the movement of goods within integrated North American and global supply chains.

Agriculture and food production

37. Businesses that produce food and beverages, and agricultural products including plants, including by farming, harvesting, aquaculture, hunting and fishing.

38. Businesses that process, manufacture or distribute food, beverages, crops, agricultural products, animal products and by-products.

39. Businesses that support the food or agricultural products supply chains and the health and safety of food, animals and plants.

Construction

40. Construction activities or projects and related services that support construction activities or projects, including demolition services.

41. Land surveyors.

Resources and energy

42. Businesses that provide and ensure the domestic and global continuity of supply of resources, including, resource exploration, mining, forestry, aggregates, petroleum, petroleum by-products and chemicals.

43. Electricity generation, transmission, distribution and storage and natural gas distribution, transmission and storage.

Community services

44. Businesses that deliver or support the delivery of community services including,

(a) sewage treatment and disposal;

(b) collecting, transporting, storing, processing, disposing or recycling of any type of waste;

(c) potable drinking water;

(d) critical infrastructure repair and maintenance including roads, dams, bridges, etc.;

(e) environmental rehabilitation, management and monitoring, and spill clean-up and response;

(f) administrative authorities that regulate and inspect businesses;

(g) professional and social services that support the legal and justice system;
